CHAMBERS'S ENCYCLOPEDIA

A DICTIONARY OF

UNIVERSAL KNOWLEDGE FOR THE PEOPLE.

SOUND (Ger. *Sund*, according to Grimm, for *Suumd*, from the root of *Swim*), **a word signifying generally a strait or narrow sea-way; but applied specially to the strait which leads from the Cattegat into the Baltic Sea, between Sweden on the east, and the Danish island of Seeland on the west. It forms the usual passage from the north to the Baltic Sea, is 40 miles long, and nearly 3 miles broad at its narrowest part, between Helsingborg and Elsinore (q. v.). Its entrance is defended by the strong castle and fortress of Kronborg. See** ELSINORE.

SOUND DUTIES, certain dues formerly payable to the Danish government by all vessels passing the Sound or strait separating Sweden from Seeland. These duties originated in an agreement between the king of Denmark and the Hanse Towns in 1348, by which the former undertook to maintain the light-houses in the Cattegat, and the latter to pay duty for them. England became bound to pay duty by a treaty of date 1450, and other countries followed. The Sound Duties were abolished on 14th March, 1857, by a treaty between Denmark and other powers. A pecuniary compensation of £3,-386,528 was stipulated to be paid to Denmark, which was to be held bound to maintain the light-houses and superintend the pilotage of the Sound. By a separate treaty the United States paid to Denmark £79,759.

Sounding Lead.

SOUNDING is the act of ascertaining the depth of water beneath a ship or boat. It is a necessary operation when navigating a sea in which shoals or sunken rocks exist, or when approaching a shore. With the help of charts of soundings, it also assists the captain in fixing the precise point at which his ship is. The process of sounding is performed by a man, standing in the ship's chains, throwing the Lead (q. v.). In tolerably shallow water, he sounds with the hand-lead line of from 20 to 30 fathoms long, which is marked at distances of 2 or 3 fathoms by pieces of cloth or rag of different colours. When he feels the lead touch the bottom, he observes the mark next above the surface, and from it estimates the depth. Thus, if the mark 5 be close to the surface, he calls out: 'By the mark, five,' If the water come between two marks, he calculates in his mind the fraction of the interval immersed, and shouts: 'By the dip, four,' or 'By the dip, four and a half five,' which last means 4½. The hand-lead is thrown a little forward as the ship proceeds. The deep-sea line is marked every 10 fathoms, with an intermediate knot at every 5 fathoms, and may be of any length. In casting it, to obtain as vertical a measurement as possible, the ship is ordinarily hove to, and the lead cast as far as practicable in the line of her drift.

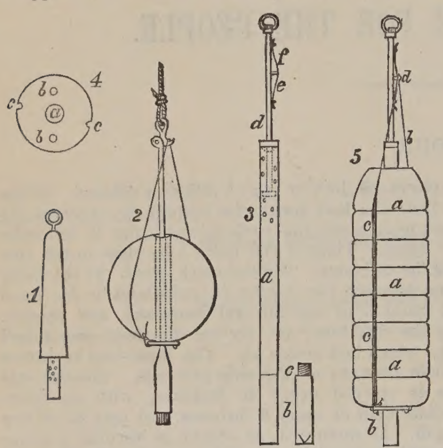
SOUNDING, DEEP SEA. Until within a few years past the term *deep sounding* was understood to be that in which a ship sounded to ascertain her position, and where the depth exceeded that which could be obtained with the lead thrown by the hand, or hand-lead; but the necessities of telegraphic communication across the ocean by means of cables containing insulated wires have caused the ocean to be measured at depths which were never before considered necessary, or even practicable.

The act of obtaining a deep-sea sounding may be said to consist of two parts: 1. To get the sinkers to the bottom as quickly as possible with the line straight up and down; and 2. To bring a portion of the soil of the bottom, as a proof, to the surface; this necessitates the use of a small but strong line, with heavy sinkers and a detaching apparatus for freeing the sinkers when they reach the bottom, as from the smallness of the line and the great friction of all passing through the water the strain of bringing the sinkers up would be too great for its strength. It may be stated that there is no difficulty whatever in obtaining a sounding and regaining the sinker with bottom specimens up to a depth of 1000 to 1200 fathoms (1½ miles) by means of a heavy lead fitted with a valved tube (fig. 1); but when the depth exceeds 2000 fath

oms, the difficulties in obtaining a correct sounding increase in a compound ratio with the depth.

The first detaching apparatus (fig. 2) was devised by Mr. Brooke, a midshipman of the United States navy. It is extremely simple and efficient. It consists of a rod with a movable hook at the upper end and a tube at the lower end. The sinker is a perforated shot through which the tube passes, and by means of a ring below the shot the weight is suspended to the hook by wire, the hook being kept up by the sounding-line; the tube is filled with cut quills. When the weight touches the ground, the line is slackened, the hook falls, and the suspending wire being freed the shot slides off; while the quills, being thrust into the soil, secure a small portion, which is brought up with the rod.

Many different kinds of detaching apparatus have been invented since, but that now used on board H.M.S. *Challenger*, in her deep-sea exploration voyage, is but a modification of the original Brooke's machine. The Hydra machine (fig. 3) consists of a tube of iron, 2½ inches in diameter, and 4½ feet in length, *a;* the lower 12 inches, *b*, is separate from but screws to the upper part at *c;* it is fitted with a butterfly valve at the lower end, to retain the bottom specimens. At the upper end of the tube is a piston-rod, *d*, which



moves freely in the tube. To the upper part of this rod is fixed a steel spring, bent in a bow, *e;* a slit in the spring is adapted to the hook, *f*, which protrudes beyond the spring when the latter is forced back. The sinkers (fig. 4) are cast-iron disks of half a cwt. each, the hole through the centre, *a*, being sufficiently large for the sounding-tube to pass through. They are made to fit each other by means of small conical protuberances on the one side and corresponding hollows on the other, *b;* so that when placed one on another, the groove, *c*, in the one weight corresponds to that on the other. The upper and lower sinkers differ a little in form.

When a sounding is to be taken, the machine is prepared as in fig. 5, a wooden stand being used for the purpose. The sinkers, *a*, *a*, are piled to the required weight, say 4 cwts.; the tube is then passed through them, and an iron ring (with a bight of iron wire attached), *b b*, is passed on the lower end of the tube and the wire led along the continuous grooves on each side of the sinkers, *c*, and the bight passed over the hook, *d*, the spring being pressed back. When the weight of the sinkers rests on the ring, and is supported by the wire, the weight keeps the spring pressed in, but as soon as the sinkers touch the ground, and the weight is relieved from the wire, the spring throws it off the hook, and the tube is drawn clear through the sinkers.

When the tube with sinkers complete is ready, it is carefully hoisted over the side, lowered gently into the sea, and eased down 100 or 200 fathoms before being let go. It is then let go, and the passing of each 100-fathoms mark is timed and recorded in a printed form made to contain all the particulars of the sounding. Sir William Thomson, F.R.S., has invented a mode of deep-sea sounding by using piano wire instead of hempen lines, which promises to obviate much of the present difficulty in deep-sea sounding.

Many very deep soundings are on record, but it is believed that the deepest well-authenticated one was obtained by Captain Nares, of H. M. S. *Challenger*, when about 80 miles to the northward of the Virgin Islands, the depth being 3875 fathoms, or nearly 4½ miles. Unfortunately, not thinking that so near the islands so great a depth would be found, only 3 cwts. of sinkers were used (the usual quantity for such extreme depths being 4 cwts.); this weight with a one-inch line took an hour and twelve minutes to reach the bottom. As the ascertainment of the sinkers reaching the bottom depends upon the time intervals, it may be stated that the line let free to run with this weight would take about 43 seconds running out the first 100 fathoms, and the time increases as nearly as possible three seconds for each successive 100 fathoms; so that when the interval is prolonged beyond this rate the sinker has reached the bottom, and it is merely the weight of the line in the water that causes the line to run out from on board the ship. On this occasion the last 50 fathoms ran out at the rate of 2 minutes 36 seconds per 100 fathoms.

An idea of the average depth of the North Atlantic Ocean may be had from the fact that of 108 soundings obtained by the *Challenger* 48 were between 1000 and 2000 fathoms, 56 between 2000 and 3000, whilst only the other 4 exceeded 3000.

SOUP (A.-S. *sup-an*, to sip or sup) is a well-known form of food, obtained either from flesh and vegetables, or from vegetables alone. When finely chopped muscular flesh (or butchers' meat) is lixiviated with cold water, and exposed to pressure, there is left a white fibrous residue consisting of muscular fibres, of connective or areolar tissue, and of vessels and nerves. This lixiviated flesh communicates no flavour to water in which it is boiled, cannot be masticated, and as Liebig observes, 'even dogs reject it.' The cold water dissolves from 16 to 24 per cent. of the dry chopped flesh. This watery infusion contains all the savory and much of the nutrient matter of the flesh, and is usually of a reddish tint from the presence of a little of the colouring matter of the blood. On gradually heating it to the boiling-point, it is observed that the albumen of the flesh (varying in amount from 2 to 14 per cent., according as the animal was old or young) separates in nearly colourless flakes when the temperature has risen to 133°, while the colouring-matter of the blood does not coagulate till the temperature rises to 158°. The liquid is now clear, and of a pale yellowish tint; and as it reddens litmus-paper, it must contain a free acid. The infusion of flesh thus prepared has the aromatic taste and all the properties of a soup made by boiling the flesh. When evaporated, it becomes dark-coloured, and finally brown; and on ceasing to lose weight, there is obtained a brown, somewhat soft mass of 'Extract of Flesh,' or 'Portable Soup,' amounting to about 12 per cent. of the weight of the original flesh, supposed to be dried. 'This extract,' says Liebig, 'is easily soluble in cold water, and when dissolved in about 32 parts of hot water, with the addition of some salt, gives to this water the taste and all the peculiar properties of an excellent soup.' The soup thus made of the flesh of different animals (as, for example, the ox and the fowl) possesses, along with the general flavour common to all soups, a peculiar taste, which distinctly recalls the smell or taste

of the roasted flesh of the animal employed. In order to obtain the strongest and best-flavoured soup, chopped flesh should be slowly heated to boiling with an equal weight of water; the boiling should only be continued for a few minutes (for prolonged boiling only gives rise to the formation of gelatin), and the soup should be then strained off from the solid residue. If, as a matter of economy, it is desirable that the meat should be left in an eatable state (which is not the case with soup made according to the preceding directions), the joint or mass of flesh should be set on the fire with cold water, which should be gently heated to boiling; the flesh thus undergoes a loss of soluble and savoury matter, while the soup becomes richer in them. The thinner the piece of flesh is, the greater is the loss which it experiences. Soup is the medicine of the convalescent, and as a means of restoring the exhausted strength, it cannot be replaced by any article of the Pharmacopœia. Its vivifying and restoring action on the appetite, on the digestive organs, the colour, and the general appearance of the sick, is most striking.

After the preceding observations on the chemistry and medicinal value of soup in the most simple form, we may proceed to notice it very briefly in its ordinary culinary relations. Most soups contain an admixture of meat and vegetables in their preparation; but many good soups can be made either entirely without the use of flesh, or with fish in place of flesh. In the former class may be placed pea-soup (which is, however, much improved if a piece of bacon enters into its composition), green-pea soup, carrot-soup, potato-soup, asparagus-soup; while for fish-soup, pike, tench, and eels are specially used. The basis of all good soups, excepting those in the preceding category, is *stock*, or broth made from all sorts of meat, bones, remains of poultry or game, &c., put together, and stewed in the *stock-pot.*

To make Liebig's *Soup for Children:* Take 1 oz. (one large table-spoonful) of seconds flour, and mix it very slowly and carefully with 10 oz. of cold skimmed milk, until the whole is smooth; add 7½ grains of bicarbonate of potash, dissolved in a tea-spoonful of water (if 60 grains of the potash be dissolved in 1 oz. of water, 1 teaspoonful must be used at a time), and then heat it gently to the boiling-point, and keep it boiling for five minutes. Stir it well while it is being heated; add to the whole fluid 1 oz. (1 large dessert-spoonful) of malt flour (malt ground in a coffee-mill and sieved), mixed with 2 oz. of water, and stir it well. Cover the pan, and let it stand for half an hour in water which is nearly boiling, so as to keep the fluid warm; then strain through a fine sieve, and bottle it. This quantity is sufficient for a day's supply for a child under two years of age, and a quart of milk should be added to it.

SOUTANE (Ital. *sottana*, Fr. *soutane*, Lat. *talaris*, i. e., *vestis*, 'a garment reaching to the ankles'), the name usually given in France and Italy to the outer garment worn in civil life (commonly with a flowing over-dress or robe) by Roman Catholic ecclesiastics, when the strict law of clerical costume is in force; and also ordered to be worn under the priestly robes used in the public ministerial offices of the clergyman. In England, it was called cassock. It is not peculiar to bishops, priests, or even to clerics in holy orders, but may be worn by all who have received even the TONSURE (q. v.). Indeed, the Council of Trent (*Dic. de Reform*, sess. 23, c. vi.) declares that no cleric shall be held entitled to the 'privilege of clerics,' unless he shall wear the soutane. The colour for the secular clergy is commonly black; but dignitaries wear other colours. Thus, the pope wears a white—cardinals, a red—bishops, a violet—many canons, a blue soutane. Its use as obligatory was very general in former times, but it is much less universal than it was thirty years since. It is strictly required to be worn under the sacred vestments by a priest administering the sacraments, or otherwise officiating publicly.

SOUR-SOP (*Anona muricata*), a West Indian fruit tree, of the same genus with the Custard Apple (q. v.). The tree does not attain a large size, but

Sour-sop (*Anona muricata.*)

is much branched and very ornamental. The fruit is very large, often weighing two or three pounds; its pulp is white, succulent, sweet, with an agreeable acidity. The sour-sop is a pleasant and refreshing fruit, and is very much used in the West Indies, being produced in great abundance.

SOUTH, ROBERT, D.D., the son of a London merchant, was born at Hackney in 1633. His earlier education he received at Westminster School, of which Dr Busby was then master; and in 1651, he became a student at Christchurch, Oxford. In 1655 and 1657 successively, he took his degrees of Bachelor and Master of Arts; he was ordained in 1658; and in 1660, he was appointed University Orator. In this function he was fortunate enough to please the Lord Chancellor Clarendon on his installation as Chancellor of Oxford, and in reward of his complimentary periods, S. was made his domestic chaplain. In 1663, he took his degree as Doctor of Divinity; the same year saw him promoted to a prebendary stall at Westminster; and in 1670, he became a canon of Christchurch, Oxford. In 1677, Laurence Hyde, son of the Chancellor, being sent to Poland as ambassador, he was accompanied thither by S., who had been his tutor, and was the object of his warm regard. Shortly after his return, the rectory of Islip, in Oxfordshire, was conferred upon him, and he was made chaplain-in-ordinary to Charles II. He might readily now have become a bishop, but through this and the succeeding reign, he steadily continued to decline the offers of higher preferment pressed upon him. The designs of James II., tending to a Roman Catholic revival, he regarded with deep disapproval and alarm; but so strong was his sense of the duty of submission to the reigning monarch, that he declined all share in the conspiracy to oust him in favour of the Prince and Princess of Orange. When, however, the Revolution was accomplished, he gave in his adhesion to it. But, to his honour, he refused to profit in the way of preferment, by the deprivation of such of the higher dignitaries of the church as could not conscientiously go along with him in recognition of the new order of things. A stanch

and even bigoted adherent of the Church of England, he continued to wage unsparing war from the pulpit, and with his pen, against Puritanism and every other form of dissent, occasionally occupying himself with discussions more strictly theological, till in July 1716, death came to conclude his controversies. He is now chiefly remembered by his sermons: they are masterpieces of vigorous sense and sound English, and abound in lively and witty turns, not always in severely decorous consonance with the seriousness of the subject-matter. As a man, S. seems to have been of sound and estimable character; of pure life, and unblemished honesty and integrity. His entire works were sent from the Clarendon press in 7 vols. (1823), 5 vols. (1843). An edition in 2 vols. appeared at London in 1850.

SOUTHA'MPTON, a municipal and parliamentary borough, important seaport, and county of itself, in the south of Hampshire, 78 miles south-west of London by the London and South-western Railway. It occupies a peninsula at the head of Southampton Water, and between the estuary of the Test or Anton on the west and south, and the mouth of the Itchen on the east. The High Street, which is the principal thoroughfare, extends from the Bargate on the north to the shore on the south border of the town. Crossing the High Street at right angles, are many important streets, and handsome lines of new houses are found in the northern and western suburbs. S. is furnished with the usual municipal and other institutions common to all thriving towns. St Michael's Church, the oldest in the town, contains Norman tower arches, and several of the private houses are of Norman architecture. The *Domus Dei*, or God's House, dates from the end of the 12th c., and is one of the earliest hospitals in England. There are large and commodious docks, covering an area of 208 acres, and capable of floating the largest steamers, at the south-east of the town. S. is the place of departure and arrival for the steam-packets of about ten separate companies. The West India, Mediterranean, East Indian, and China mails have their station here, S. is also an important government emigration port. Its harbour is perhaps the most motley and picturesque in England, being frequently crowded with Lascars, Creoles, Arabs, &c., and on the arrival of mail-steamers, with Indian and American planters, East Indian nabobs, foreign dignitaries, naval officers, and other British and foreign officials in every variety of costume. In 1872, 1393 vessels, of 616,881 tons, entered, and 1233 vessels, of 534,138 tons, cleared the port. Ship-building and engine-making are actively carried on, and there is an extensive general trade. S. is also a fashionable resort in summer. It returns two members to the House of Commons. Pop. (1861) 46,960; (1881) 60,235.

S. supplanted the ancient Clausentum, which stood about one mile to the north-east, and its foundation is ascribed to the Anglo-Saxons. It is called Hamtune and Suth-Hamtun in the Saxon Chronicle. After the Conquest, S., from which there was ready transit to Normandy, began to prosper rapidly, and in early times it traded with Venice and Bayonne, Bordeaux and Rochelle, Cordova and Tunis. A great part of it was burned by the combined French, Spanish, and Genoese fleets in 1338, and in the following year its defences were strengthened. S. is the birthplace of Isaac Watts (to whom a monument has been erected in the West Park), and of a bard of quite a different sort—Thomas Dibdin.

SOUTHAMPTON WATER, a fine inlet, stretching north-west from the point at which the Solent and Spithead unite. It is eleven miles long, and about two miles wide. The Isle of Wight, which intervenes between the S. W. and the Channel, forms a magnificent natural breakwater. The chief rivers which fall into this inlet are the Test or Anton, the Itchen, and the Hamble.

SOUTH AUSTRALIA. Recent legislation has rendered this name a misnomer, by extending the boundaries of the colony so as to include the entire centre of the Australian continent comprised between the Southern and the Indian Oceans, and between the 129th and the 138th—141st degrees of E. long,—an area of over 900,000 sq. miles.

Character of the Soil, &c.—The northern portion of this vast territory enjoys an abundant rainfall, and is watered by numerous streams and rivers, some of them, as the Victoria and the Adelaide, navigable for a considerable distance by ships of burden. The soil is fertile, and suitable for the cultivation of tropical productions of every description. An expedition has recently been despatched to form a settlement in this region; and if Coolie labour can be obtained on reasonable terms, promises to be successful.

The great central region opened up by the explorations of Stuart and M'Kinlay, and the country to the north of lat. 33°, may be described as suited only for pastoral purposes, on account of the irregularity of the rainfall and the scarcity of permanent water; and with the exception of a few patches along the coast, the same description will apply to the country to the westward of Gulf St Vincent, in 138° E. long. The south-eastern division of the colony, comprised between lat. 33° and the Southern Ocean, and between Gulf St Vincent and the eastern boundary of the colony, includes every variety of soil, ranging from absolute sterility to the highest degree of fertility, great portion of it being probably unsurpassed by any region in its adaptability both in soil and climate for the growth of wheat, the vine, and the olive. This region is moderately timbered, the principal varieties being the gum, the stringy bark, and the pine, all extremely useful for fencing and building purposes.

Climate.—A country extending over 27° of latitude must necessarily embrace great varieties of temperature; but the climate, owing to prevailing aridity, appears to be, upon the whole, healthy, and remarkably free from epidemic diseases. The mortality, on the average of three years ending 1863, was but 16·4 in 1000, that of England being 25·4 per 1000. The mortality amongst children amounts to nearly 50 per cent. of the total mortality. The hottest months are December, January, February, and March. During these months, hot winds occasionally blow. But the same dryness of the air which accounts for the great exaltation of the temperature, renders it more endurable than might at first be supposed, and Europeans are able in the hottest weather to carry on harvest-labour without danger. Careful observations, taken in the agricultural part of the colony (i. e., south of lat. 33°), and extending over a series of years, shew the mean temperature during the four hot months to average 73·60°, and during the eight cold months, 56·3°, the extreme range being from 117° to 32°. The rainfall in the north, or purely pastoral district, is as low as 7·947 inches; whilst in the south, or agricultural district, it averages as much as 48·59 inches.

Physical Aspect.—The surface of the country alternates between open plains and wooded ranges of moderate elevation, which enclose many beautiful and fertile valleys. The principal ranges are the Flinders range, which trends northward from the east coast of Spencer Gulf to the neighbourhood of Lake Torrens, in lat. 30°, where it branches out into

numerous spurs; and the Mount Lofty range, running nearly parallel with Gulf St Vincent from its head-water in lat. 34° to its termination at Cape Jarvis. The Mount Lofty ranges rise to a height of about 2600 feet, running about north-east and south-west, having a breadth of over 15 miles. This district abounds in picturesque scenery, the summits being well wooded and the slopes of great beauty and fertility, affording eligible building-sites, and producing in the highest perfection many English fruits and vegetables, which fail to thrive on the hotter and more arid soil of the plains.

Throughout S. A., the deficiency of running water is remarkable; in fact, for nearly 1200 miles, following the indentations of the coast from the western boundary of the colony to the estuary of the Torrens, in Gulf St Vincent, not even a brook of permanent fresh water finds its way into the sea. To the eastward, this deficiency is to some extent compensated, partly by the streams which take their rise in the Mount Lofty range, the principal of which are the Torrens, the Onkaparinga, the Gawler, and the Sturt, but mainly by the Great Murray. See AUSTRALIA, VICTORIA. Unfortunately for the complete utilisation of this magnificent stream, its embouchure in long. 139° E. is exposed to the full force of the Southern Ocean, which, meeting the current, throws up a shifting bar, rendering the entrance from seaward dangerous, and practicable only for steamers drawing under 7 feet. To counteract this drawback, a railway 10 miles in length has been constructed, connecting the river with Victor Harbour, a small but well-sheltered haven situated in Encounter Bay. Another railway to connect Blanch Town, situate 150 miles up the river, with Port Adelaide, in St Vincent Gulf, is contemplated, and has been completed as far as Kapunda, 57 miles, the entire distance by this line being 95 miles, which, when completed, will secure for S. A. the full advantage of this vast inland navigation.

The principal harbours are Port Adelaide in St Vincent Gulf, Port Lincoln and Port Augusta in Spencer Gulf, Victor Harbour and Port Macdonnell on the southern coast, and Nepean Bay in Kangaroo Island. Many other bays and creeks afford sufficient shelter in ordinary weather for vessels shipping produce at different points along the Sea Road.

Mineral Wealth, &c.—The mineral wealth of S. A. is great, the principal metals being copper, lead, and iron; the last is of the finest quality, but in the absence of coal, cannot be profitably worked. The principal copper-mines are the Burra and the Kapunda, to the north-east of St Vincent Gulf; the Wallaroo and Moonta, on York's Peninsula, which intervenes between St Vincent and Spencer Gulf.

Colonisation.—The country, the conformation and physical conditions of which we have above described, was selected in 1837 as the site on which to test what was then a new principle in colonisation, known as the Wakefield Theory, from the name of its author, Edward Gibbon Wakefield. The principle may be expressed in a single sentence thus: 'The waste lands of the crown, though entirely valueless prior to the application of labour and capital, acquire value according as these elements of wealth are applied to them in due proportions or otherwise; and the proceeds of the sale of these lands, if properly administered, will suffice to defray the cost of transporting the labour required for their cultivation, at the same time relieving the mother-country from the pressure of able-bodied pauperism.' A second and scarcely less important problem in economic science was put to the test on the same occasion—viz., 'The future revenues of a new colony, supplemented, if necessary, by a lien upon the lands, afford a basis of credit available for raising funds adequate to defray the cost of outfit and first settlement, and therefore the appropriation of the taxes of this country for such purposes is unnecessary and inexpedient.' Owing partly to an unfortunate delay in putting the first settlers in possession of the lands which they had paid for, but mainly to a monopoly by the government of the labour imported by the purchase-money of those lands, production was retarded during the first three years of the settlement; and the necessaries of life, which, but for this mistaken policy, might have been produced on the spot in profuse abundance, had to be imported at enormous cost, and paid for out of capital, by which means the colony was reduced to the verge of bankruptcy. In 1841, the sound principles to illustrate which the colony was founded, were, for the first time, allowed to come into play. Government interference with the labour-market ceased; and within three years from this change of policy, breadstuffs and other agricultural products were exported from S. A. in such quantities as to glut the markets which previously supplied her necessities. From that date, the progress of the colony, notwithstanding the attractions of the adjacent gold-fields, has been remarkable. The traveller may drive for many hundreds of miles over excellent roads, amidst corn-fields and vineyards cultivated by yeomen proprietors. S. A. has become the granary of the Eastern settlements; and the subjoined statements, compiled from statistics published by government, exhibit a degree of prosperity probably unsurpassed in any country or in any age.

The waste lands are disposed of in fee-simple by public auction at the upset price of 20*s.* per acre, and lands once passed the hammer, may be purchased at that price without further competition. For pastoral purposes, lands are granted to the first applicant for a lease of 14 years at an almost nominal rent. At the expiration of the first term, the run is valued by government; and if the squatter objects to that valuation, the lease is put up to auction, and sold to the highest bidder, compensation being given to the original lessee for permanent improvements constructed by him. A clause in the pastoral leases reserves to the crown power to resume portions of the land, if required, for sale to agriculturists, or for public purposes. These regulations have worked advantageously, and under them the conflict between the squatting and agricultural interests which disturbs the adjacent colonies has been avoided. The discoverer of minerals is entitled to a lease of 14 years at 10*s.* per acre, and after the expiration of the first term, the mineral-lands are put up to public competition. Great and economical facilities for the transfer of land and general dealings therewith are afforded under an act known as the Torrens Act, from the name of the author. Under this system, the difficulties, delays, and expenses attendant on the English system of conveyancing are removed, and land is rendered as easy of transfer, mortgage, and settlement as property in shipping. The great advantages secured by S. A. under this act have caused it to be adopted throughout the Australian colonies.

Government, &c.—There are two Houses of Parliament, both elective. The whole colony is thrown into one electoral district for electing members to the Council on a low property franchise, and for a period of 12 years. Members of the Assembly are elected by universal suffrage for 3 years. Voting

for both Houses is by ballot. The executive government is dependent on parliamentary majorities, as in England. No pecuniary aid is given by government to any religion, and all churches are placed on a footing of perfect equality. The system of public education is modelled on the Irish national system.

In 1881 the population of South Australia amounted to 279,865; in 1871 to 185,626, exclusive of aborigines. In the latter year the imports were of the value of £2,158,022, and the exports £3,582,397. The exports consisted chiefly of corn, wool, and copper. In the same year the total export of corn amounted in value to £1,253,429; wool to £1,170,885, and copper to £648,569. The revenue, derived principally from the sale of crown lands and customs dues, amounted to £778,094; and the public debt, spent in reproductive works, £1,944,700. In 1871 the land under cultivation amounted to 959,006 acres, of which 604,761 were wheat, 140,316 hay, 22,912 barley, 6188 oats, 6131 acres vineyards, with 6,168,758 vines. There were then in the colony 4,400,655 sheep, 136,832 cattle, 83,744 horses, 13,977 goats, 63,826 pigs, and 367,839 poultry. More than 800,000 gallons of wine were manufactured during the same year. S. A. had 133 miles of railway in 1871: the Port Line, from Adelaide to Port Adelaide, 7½ miles; and the North Line, 125½ miles, connecting Adelaide with the Burra and the copper-mines. The colony has an extensive system of electric telegraphs. An overland line, constructed at the expense of the S. A. government and opened in 1872, runs from Adelaide to Port Darwin across Central Australia, a distance of 2000 miles, and through junction with the Anglo-Indian line connects Australia with all the great centres of civilisation. The places of worship in the colony in 1871 numbered upwards of 560, with accommodations for 110,000 persons. The number of schools, in the same year, was given as 307; of scholars, 15,791; the teachers numbered 298; 94 schools were held in trust, and the average annual cost of each scholar was £1 18*s.*; the average stipend to each teacher £100 12*s.* 2*d.*

SOUTH BEND, a city of Indiana, U. S., on the south bank of the St Josephs River, near the border of Michigan, on the Southern Railway, 85 miles east of Chicago. It contains a handsome court-house, the Catholic university of Notre Dame, Female Academy and Convent, Northern Indiana College, bank, 2 newspapers, 6 churches, and large manufactories. Pop. (1870) 7206; (1880) 13,280.

SOUTH CAROLINA. See CAROLINA, SOUTH.

SOUTHCOTT, JOANNA, a curious specimen of the religious visionary, was born in Devonshire, England, of humble parentage, about 1750. In her youth she was a domestic servant, chiefly in Exeter; joined the Methodists, and becoming acquainted with a man named Sanderson, who laid claim to the spirit of prophecy, made similar pretensions herself. She received encouragement from some weak-minded clergymen of the Church of England. In 1792, she declared herself to be the woman driven into the wilderness, the subject of the prophecy in Rev. xii. She gave forth predictions in prose and verse, and although very illiterate, wrote numerous letters and pamphlets, which, as well as her prophecies in verse, or rather in doggrel, were published, and found many purchasers, and many received her pretensions as genuine. One of her productions was the *Book of Wonders.* She also issued sealed papers to her followers, which she termed her *seals*, and which, she assured them, would protect them from the judgments of God both in this and the other world, assuring their salvation. Thousands of both sexes received them with implicit confidence, among whom were men of good education and respectable position in society. At length she imagined herself to have symptoms of pregnancy, and announced that she was to give birth, at midnight on the 19th October, 1814, to a second Shiloh, or Prince of Peace, miraculously conceived, she being then more than 60 years of age. The infatuation of her followers was such that they received this announcement with devout reverence, prepared an expensive cradle, and spent considerable sums, that all might be suitable for so great an occasion. The expected birth did not take place, but on 27th December 1814, the woman died. On a post-mortem examination, it was found that the appearance of pregnancy which had deceived others, and perhaps herself, was due to dropsy. She was privately buried in London. Her followers, however, were not to be undeceived, and continued to believe that she would rise again from her 'trance,' and appear as the mother of the promised Shiloh. In 1851, according to the census returns, there were still four congregations of Southcottians in England. Unfortunately, the census returns of 1861 afford us no information on such subjects. Some passages in her absurd prophecies are of rather a practical character, as the following: 'I am the Lord thy God and Master: Tell I—— to pay thee five pounds for expenses of thy coming up to London; and he must give thee twenty pounds to relieve the perplexity of thy handmaid and thee, that your thoughts may be free to serve me the Lord, in the care of my Shiloh.' This was published in 1820. The Lord is also made to inform his people somewhere, anxious to go to meet the Shiloh at Manchester, that travelling by the new cut is not expensive.

The history of Joanna S. herself has not much in it that is marvellous; but the influence which she exercised over others may well be deemed so, and the infatuation of her followers is hard to be understood, particularly when it is considered that some of them were men of some intelligence and of cultivated mind. Probably the secret of her influence lay in the fact that the poor creature was in earnest about her own delusions. So few people in the world are really so, that they are always liable to be enslaved by others who have convictions of any kind, however grotesque. On her deathbed, Joanna said: 'If I have been misled, it has been by some spirit, good or evil.' She knew that she was not 'hersel' (as the Scotch say), when she prophesied; but she was of too mean an order of intelligence to understand that she was mad, and therefore preferred to attribute her delusions to the Deity, or, as she said at the last moment with pathetic half-penitent vacillation, to 'some spirit, good or evil.' Poor Joanna never suspected that the spirit which played such vagaries was her own.

SOUTHERNWOOD. See ARTEMISIA.

SOUTHEY, ROBERT, was born 12th August 1774, at Bristol, in which city his father was a linen-draper. In 1788, he was sent to Westminster School by his maternal uncle, the Rev. Herbert Hill, chaplain to the English factory at Lisbon, who undertook the charge of his education, his father's pecuniary affairs having become much embarrassed. At Westminster, he much distinguished himself; but in 1792 a trivial insubordination led to his expulsion; and next year he was entered at Balliol College, Oxford, with a view to his taking orders. This, however, he ultimately declined to do, having been led by his sympathy with the French Revolution, into a considerable departure from the orthodox civil and religious standards. In 1794, he left Oxford, having published the year before, in conjunction

with his friend Robert Lovell, a small volume of poems, the first literary venture of a life thenceforward to be almost wholly devoted to literature. Shortly after, he received from Cottle, for his first poem of any length, *Joan of Arc*, the sum of £50; and in November 1795, he was married to a Miss Fricker of Bristol; Coleridge, with whom he had become intimate, on the same day marrying a sister. After passing some little time with his uncle in Portugal, engaged in a diligent study of the language and literature of that country and of Spain, he became a student of law at Gray's Inn. Here he worked at his new poem of *Madoc*, and learned nothing whatever of law, a pursuit which he speedily relinquished as hopeless. In 1801, he accepted a situation as secretary to Mr Corry, Chancellor of the Exchequer for Ireland; but finding its duties distasteful to him, he very soon threw it up, and finally betook himself to literature as his sole source of livelihood.

In 1804, he settled himself at Greta Hall, near Keswick in Cumberland, where he spent the remainder of his life, working with the regularity of a machine, happy in his family relations and his unremitting daily round of congenial, though continuous toil. His biography thence onward for forty years, till the pen dropped from his fingers, might be summarised in the list of his works, which of itself would fill a page or two. In addition to these formal publications, he wrote largely for various periodicals, notably for the *Quarterly Review*, to which, from its establishment in 1809—having now become as violently conservative in his views as in youth he had been revolutionary—he was a most constant and valued contributor.

In 1807, in consideration of his services to literature, a pension of £160 per annum was awarded him; and in 1813, on the death of Mr Pye, he succeeded him as Poet Laureate. Through Sir Robert Peel, in 1835, he received a further pension of £300, and along with it the offer of a baronetcy, which, however, he decided to decline. His first wife dying in 1837, he, two years after, was married to Miss Caroline Bowles. On March 21, 1843, he died, his few last years having for the most part been passed in a state of painful mental stupor, which incapacitated him for literary exertion.

S.'s poetry—except in a few of his shorter ballad pieces—can at no time be said to have been popular, and is now nearly forgotten. His chief works are *Madoc*, *Thalaba*, *The Curse of Kehama*, and *Don Roderick*, of which the last two are reckoned the best. In all of them are to be found noble passages, in which an ample and stately rhetoric counterfeits with surprising success the pure instinct of music; but they rather skilfully illustrate the art and technic of poetry than breathe its essential life. As a prose writer, he ranks high; his style is easy, lucid, agreeable, nicely modulated throughout, and readily rising into eloquence on suggestions of sentiment and subject. But of all his multifarious writings in this kind, his little *Life of Nelson* seems most likely to survive as a classic. The most popular of his works when produced, it continues to be admired as, within the assigned limits, an almost perfect model of biography. Other very excellent biographies, however, are those of the poet Cowper, of Bunyan, and Wesley. His Life and Correspondence, edited by his son, was published in 6 vols. (1849); and a Selection from his Letters, edited by his son-in-law, in 4 vols. (1856).

SOUTH or STEWART ISLAND, the most southern of the islands which form the British colony of New Zealand (q. v.).

SOUTHMO′LTON, a municipal borough in the north of Devonshire, 11 miles east-south-east of Barnstaple. Woollen goods are manufactured. Pop. (1871) 3978; (1881) 3340.

SOU′THPORT, a fashionable bathing-place in Lancashire, on the south shore of the estuary of the Ribble, 19 miles north of Liverpool. It is a handsome town, and is almost wholly of recent erection. There are assembly-rooms, libraries, large hotels, &c.; the sands are good, and there is an iron pier nearly a mile long. The rapidity with which S. has risen in public favour as a watering-place, is the best evidence of its salubrity and beauty. Pop. (1851) 5391; (1861) 11,303; (1870) 18,085; (1880) 32,191.

SOUTH SEA SCHEME, THE, commonly designated the SOUTH SEA BUBBLE, a term peculiarly expressive of its hollow and ephemeral splendour and sudden collapse, was originated by Harley (q. v.), Earl of Oxford, in 1711, with the view of restoring public credit, and providing for the extinction of the floating national debt, which at that time amounted to £10,000,000. This debt was taken up by a number of eminent merchants, to whom the government agreed to guarantee for a certain period the annual payment of £600,000 (being 6 per cent. interest), a sum which was to be obtained by rendering permanent a number of import duties. The monopoly of the trade to the South Seas was also secured to these merchants, who were accordingly incorporated as the 'South Sea Company,' and at once rose to a high position in the mercantile world. The wondrously extravagant ideas then generally current respecting the riches of the South American continent, were carefully fostered and encouraged by the Company, who also took care to spread the belief that Spain was prepared, on certain liberal conditions, to admit them to a considerable share of its South American trade; and, as a necessary consequence, a general avidity to partake in the profits of this most lucrative speculation sprung up in the public mind. It may be well to remark in this place, that the Company's trading projects had no other result than a single voyage of one ship in 1717, and that its prominence in British history is due entirely to its existence as a purely monetary corporation. Notwithstanding the absence of any symptoms of the carrying out of its great trading scheme, the Company had obtained a firm hold on popular favour, and its shares rose day by day; and even when the outbreak of war with Spain in 1718 deprived the most sanguine of the slightest hope of sharing in the treasures of the South Seas, the Company continued to flourish. Far from being alarmed at the expected and impending failure of a similar project—the Mississippi Scheme (q. v.)—the South Sea Company believed sincerely in the feasibility of Law's scheme, and resolved to avoid what they considered as his errors. Trusting to the possibility of pushing credit to its utmost extent without danger, they proposed, in the spring of 1720, to take upon themselves the whole national debt (at that time £30,981,712), on being guaranteed 5 per cent. per annum for 7½ years, at the end of which time the debt might be redeemed if the government chose, and the interest reduced to 4 per cent. The directors of the Bank of England, jealous of the prospective benefit and influence which would thus accrue to the South Sea Company, submitted to government a counter-proposal; but the more dazzling nature of their rival's offer secured its acceptance by parliament—in the Commons by 172 to 55, and (April 7) in the Lords by 83 to 17; Sir Robert Walpole in the former, and Lords North and Grey, the Duke of Wharton, and Earl Cowper in the latter, in vain protesting against it as involving

inevitable ruin. During the passing of their bill, the Company's stock rose steadily to 330 on April 7, falling to 290 on the following day. Up till this date, the scheme had been honestly promoted; but now, seeing before them the prospect of speedily amassing abundant wealth, the directors threw aside all scruples, and made use of every effective means at their command, honest or dishonest, for keeping up the factitious value of the stock. Their zealous endeavours were crowned with success; the shares were quoted at 550 on May 28, and 890 on June 1. A general impression having by this time gained ground that the stock had reached its maximum, so many holders rushed to realise, that the price fell to 640 on June 3. As this decline did not suit the personal interests of the directors, they sent agents to buy up eagerly; and on the evening of June 3, 750 was the quoted price. This and similar artifices were employed as required, and had the effect of ultimately raising the shares to 1000 in the beginning of August, when the chairman of the Company and some of the principal directors sold out. On this becoming known, a widespread uneasiness seized the holders of stock, every one was eager to part with his shares, and on September 12 they fell to 400, in spite of all the attempts of the directors to bolster up the Company's credit. The consternation of those who had been either unwilling or unable to part with their scrip, was now extreme; many capitalists absconded, either to avoid ruinous bankruptcy, or to secure their ill-gotten gains, and the government became seriously alarmed at the excited state of public feeling. Attempts were made to prevail on the Bank to come to the rescue by circulating some millions of Company's bonds; but as the shares still declined, and the Company's chief cashiers, the Sword-blade Company, now stopped payment, the Bank refused to entertain the proposal. The country was now wound up to a most alarming pitch of excitement; the punishment of the fraudulent directors was clamorously demanded; and parliament was hastily summoned (December 8) to deliberate on the best means of mitigating this great calamity. Both Houses, however, proved to be in as impetuous a mood as the public; and in spite of the moderate counsels of Walpole, it was resolved (December 9) to punish the authors of the national distresses, though hitherto no fraudulent acts had been proved against them. An examination of the proceedings of the Company was at once commenced; and on Walpole's proposal, nine millions of South Sea bonds were taken up by the Bank, and a similar amount by the East India Company. The officials of the Company were forbidden to leave the kingdom for twelve months, or to dispose of any of their property or effects. Ultimately, various schemes, involving the deepest fraud and villainy, were discovered to have been secretly concocted and carried out by the directors; and it was proved that the Earl of Sunderland, the Duchess of Kendal, the Countess Platen and her two nieces, Mr Craggs, M.P., the Company's secretary, Mr Charles Stanhope, a Secretary of the Treasury, and the Sword-blade Company, had been bribed to promote the Company's bill in parliament by a present of £170,000 of South Sea stock. The total amount of fictitious stock created for this and similar purposes was £1,260,000, nearly one-half of which had been disposed of. Equally flagrant iniquity in the allocation of shares was discovered, in which, among others, Mr Aislabie, the Chancellor of the Exchequer, was implicated. Of these offenders, Mr Stanhope and the Earl of Sunderland were acquitted, through the unworthy partiality of the parliament; but Mr Aislabie and the other directors who were members of the House of Commons, were expelled; most of the directors were imprisoned, and all of them suffered confiscation of their possessions. The chairman was allowed to retain only £5000 out of £183,000, and others in proportion to their share in the fraudulent transactions of the Company. At the end of 1720, it being found that £13,300,000 of real stock belonged to the Company, £8,000,000 of this was taken, and divided among the losers, giving them a dividend of 33⅓ per cent.; and by other schemes of adjustment, the pressure of loss was so fairly and widely distributed, that the excitement gradually subsided. Contemporary with this great gambling scheme were numerous other 'bubbles,' most of them based upon the most shadowy foundations, and projected for the achievement of the most frivolous and even absurd ends; but none of them rose to such importance as the South Sea Scheme, though collectively they added greatly to the general distress of the period, till they were suppressed by act of parliament, 12th July 1720.—See Coxe's *Walpole*, *Bubbler's Medley*, published by Carrington Bowles, Mackay's *Popular Delusions*, and the various histories of England during this epoch.

SOUTH SHETLAND, or NEW SOUTH SHETLAND, a group of islands and a tract of what is supposed to be mainland in the South Atlantic, about 600 miles south of Cape Horn, in lat. 60° 32′—67° 15′ S. Of the islands, which are destitute of vegetation, with the exception of a species of moss, the chief are Livingston, Cornwallis, King George, Clarence, and Elephant Islands. The most recent explorers in this region are Biscoe in 1832, and Sir J. Ross in 1842.

SOU′THWARK. See London.

SOU′THWELL, a small market-town of considerable antiquity in Notts, 12 miles north-east of Nottingham. At S., Charles I. surrendered himself to the Scotch commissioners.

SOUVA′LKY, chief town of the government of Souvalky (Poland), is situated on the left bank of the river Charnagarche, a tributary of the Niemen, 538 miles south-west of St Petersburg. Pop. 16,533.

SOUZDA′L, a town of European Russia, in the government of Vladimir, noted as being one of the oldest towns in Russia, having, according to certain accounts, been founded 606 B.C. Pop. 6919.

SO′VEREIGN, the name applied in politics to the person or body of persons in whom the legislative power of a state is vested. In limited monarchies, sovereignty is in a qualified sense ascribed to the king, who, though the supreme magistrate, is not the sole legislator. A state in which the legislative authority is not trammelled by any foreign power, is called a sovereign state. The states of the German Empire were designated *mi-souveraines*, because their sovereignty was qualified by their subordination to the imperial authority; and the same term may be applied to the states of the American Union.

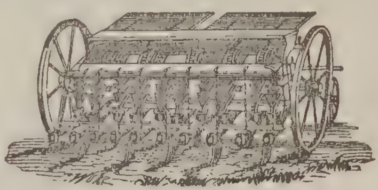
SOVEREIGN, an English gold coin of the value of twenty shillings sterling, the standard weight of which is 123·374 grains troy. The name was first applied to a gold coin issued in the reign of Henry VIII., otherwise called the double royal or rial, on which the king was represented in the royal robes. The name disappeared after a few reigns, and was revived as applicable to the gold piece of George III., issued in 1817, of the value of twenty shillings, which was substituted for the guinea, which had previously been current, of the value of twenty-one shillings.

SOWBREAD. See CYCLAMEN.

SOWERBY BRIDGE, a small manufacturing town in the West Riding of Yorkshire, three miles south-west of Halifax. It contains iron-works, malting-houses, corn-mills, worsted and cotton factories, chemical works, and dye-works; but the woollen manufacture is the principal branch of industry. Pop. (1861) 5382; (1881) 8721.

SOWING AND SOWING-MACHINES. Sowing is the deposition in the ground of the *seeds* of cultivated plants, and while agriculture was yet in a rude condition, was always performed by scattering the seeds from the hand over the prepared surface of the soil. This mode, distinguished as *hand-sowing*, is still employed in garden husbandry for sowing the seeds of kitchen vegetables; but in the more extensive operations of the farm, it has been very much superseded by the use of sowing-machines of various kinds—the broadcast sowing-machine, the drilling-machine, and the dibbling-machine; the first being employed exclusively for cereals and grasses, the other two for any kind of crop. The preparation of the soil for the reception of the seed consists in the thorough removal from it, or destruction, of weeds; in its reduction to as fine a state of division as possible by means of the plough, grubber, harrow, and roller, and in the application of the fitting manures. Attention must also be paid to the seed to be sown, that it be mature, unmixed, and each seed perfect in itself. Defect in the first two must be guarded against in the selection of seed; in the third, which is due to mechanical damage or to the presence of some of the numerous fungoid growths which infest the seeds of plants, is generally remedied by 'steeping' the seed previous to sowing it. The 'steeps' employed are of two sorts, acid and alkaline, the former acting directly on the fungoid sporules and the bruised grains, and destroying their vitality; the latter converting the oily matter which attaches the sporules to the grains into soap, and so detaching them by the aid of a little stirring. Of the acid steeps, blue vitriol or sulphate of copper ($Cu_2SO_4.5H_2O$) in the proportion of $\frac{1}{2}$ lb.—1 lb. to as much water as will cover 4 bushels of grain, is the best of all steeps, and is the one most commonly employed; the others are green vitriol or sulphate of iron ($Fe_2SO_4.7H_2O$), and various arsenical preparations. The alkaline steeps, which are inferior to the former, being more limited and less certain in their action, are putrid urine, lime-water of maximum strength, and Glauber's Salts or sulphate of soda, to the last of which lime is added with advantage. Concentrated salt brine was formerly much used and strongly recommended, but its efficacy is at best doubtful. After the seed has been steeped, it ought to be spread out on a floor in thin layers to dry, after which it should be at once sown. The sowing and the accompanying operations on the soil vary necessarily with the species of grain.

Cereals.—As above mentioned, cereals may be sown either broadcast, drilled, or dibbled. If the first method is to be adopted, the land, after being sufficiently pulverised, is again lightly ploughed, receiving what is called the seed-furrow, and the seed is then sown either by hand or by the broadcast machine. This machine consists of a triangular frame with the apex to the front, supported on three wheels, and carrying a long wooden box of the form of a triangular prism, set with a flat side—the lid—uppermost. This box, which is placed at right angles to the line of draught, is furnished with a row of small holes at the bottom, about 7 inches apart; and a little above this row is placed a longitudinal spindle, carrying a set of hard circular brushes, one opposite each hole, and deriving a rotatory motion from the axle of the hind wheels. The size of the apertures can be adjusted to the desired quantity of seed per acre, by means of a movable plate outside provided with holes corresponding to those of the box. When the box is supplied with seed, and the machine set in motion, the grain drops through the holes, which are kept from clogging by the rapid rotation of the brushes. The box is made of such a length (15—18 feet) that when the horse walks in the furrow, two adjacent half-ridges are sown at once. The grain is thus deposited with much more regularity than by the best hand-sowing, far less seed is used, and 25—30 acres can be sown per day. The seed is then covered by harrowing. This machine is much used in Scotland, being better suited to hilly and uneven surfaces, and, from its more rapid execution, to a climate which more frequently interferes with agricultural operations. In England, where the climate is more favourable, and the surface more level, the drilling-machine is the favourite. The land is now prepared for sowing by as complete pulverisation as possible, and its surface is made quite even by the harrow and roller. The drill (fig.), which in the arrangement of some of



Corn-drill.

its essential parts corresponds to the broadcast machine, differs from it in being furnished with a set of coulters, which are hollowed behind to enclose the lower ends of a corresponding set of tin tubes, whose upper ends are fixed opposite to the holes in the seed-box. By this machine, a series of furrows of uniform depth are made by the coulters; into these furrows the seed is conveyed by means of the tin tubes, and is then covered over by the harrows, one double turn being generally sufficient. The spindle inside the seed-box is provided with grooved cylinders or pinions in place of brushes, and the seed-rows are generally made about 10—12 inches apart. The advantages of this machine over the former consist in the greater regularity of deposition of the seed, which admits of hoeing and other cleaning operations during the early period of growth; in the uniform depth at which the seed is planted, so that none of it is lost by being buried; in the protection of the operation from the disturbing influence of winds; in the saving of seed and greater yield of grain; it being often found that if drilled seed be to broadcast, in quantity, as 2 to 3, their respective yields are nearly as 5 to 4. The benefits of drilling are more noticeable with autumn-sown crops, and on poor or light soil. But it has one disadvantage: a 9-foot drill (the largest size), cannot sow more than 10—12 acres per day, and employs more men and horses than the simpler machine.

The third method of sowing, by dibbling, is employed chiefly on the light soils in the south of England, and even there not generally, at least in the case of cereals, so that a minute description of the machines by which the operation is effected is unnecessary. Suffice it to mention that dibbling

only requires about one-third of the seed which is necessary in drilling, and presents still greater opportunities for weeding and stirring the soil in the early stages of growth; but is attended with various important defects, and is more expensive.

When a cereal crop is to be followed by grass, the grass seeds are sown some time after the other crop, by a broadcast machine.

Beans.—The sowing of this crop (see BEAN) is performed by means of the *bean-barrow*, a machine the same in structure as the drilling-machine for corn, but wanting the coulters, and having only three tubes, through which the seeds fall. Peas are frequently sown along with beans, the latter acting as a support to the former, and the two together better preventing the growth of weeds.

Turnips.—For this crop the ground must be more thoroughly cleaned and broken down than for any other; after which it is formed into drills 27 inches apart, which are then supplied with manure and covered in the same way as after bean-sowing. The new ridges thus formed being directly above the manure, the seeds are sown on the top of each ridge by means of the *turnip-drill.* This machine, instead of a seed-box of the ordinary form, has two tin or tinned-iron barrels, placed on a spindle. Each cylinder has a row of holes round its middle circumference, the row being covered by a circular sliding collar of thin metal, perforated with corresponding holes, and like the iron bar of the corn-drill, capable of modifying to any extent the outflow of seed. Each seed-box has its corresponding seed-tube and hollow coulter, as in the corn-drill; but the turnip-machine has in addition a large roller in front of the coulters, for compressing the crests of the ridges, and two light rollers attached behind, which slightly compress the earth raised by the coulters, and cover the seeds. The quantity of seed sown is about 2 lbs. of globe or yellow, and 3 to 4 lbs. of Swedish turnips to the acre.

SOW THISTLE (*Sonchus*), a genus of plants of the natural order *Compositæ*, suborder *Cichoraceæ*, having an imbricated involucre, swollen at the base, with two rows of unequal scales, which at length bend inwards; a naked receptacle; the fruit transversely wrinkled and without a beak, the pappus hairy and without a stalk. The COMMON S. T. (*S. oleraceus*) abounds in Britain and in most parts of Europe, as a weed in gardens and cultivated fields. It is an annual plant, delighting in rich soils, grows to the height of two or three feet, with somewhat branching stem, and small yellow flowers almost in umbels. The tender tops and leaves are much used in the north of Europe as greens.—The CORN S. T. (*S. arvensis*) is a perennial with large yellow flowers, frequent in corn-fields in Britain, and throughout great part of Europe.—Nearly allied to the genus *Sonchus* is *Mulgedium*, to which belongs the ALPINE BLUE S. T. (*M. alpinum*), the beautiful blue flowers of which adorn some of the most inaccessible spots of the mountains of Switzerland and of Scotland.

SOY is a thick and piquant sauce, made from the seeds of the SOY BEAN (*Soja hispida*), a plant of the natural order *Leguminosæ*, suborder *Papilionaceæ*, so nearly allied to the genus Dolichos (q. v.) as to be often included in it. It is a native of China, Japan, and the Moluccas, and is much cultivated in China and Japan. It is also common in India, although, probably, not a native of that country. The seeds resemble those of the Kidney Bean, and are used in the same way. The Japanese prepare from them a substance called *Miso*, which they use as butter.

Soy is made by mixing the beans softened by boiling with an equal quantity of wheat or barley roughly ground. The mixture is covered up, and kept for 24 hours in a warm place, to ferment. The mass is then put into a pot, and covered with salt, the salt used being in quantity about equal to each of the other ingredients. Water is poured over it; and it is stirred, at least once a day, for two months, after which the liquor is poured off and squeezed from the mass, filtered, and preserved in wooden vessels. By long keeping, it becomes brighter and clearer. A Chinese sauce, called *Kitjap* (Ketchup), is often sold in Britain as soy, but is very inferior to the true soy.

SPA, a town of Belgium, and a watering-place of world-wide celebrity, stands in a romantic valley amid hills which form part of the Ardennes chain, 27 miles south-east of Liége, and 22 miles south-west of Aix-la-Chapelle by railway. The prettily-built town consists almost entirely of inns and lodging-houses. The chief edifices are the *Redoute*—plain outside, but handsome within, and including under one roof a theatre (open four times a week), a ball-room, gambling-rooms, &c.—and the *Vauxhall*, a second Redoute, but now little used. The mineral springs, seven in number, are all chalybeate, and contain minute quantities of iron, so combined with alkaline salts and carbonic acid gas as to be both easily digested and agreeable to the palate. They are cold, bright, and sparkling, and are efficacious in complaints of the liver, nervous diseases, dyspepsia, &c. Spa-water is exported to all quarters of the globe. The other springs are in the vicinity of the town, and most of them are situated amid picturesque plantations. S. is also famed for the manufacture of wooden toys, which are stained brown by being steeped in the mineral waters. Pop. of the town 5881. The number of visitors during the season is about 20,000, of whom half are Belgians. S. was frequented as a watering-place as early as the 14th c., and has given its name to many mineral springs.

SPACCAFORNO, a city of Sicily, province of Noto, with 7411 inhabitants. Opposite S., Roger, king of Sicily, gained a signal victory over the Saracens in 1092.

SPACE AND TIME. Space and Time being the most general conditions, forms, or attributes of all existing things, their discussion is linked with the highest problems of philosophy. Space is co-extensive with, and inseparable from, the sensible external, or Object World; time is a property both of the Object World and of the Subject Mind.

Of the so-called Innate Ideas maintained by one school of philosophy, Space and Time are the foremost examples. (Other examples are Number, Infinity, Being, Substance, Power, Personal Identity, &c.) Accordingly, it is held, on the one side, that these notions are underived, or intuitive to the mind; and, on the other side, that they arise in the course of our education or experience, like our ideas of heat, sound, colour, gravity, &c.

To begin with Space. The supporters of the innate or intuitive origin of the idea allow that it does not arise in the mind until actual objects, or extended things are presented to the senses—until we see the visible, and touch the tangible things around us; but they declare that this contact with the sensible world is only the *occasion* of our becoming conscious of what was already in the mind. Thus, Mr. Mansel says: 'Space is not properly an *innate idea*, for no idea is wholly innate; but is

is the innate element of the ideas of sense which experience calls into consciousness.' It is, in short, the superadding of some independent activity of the mind to the passive sensation. The reasons usually given for assuming an intuitive element in the idea of Space are, in the main, the reasons given for innate ideas generally; they chiefly resolve themselves into affirming the attributes of *universality* and *necessity* in such ideas, and the inadequacy of mere sensible experience to reveal these high attributes of things. Whatever is got by experience can be thought away; Space and Time cannot. Thus, it is impossible for us to receive any sensible impression of an outward object—the sun, for example—without conceiving that thing as existing in space. To use the language of Kant, Space is a form of our sensibility, or sensible perception; and as the perception itself cannot, he thinks, give this universal and inseparable form—it must be contributed by the mind. Sir W. Hamilton supposes that we may have an 'empirical' notion of Space—i. e., a notion from experience; but that Space as a 'form' is not obtained from experience, but from intuition. He does not, however, explain clearly wherein consists the difference between these two notions.

According to the opposite view, Space is an abstraction from our experience of extended things, exactly as gravity is an abstraction from gravitating bodies, and justice from just actions. We first obtain from experience a variety of impressions, in the concrete, of things possessing extension; and, next, from all these, by the usual process of abstraction, we gain a notion of extension in the abstract, or Space. A few remarks may be made on these two distinct operations, as both involve matters of controversy.

1. Before the Muscular Feelings were distinctly recognised as something superadded to the proper sensations of the senses—or the feelings of mere light, sound, &c., it was not easy to shew that, by sensible experience alone, we could perceive objects as extended, or as occupying space. The pure optical sensibility of the eye is for colour solely; the pure tactile sensibility is for softness and smartness, roughness and smoothness, &c. When, however, we make full allowance for the whole range of feeling connected with the exercise of muscular energy, there is no difficulty in accounting for the origin of such notions as Resistance (Force or Power) and Extended Magnitude. The element supposed, by the *à priori* philosophers, to be contributed by the mind itself, is, according to the other school, Muscularity, or the feeling of the putting forth of inward energy. The two senses related to our cognizance of Space—Sight and Touch, are compound senses; they involve an active energy, with its peculiar consciousness, as well as a passive sensibility; and all that is characteristic of Extension, or Space, arises through these muscular accompaniments.

2. Having perceived a great number of things as extended, with the intervals of unoccupied extension that separate these, we form an idea of extension in the abstract. The distinguishing peculiarity of this abstraction is related to *unoccupied* extension, or empty space, where we seem to have extension without anything extended; rendering the idea of Space unlike other abstract ideas, as Gravity, or Justice, which are conceivable only as embodied in gravitating things, or just actions. Still, empty space is a reality to us, inasmuch as it expresses cessation of resistance, and free scope for movement. To the senses alone, without the muscular accompaniments, Space would be a nonentity, an inconceivability; but the feeling of the sweep of the arm, or of the locomotion of the body, in passing from one point of resistance to another, is a genuine mental experience—the filling up of the interval between two tactile encounters, or between two optical pictures, with conscious activity.

The idea of TIME, continuance, or endurance, applies both to our feelings of energy put forth, and also to our sensations, emotions, and the flow of our ideas; in other words, it attaches both to the extended or Object World, and to the unextended or Subject Mind. In our muscular feelings, which represent the universe of matter and space, we discriminate a dead strain, or effort of resistance, lasting a short time, from the same strain lasting a longer time; and also a more persisting movement from a less. So in the sensations; a sound enduring a second is different to us from a sound enduring two seconds: a transitory odour is not confounded with one of greater continuance. We distinguish two bursts of wonder, terror, love, or anger, if they have been unequal in their duration. Abstracting from all these experiences of continuance in the concrete, we obtain the idea of Time; which idea, however, like other abstractions, must be conceived by us under some individual continuing thing. If we were to imagine the whole outward universe annihilated, we should still have, in our own consciousness, an instance of the continuing, and upon that we could sustain the conception of Time. See GENERALISATION.

Time is measured by Space, and Space by Time. The one is often expressed by the other, but with a certain limitation; we say 'a space of time,' but not a 'time of space.' Movement is common to both. Of passive sensations, the best for indicating time are those of Hearing.

SPADE-HUSBANDRY, COTTAGE-FARMING, AND FIELD-GARDENING, are phrases of synonymous meaning, and denote the cultivation of farm-crops on a small scale by means of the spade. This system has long been in operation in Belgium and Flanders, where the holdings average little more than five, though a few are as large as forty acres; and by steady industry and economy, even the smallest of them is capable of maintaining a family in comfort. In Great Britain cottage-farming is chiefly practised among the miners in Cornwall, who at first received leases of their coarse unreclaimed land at 2s. 6d.—5s. per acre, the lease to last for three lives. These patches of from three to five acres now number more than 6000, and have increased 400 per cent. in value. In Lincolnshire, especially on the isle of Axholme, the same system prevails; but there the soil is naturally rich and deep; yet, though the farms are many of them very small, their occupants are well off, and about one-fourth of them have become owners of the land they cultivate. The success of small-farming depends on two causes—the inexpensiveness of the stocking and implements, and the superior fertility of the soil when dug. The implements required are—spades and digging-forks of different sizes, hoes, rakes, scythe, reaping-hooks, flail, hayfork, wheelbarrow, and a few other implements equally inexpensive; the steading consists of the cottage, a cow-shed (for one or two cows), and a pig-sty; the stock, of cows, pigs, and poultry, besides household furniture; and all of these, implements, steading, and stock, may be provided for a farm of 4—6 acres at a cost of about £110. At the end of 4 or 5 years, the land being by this time brought into good condition, a clear profit of £22 annually may be expected. The superiority of the spade over the plough rests on its deeper cultivation, on its not forming a hard impermeable crust on the surface of the subsoil, as the

plough does, on its more thorough subdivision of the soil, and on its more effective burying of weeds. As a conclusive instance of this, may be given a sketch of the system pursued by the Rev. Mr Smith of Lois-Weedon, Northamptonshire, with its results. Mr Smith drilled wheat in the usual manner, dug the intervals two spits deep, so as gradually, year by year, to bring up more and more of the subsoil, and by careful keeping down of weeds, repeated stirring of the soil, and sowing the next crop in the intervals between the rows of the former, he succeeded at a total expense of £3, 14s. per acre, in obtaining a profit of £8 per acre. Mr Smith also sowed wheat in strips of three rows, with twelve inches between the rows, and intervals of three feet between the strips; and by dint of thorough digging and trenching between the rows with the spade, he succeeded for 14 successive years in producing 36 bushels of wheat annually, without the application of a particle of manure. Similar experiments have been made with success at Rothamstead in Herts, by Mr Lawes, who found, however, that proper and sufficient manuring almost doubled the crop. The subject of cottage-farming deserves serious attention in connection with the movement for ameliorating the condition, and preventing the decrease, of the rural population of the country.

SPA'DIX. See SPATHE.

SPAGNOLET'TO. See RIBERA.

SPA'HIS (the same with *Sipahi*, or Sepoy, q. v.) were the cavaliers furnished by the holders of military fiefs to the Turkish army, and formed the élite of its cavalry. The S., along with the Janizaries (q. v.), owe their organisation primarily to Orchan, the second of the Ottoman sultans, finally to Sultan Amurath I.; and when levied *en masse*, could number 140,000, but such a levy was very seldom called for. In the field, they were divided into two classes, distinguished by the colour (red and yellow) of their standards; one class had pistols and carbine, the other a bow and arrows, and both carried a sabre, lance, and *jerid*, or javelin. They were excellent irregular troops; but when European organisation was introduced into the Turkish army, they were replaced (1826) by regular horse. At the present time, the French have numerous regiments of Spahis, raised from among the native tribes of Algeria and from France in about equal proportions; the dress, especially of the indigenous soldiers, partakes very much of the Arab character. The natives are allowed to rise to any grade below that of captain; but all the superior officers are of French descent.

SPAIN (Span. *España*), a kingdom of Europe, occupying the larger portion of the great peninsula which forms the south-west corner of the European continent, reaching further south than any other European country, and further west than any except Portugal. It is bounded on the N. by the Bay of Biscay and by France, from which it is separated by the mountain ridge of the Pyrenees; on the E. and S., by the Mediterranean and Atlantic; and on the W. by the Atlantic and Portugal. Greatest length, from Fuenterrabia on the north to Tarifa on the south, 560 miles; greatest breadth, from Cape Finisterre (Land's End), the extreme point on the west, to Cape Creuze, the extreme point on the east, about 650 miles; average breadth about 380 miles. Area, including the Balearic (q. v.) and Canary Isles, 196,031 sq. m.; pop. (1877) 16,634,345. The country, including the Balearic and Canary Isles, was divided in 1834 into 49 modern provinces, though the former division, into 14 kingdoms, states, or provinces, is still sometimes

used. The following is a table of the ancient states, and of the modern provinces into which they have been divided, with their areas and populations, according to the most recent published estimates by the best authorities:

Ancient Provinces.	Modern Provinces.	Area in Eng. Sq. Miles.	Population.
NEW CASTILE.	Madrid,	2,997·2	487,482
	Toledo,	5,586·3	342,272
	Guadalajara,	4,869·3	208,638

The colonial possessions of Spain consist of the following

Colonies.	Area in Eng. Sq. Miles.	Population.
I.—AMERICA.		
Cuba (1867),	45,708	1,414,508
Porto Rico (1864),	3,582	646,362
	49,290	2,060,870
II.—ASIA AND OCEANICA.		
Philippine Islands,	65,385	4,319,269
Caroline Islands and Palaos,	915	23,580
Marianes, or Ladrones,	415	5,610
	66,715	4,348,459
III.—AFRICA.		
Guinea Islands,	465	5,590
Total,	116,470	6,384,131

Coast-line.—The entire perimeter of the country is 2080 English miles, and the coast-line, exclusive of windings, is 1317 miles long, of which 712 miles are formed by the Mediterranean, and 605 miles by the Atlantic. The north coast, from Fuenterrabia west to Cape Ortegal, is unbroken by any considerable indentation. A wall of rocks, varying in height

from 30 to 300 feet, runs along this shore; but the water, which retains considerable depth close to the beach, is not interrupted to any unusual extent by islands or rocks. The north-west coast, from Cape Ortegal south to the mouth of the river Minho —which separates the Spanish province of Galicia from Portugal—though rock-bound, is less elevated, and is much more broken than the shores washed by the Bay of Biscay; and the indentations, the chief of which are Noya Arosa and Vigo Bays, form secure and spacious harbours. From the mouth of the Guadiana, on the south, to the Strait of Gibraltar, the coast-line, though well defined, is low, sandy, and occasionally swampy. From Gibraltar to Cape Palos the shores, which are backed in part by the mountain-range of the Sierra Nevada, are rocky and high (though flats occur at intervals), are unbroken by indentations, and comprise only two harbours, those of Cartagena and Malaga. A low, and for the most part sandy, coast extends north from Cape Palos, rising into rocky cliffs and bluffs in the vicinity of Denia, but extending in sandy flats from Denia to the mouth of the Ebro. From the mouth of this river, north to the frontier of France, the coast is alternately high and low, and its principal harbours are Barcelona and Rosas.

Surface and Hydrography.—The compactness and the isolation of this country, and its position between two seas, the most famous, and commercially the most important in the world, are not more in its favour than the character of its surface, which is more diversified than that of any other country in Europe of equal extent. An immense plateau, the loftiest in the continent, occupies the central regions of S., and is bounded on the N. and W. by mountainous tracts, and on the N.-E. by the valley of the Ebro; on the E. by tracts of land frequently low, but in some parts traversed by hill-ranges; on the S. by the valley of the Guadalquivir, which intervenes between it and the Sierra Nevada (q. v.). This great plateau rises to the height of from 2000 to 3000 feet, and occupies upwards of 90,000 sq. m., or about half of the entire area of the country. The whole of the Pyrenean peninsula is divided by Spanish geographers into seven mountain ranges, of which the chief are: 1. The Cantabrian Mountains (q. v.), and the Pyrenees (q. v.), forming the most northern range; 2. The Sierra de Guadarrama, separating Leon and Old Castile from Estremadura and New Castile, and rising in the peak of Penalara 7764 feet above sea-level; 3. The Montes de Toledo, forming a part of the watershed between the Tagus and the Guadiana; 4. The Sierra Morena (q. v.), between the upper waters of the Guadiana and Guadalquivir; 5. The Sierra Nevada (q. v.), running parallel with the shores of the Mediterranean, through southern Murcia and Andalucia, and rising in its chief summits to loftier elevations than are found in any mountain-system of Europe, except that of the Alps. The several mountain-ridges, or as they are called, *Cordilleras* of S., have a general east and west direction, and between them run, in the same direction, the nearly parallel valleys or basins of the great rivers of the country, the Douro, Tagus, Guadiana, and Guadalquivir, each of which is described in its proper place.

Climate and Soil.—The climate of S., owing to the extent and configuration of the country, is exceedingly various. In the north-west (maritime) provinces, it is damp and rainy during the greater part of the year; at Madrid, which is situated about 11° south of London, and only 5° north of the shores of Africa, winters have occurred of such severity, that sentinels, while on duty, have been frozen to death; while the south and east provinces are warm in winter, and are exposed to burning winds from the south, and to an almost tropical heat in summer. Both ancient and modern geographers have adopted difference of climate as the rule for dividing the Peninsula into tracts distinct as well in soil and vegetation as in temperature. Of these tracts or zones the first and most northern may be considered as embracing Galicia, Asturias, the Basque Provinces, Navarre, Catalonia, and the northern districts of Old Castile and Aragon. In this tract, the winters are long, and the springs and autumns rainy, while north and north-east winds blow cold from the snow-covered Pyrenees. The country, which alternates with hill and dale, is plentifully watered by streams rich in fish, and meadows yielding rich pasturage abound. Corn scarcely ripens in the more exposed districts, but grain crops of all kinds are produced in others, as well as cider, wine, and valuable timber. The middle zone is formed mainly by the great central plateau, and embraces Northern Valencia, New Castile, Leon, and Estremadura, with the south parts of Old Castile and Aragon. The climate of the great part of this region is pleasant only in spring and autumn. Throughout the chilly winter, the treeless table-lands are over-swept by violent tempests, and in summer are burned up by the sun. The soil is generally fertile, and corn and wine are most abundantly produced. The southern or Bætican zone, comprising the rich country that extends between the southern wall of the central plateau and the Mediterranean shores, includes Andalucia, Murcia, and Southern Valencia. The stony rampart on the north protects it from the chilly winds of the central zone; but it is unprotected against the hot winds (the Solana, see SIMOOM) which in summer blow north from Africa, and render this season intolerable to northern Europeans. Here the winter is temperate, and the spring and autumn delightful beyond description. The descent from the cold and mountainous central regions to this tract of tropical heat and fertility affords a most striking contrast. The soil, which is artificially irrigated, is well adapted to agriculture and the cultivation of heat-loving fruits. The products comprise sugar, cotton, and rice, and the orange, lemon, and date.

Material Revival of Spain; Productions, Vegetable and Mineral.—Owing to a number of causes, S., at one time the most opulent kingdom in Europe, had, in the 18th c., lapsed into a state of complete stagnation; the spirit of enterprise seemed extinct, and ease and squalor to be preferred to labour and affluence. Before the commencement of the present century, however, the country began to throw off its lethargy, and since that time the rate at which it has been advancing toward a healthy condition of active life has become gradually accelerated. Since 1851, the onward movement of the nation has been as rapid as that of any of the great European powers. The population has greatly increased, and is increasing; agriculture, previously stagnant, is now carried on with activity and success; manufactures are multiplying rapidly; and railways, of which, in the beginning of 1848, not a mile had been constructed, are now in process of being laid out between all the great centres of population—2902 miles were in operation in 1865. A view of the increase of the population, the first basis of power, will afford an index of the growing prosperity of the country. The estimates of the population of S. for various periods between the beginning of the 16th c. and the middle of the 18th c. vary considerably; but it is certain that there was a gradual decrease of from 2,000,000 to 3,000,000 of

inhabitants between the years 1500 and 1700. With regard to later times, we have the following authentic statement:

Year.	Population.
1768,	9,159,999
1797,	10,541,221
1857,	15,464,340
1860,	15,673,536
1870,	16,835,506

It thus appears, that in about a century, the population of S. has increased over 7,000,000. Comparing the census of May 1857 with that of December 1870, we find that the provinces in which the population has most largely increased are Madrid, Barcelona, Pontevedra, Seville, Cadiz, Valencia, Alicante, Oviedo, Zaragoza, Jaen, and Guadalajara. These are for the most part maritime provinces, or such as, from their vicinity to the coast, have facilities for communication with the sea; and, this being the case, it may be fairly argued that the rapid extension of the railway system now going on will—besides acting favourably on the whole kingdom—have a specially beneficial effect upon the interior provinces. In agriculture, as well as in population, the onward movement has been remarkable. The vast mountains of the country affording for the most part only scanty crops of herbage, are utilised as pasture-grounds, and are divided into large farms. But in the warm and fertile plains, especially in localities where water is abundant, the farms are small. The number of farms in 1800 is stated to have been 677,520, of which proprietors occupied 273,760, and tenants 403,760 farms. In 1860, there were 3,426,083 farms of all sizes, of which 750,000 were occupied by tenants, and the others by proprietors. Owing to their great number, the farms must of necessity be small; but it has been ascertained that the provinces in which the property is most subdivided are the wealthiest. The figures show that the subdivision of the soil must have been in a great measure the work of recent years; and yet nearly 46 per cent. of the whole land is uncultivated. The average quantity of wine produced annually in the three years 1860—1862 inclusive, was over 134,612,000 gallons, or twice the quantity produced in 1847. In the years 1860—1862, 28,573,336 gallons, on an average, were exported, 836,000 gallons were converted into brandy, and 105,202,724 gallons were consumed within the country. For the quantity exported, the sum realised, in 1869, was £2,348,714. In 1847, the quantity of wheat exported was 7,045,775 imperial bushels; the quantity exported in 1861 was 120,012,200 bushels. 948,024 gallons of olive oil were exported in 1850; in 1861, 2,492,688 gallons, realising £813,813. But the quantity *produced* in the country is (1875) about 5,000,000 gallons a year. The following table shews the value in reals (1 real = $2\frac{1}{2}d.$) of certain of the agricultural products exported from S. to foreign countries in recent years:

Years.	Green Fruit.	Dried Fruit.	Grain, Vegetables, and Seeds.	Cork.	Saffron.	Spanish Grass.
1850,	3,958,756	87,579,143	12,354,554	18,651,265	3,227,620	2,898,490
1851—1855,	6,017,039	52,784,016	93,513,653	16,610,706	5,884,929	2,285,616
1856—1860,	18,501,517	100,523,560	42,340,691	32,405,274	7,324.758	2,276.224
1861,	19,507,531	88,828,195	61,297,818	38,496.644	8,995,000	3.445,090
1862,	47,005,919	95,997,535	30,363,377	33,450,174	18,060,090	6,929,600

The following table shews the number of cattle of different kinds, with their value in reals, according to latest returns:

Kinds of Cattle, &c.	Number of Cattle.	Value in Reals.
Black cattle,	1,869,148	884,398,948
Horses,	382.009	276,656,041
Mules,	665,472	770,983,276
Asses,	750,007	177,398,066
Sheep { Fixed in one locality,	14,341,181	525,436,366
Sheep { Migratory,	5,251,357	119,711,760
Goats,	3,145,100	132,499,239
Swine,	1,608,203	255,899.241
Camels,	1,861	2,091,970

Spanish statistics of all kinds are very imperfect; but judging from the imports of coal and iron, the manufacturing industry of the country is rapidly advancing in spite of all drawbacks. The imports of coal had risen from 75,276 tons in 1849 to 514,052 tons in 1866; besides about 316,027 (in 1863) extracted from native mines. The average quantity of iron annually imported from 1856—1860, was 11,785 tons, but in 1862, nearly double the amount was imported, in 1864, 63,335 tons, and in 1866 but 18,999 tons wrought and unwrought. The cotton manufactures of S. have been advancing with remarkable rapidity. In 1849, 233,898 cwts. of cotton were imported. This quantity increased annually until, in 1863, the quantity imported was 798,299 cwts.

Commerce, Exports, and Imports.—In 1872, the mercantile marine of S. consisted of 4326 vessels (about 100 of which were steamers), of 359,765 tons; showing a decrease of 2389 vessels and 89,671 tons from the year 1860 to 1872. In 1857, 11,024 vessels entered and cleared the ports; in 1867, the entrances and clearances numbered 17,900. The value of the foreign commerce of S. was in 1863, £27,900,000, in 1867, £21,835,000. The countries with which S. trades most extensively are France, Great Britain, Cuba, the British Possessions, and the United States, and of these countries Great Britain receives about as much as France, while the latter (owing probably to the vicinity of that country) supplies more of the imports of S. than any other state. The foreign trade of the country is carried on most extensively at the following ports, which are set down in the order of their importance: Barcelona, Cadiz, Santander, Alicante, Malaga, Valencia, Bilbao, Cartagena, San Sebastian, Elizondo, and Irun. The principal articles imported are—in the order of their importance—sugar, yarn, woollen fabrics, raw cotton, iron, machinery, coals, and dried fish; the chief articles exported are wine, metals, dried fruit, flour, bullion, green fruits, olive oil, minerals, wool, grain, cork, rags and esparto cork and salt. In the year ending December 31, 1869, produce amounting in value to £6,346,741 was imported from S. into Great Britain. Compared with the total of 1865, an increase is manifest of £1,577,464, and with that of 1868, a decrease of £244,280, wine exceeding half the entire annual aggregate in value. Almonds, grapes, nuts, oranges, lemons, and raisins are also exported in immense quantities, the value of which varies from £500,000 to £1,000,000 annually. The total imports of S. in 1869 amounted to £16,000,000; the exports in the same year, to nearly £12,000,000. Lead, quicksilver, iron pyrites, silver ore, manganese ore, copper and copper ore, figure largely in the returns for 1864. The number of Spanish vessels that entered the ports of the United Kingdom in 1864 was 319, of 106,140 tons

The exports from Cuba for the first six months of 1870 were 1,154,962 boxes, 465,684 hhds. of sugar, and 292,926 hhds. of molasses.

Railways and Roads.—In October 1848, the first Spanish railway, 18 miles in length, from Barcelona to Mataro, was thrown open to the public, and before the close of 1873, 3310 miles of railway were open for traffic, and about 1200 miles were in course of construction. The capital employed in their construction to the date of Jan. 1, 1867, was £74,689,113. In 1865, the net produce of the traffic was £2,927,450. In 1870, 74,884,999 letters were carried through the post, the destination of 69,841,785 of which was at home, 2,923,549 to the Spanish colonies, and 2,119,665 to foreign countries. The length of the telegraph lines in 1871 was 11,754 kilometres (about 7300 miles).

Army.—The army mustered (1873), according to the *Almanach de Gotha*, 216,000, of which 80,000 were in active service and 136,000 in reserve. Of the former 60,000 were infantry, 9000 cavalry, 8500 artillery, and 2500 engineers.

Navy.—The navy in 1874 consisted of 202 vessels, carrying 894 guns, as follows:

1*st Class.*—7 iron-clad frigates (145 guns); 10 screw-frigates (431 guns); 3 paddle-steamers (48 guns).

2*d Class.*—10 paddle-steamers (48 guns); 9 screw-steamers (30 guns); 2 transports.

3*d Class.*—20 screw-steamers (45 guns); 54 gunboats (54 guns); 10 paddle-steamers (20 guns); 73 brigs (73 guns); 4 screw-transports.

Unclassified.—5 steamers (5 guns); 1 monitor (3 guns); 2 despatch-boats (6 guns); 1 floating battery, 1 transport.

Revenue and Expenditure.—The annual revenue of S., estimating according to the budget of 1870—1871 as a basis, is £21,428,082, and the expenses are £28,-666,694, showing a deficit of £7,238,614. The public debt, according to the statement of the minister of finance, amounted in May 1873 to 7,830,150,000 pesetas = £326,256,250, or about $1,587,726,000. The floating debt was stated to be 643,700,000 pesetas = £26,820,833, or about $130,523,500.

Education.—In 1861, there were 22,060 schools, attended by 1,046,558 scholars; in 1868, the number of scholars had risen to 1,251,653. There are ten universities in S., in Madrid, Barcelona, Granada, Oviedo, Salamanca, Seville, Santiago, Valencia, Valladolid, and Zaragoza, with 58 colleges, attended by 13,881 pupils.

History.—S., the *Spania*, *Hispania*, and *Iberia* of the Greeks, and known to the Romans by the same names, was inhabited at the period at which it first receives historical mention, by a people deriving their origin from different races. It is supposed to have been originally inhabited by a distinct race called Iberians; upon whom, however, a host of Celts are supposed to have descended from the Pyrenees. In the earliest times of which we have any record, these two races had already coalesced and formed the mixed nation of the Celtiberians, who were massed chiefly in the centre of the peninsula, in the western districts of Lusitania, and on the north coasts. In the Pyrenees and along the east coast, were to be found pure Iberian tribes, while unmixed Celtic tribes occupied the north-west. In Bætica (Andalucia) there was a large admixture of the Phœnician element, and on the south and east coasts, numerous Phœnician, Carthaginian, Rhodian, and other colonies. A portion of the south coast, called Tartessus by the Greeks, the Tarshish of Scripture, was much frequented for its mineral riches by the Phœnician merchantmen, and the 'ships of Tarshish' were as distinct a section of the Tyrian mercantile marine, as were the Spanish galleons of the 16th c., or our own Indiamen of more recent times. But the bond which connected the Iberians and the Phœnicians was purely of a commercial character. About the middle of the 3d c. B.C., the Carthaginian influence began to be much felt in Iberia, and a considerable tract of territory was brought under subjection to Carthage by Hamilcar (q. v.), who founded the city of Barcelona. During the next eight years, the Carthaginian interest was advanced, and its power further strengthened by Hasdrubal (q. v. — died 220 B.C.), son-in-law of Hamilcar, who founded Carthago Nova (the modern Cartagena), and concluded a treaty with the Romans whereby it was stipulated that he should not advance his standards north of the Iberus (Ebro). Hannibal (q. v.), son of Hamilcar, and the greatest of all the Carthaginian generals, now assumed the command in the peninsula. He attacked and destroyed Saguntum (q. v.), and thus violated the treaty made between his father and the Romans. The destruction of Saguntum was the cause of the Second Punic War, for the principal incidents of which see CARTHAGE, ROME, HANNIBAL, and the SCIPIOS. After the Romans had driven the Carthaginians from the peninsula in 206 B. C., the country was erected into a Roman province, consisting of two political divisions—*Hispania Citerior* (Hither S.) including the eastern and northern districts, or those nearest to the centre of the Roman Empire; and *Hispania Ulterior* (Further S.) including the districts furthest from Rome, or the southern and western districts. It was not, however, till 25 B.C. that the Cantabri and Astures in the extreme north of the country, laid down their arms to Augustus. After the country had been reduced to subjection, it was divided into the three provinces of Tarraconensis (embracing the northern and eastern provinces), Bætica (Andalucia), and Lusitania (Portugal and certain of the western provinces). This division of the country lasted till the reign of Constantine the Great (q. v.), (306—337). From the time of the complete supremacy of the Romans till the death of Constantine, the condition of S. was eminently prosperous. The inhabitants, when brought under the iron rule of the empire, were forced for the time to desist from the intestine wars in which it had been their habit to indulge, and adopting the language, laws, and manners of their conquerors, they devoted themselves to industrial pursuits, and increased remarkably both in wealth and in numbers. Everywhere throughout the country, towns of a purely Roman character sprang up, among the chief of which were Leon, Emerita Augusta (Merida), Pax Julia (Beja), Cæsar Augusta (Zaragoza); and numerous aqueducts, bridges, amphitheatres, &c., were built, the ruins of which are the wonder of the modern traveller. S., though obtained at enormous cost both in treasure and in human life, was for three centuries the richest province of the Roman Empire. Its fertile fields formed for a considerable time the granary of Rome, and from its metal-veined sierras, an immense amount of treasure in gold, silver, &c., flowed into the Roman coffers. 'Twenty thousand pound-weight of gold,' says Gibbon, 'was annually received from the provinces of Austria (Asturias), Galicia, and Lusitania.' This amount of wealth was not the voluntary offering of the natives, who were compelled to labour in their mines for the benefit of strangers; and thus S., in the early ages, was the type of Spanish America in the 15th and succeeding centuries, with the single difference that in the first case the Spaniards were the slaves, and in the second they were the slaveholders. In 409 A. D., hordes of barbarians, Alans, Vandals, and Suevi, crossed the Pyrenees and swept over and desolated the peninsula—the Vandals for the most part settling in Bætica, the Alans

in Lusitania, and the Suevi in Leon and Castile. About 412, the Visigoths invaded the country, and their king, Athaulf, who acknowledged a nominal dependence on the Roman emperor, established the Gothic monarchy in Catalonia. See GOTHS. Of the Visigoths—by whom the Suevi were subjugated (584), the Vandals and Alans expelled (427) from the country, and large portions of Gaul annexed to their Spanish dominion—the most remarkable kings were Wallia (415—418), who greatly extended the Gothic monarchy; Euric (466—483), who, besides increasing his territory, introduced and enforced a body of laws, and did much for the advancement of civilisation in S.; Wamba (673—680), who built a fleet for the protection of the coasts; and Roderic (q. v.), who was killed at Xeres de la Frontera in 711, in battle with the Moors. The battle of Xeres gave the Moors almost undisputed mastery of nearly the whole of S., as well as of the outlying Gothic province of Septimania (Languedoc) in France; for the remnant of the Goths betook themselves to the highlands of Asturias, Burgos, and Biscay, where, in a region which throughout had enjoyed more liberty than any other part of S., they maintained their independence.

Dynasty of the Moors.—The Arabs, or, as they are more properly termed, the Moors (q. v.), held S. for the first few years of their rule, as a dependency of the province of North Africa; but, after the downfall of Muza (q. v.), and his son Abd-el-aziz, who had been the deputy-governor of Spain, the country was governed (717) by *emirs* appointed by the calif of Damascus. The favourite scheme pursued by the Spanish emirs was the extension of their conquests into Gaul, to the neglect of the rising power of the Goths in Asturias; they also took the Balearic Islands, Sardinia, Corsica, and part of Apulia and Calabria; the Mediterranean was infested by their fleets, but their northward progress was most signally checked on the plain of Tours by Charles Martel (q. v.). Anarchy and bloodshed were prominent features of the first 40 years of Mohammedan rule in Spain. The *walis*, or local governors of districts and provinces, frequently rebelled against the emir, and drew sword against each other according as ambition or animosity dictated. Within this period of 40 years, no fewer than 20 emirs had been called to the direction of affairs; but a revolution at Damascus, which unseated the Ommiades, and placed the Abbasides in possession of the califate, put an end to this state of misrule in S. The last of the *emirs*, Jussuf, was in favour of the Abbasides, but the *walis* and *alcaydes* being chiefly of the Ommiade faction, invited one of this family, who was in concealment among the Zeneta Arabs in Barbary, to become an independent calif in Spain. See OMMIADES. Thus was founded the *califate of Cordova*, from which, in 778, the Franks wrested all its possessions north of the Pyrenees, and North-eastern S. to the Ebro; the latter acquisition, subsequently denominated the *Spanish March*, being alternately in the hands of the Moors and dependent upon France.

Christian Kingdoms.—During this period of Moorish domination, the small independent kingdom of Asturias, founded by Pelayo (q. v.), had been growing in power and extent. It was increased by Galicia in 758, and by parts of Leon and Castile towards the close of the century. In 758, a second independent Christian kingdom was founded in Sobrarve, and increased by portions of Navarre on one hand and Aragon on the other, but though it, along with the French Gascons, aided the Moors at Roncesvalles (q. v.), it was, in 801, again swallowed up by the califate of Cordova. However, 36 years afterwards a Navarrese count, casting off his allegiance to France, founded the third Christian kingdom, that of Navarre (q. v.), which from this time easily maintained itself, owing to its situation, in independence of the Moors. The kingdom of Asturias, now (900) Leon, was for a long time distracted by bitter and bloody strife among the members of the royal line, and with its neighbour Navarre would have fallen an easy prey to the powerful Ommiades, had not the latter directed their chief attention to the subjugation of Morocco; and under cover of this relaxation of the constant warfare between Moors and Christians, another independent monarchy, an offshoot from Leon, was founded in Castile (933, kingdom in 1035), which, from its central position, and consequent greater facilities for expansion, soon became the most powerful of the Spanish states, especially after its union (temporary, 1072—1157), in 1230, with Leon. A considerable part of Aragon had been wrested from the Moors by Sancho III. (1000—1035) of Navarre, and at his death this part of his dominions passed by inheritance to his son Ramiro, who added to it the districts of Sobrarve and Ribagorza, and a considerable extent of country which he conquered from the common enemy, the Moors. This kingdom of Aragon was the last Christian kingdom formed in S.; and though it increased by acquisitions from the Moors, yet being limited by Leon, Castile, and Navarre on one side, and the Spanish March (now only the county of Catalonia or Barcelona) on the other, its princes aimed at maritime power; and by the union, through the marriage of the Count of Barcelona with Queen Petronilla, of the Spanish March with Aragon, means were obtained of carrying out this policy, and the spread of the Aragonese dominion to Sicily (q. v.), Naples (q. v.), and other regions bordering on the Mediterranean, was the consequence. These three kingdoms—Castile and Leon, Navarre, and Aragon—continued, sometimes in combination and sometimes separately, to war against their common enemy, the Moors—Castile being, from its greater power and proximity, the most persistent assailant, and Navarre, for the opposite reason, the least so; but whenever the arrival of fresh levies from Africa, or the accession of an energetic calif threatened serious danger to any one of the three, the others generally came to its aid.

The extinction of the Ommiades in Spain in 1031, and the disruption of the califate into the minor kingdoms of Cordova, Seville, Toledo, Lisbon, Zaragoza, Tortosa, Valencia, Murcia, Badajos, and seven others of less note, was an occurrence by which the kings of Castile and Aragon did not fail to benefit, for by well-directed and unremitting attacks they subdued some, rendered others tributary, the kings of Portugal also on their side gallantly and successfully pursuing the same policy; and a few years more would have certainly annihilated Moorish domination in S., had not Mohammed of Cordova and Seville, hard pressed by Alfonso VI. of Leon and Castile about the close of the 11th c., applied for aid to an Arab tribe, whose military career in North Africa had been of the most brilliant character. This tribe, the Almoravides—i. e., men devoted to the service of God—had made themselves masters of the provinces of Africa and Almagreb, and founded the empire of Morocco. Responding to the request of Mohammed, the Almoravides crossed over to S., defeated the king of Aragon and Castile, and recovered much of New Castile. Then, turning upon their ally Mohammed, they compelled him to yield up the provinces of Cordova and Seville, and all the minor Moorish princes to follow his example; so that, in 1094, the Almoravide sovereign was acknowledged sole

monarch of Mohammedan Spain. The power of this tribe, however, began to decline about 1130, and was extinguished by the Almohades (q. v.), a fanatical sect of Mohammedans, who landed in S. in the middle of the 12th c., and conquered the territories of the Mohammedans in Spain. During the reign of the third monarch of this dynasty took place the battle between the combined forces of Castile, Leon, Navarre, Aragon, and Portugal, with the Moors, in which the former gained the most celebrated victory ever obtained by the Christians over their Moslem foes, the latter losing, according to the account transmitted to the pope, 100,000 killed and 50,000 prisoners. This sanguinary conflict, fought on the plains of Tolosa (*las navas de Tolosa*), 16th July 1212, broke the Almohade power in Spain, as that of Salamanca (22d July 1812), almost exactly six centuries afterwards, did the more formidable strength of Napoleon. On the fall of the Almohades, Mohammed-ben-Alhamar, the king of Jaen, rose to the first place among the Mohammedan princes, and founded (1238) the *kingdom of Granada*. The king of Granada was speedily forced to become a vassal of Castile, and from this period all danger from Moslem power was over. The rest of the history of the Spanish kingdoms before their union is undeserving of a detailed account. The Castilian court was the scene of almost constant domestic strifes and rebellions, varied with a campaign against Granada or in favour of the monarch of that kingdom against his rebellious vassals; the only prominent monarchs of this kingdom being Ferdinand III., who confined the Moorish dominion to the south of Andalucia, Alfonso X. (q. v.), Alfonso XI., Pedro the Cruel (q. v.), and Queen Isabella, the last sovereign of Castile, who succeeded her brother Henry IV., owing to a wide-spread belief in the illegitimacy of the latter's daughter. Aragon, on the other hand, was almost wholly free from intestine dissensions, doubtless owing to the interest taken by the Aragonese monarchs in Italian politics; of these sovereigns Jayme I. (1213—1248) conquered Valencia and Majorca, and, first of all the Aragonese kings, received a voluntary oath of allegiance from his subjects; Pedro III. (1248—1285), who obtained Sicily (1282), Minorca, and Iviza; Jayme II., who conquered Sardinia and Corsica; Alfonso V. (1416—1468), who conquered Naples; and Ferdinand II. (q. v.), the Catholic, the last sovereign of Aragon, who, by marriage with Isabella, Queen of Castile, in 1469, the conquest of Granada in 1492, and that of Navarre in 1512, united the whole of Spain (and French Navarre) under one rule.

The year 1492, in the reign of Ferdinand and Isabella, witnessed also the discovery of America, as well as the capture of Granada. S. had now become consolidated into one empire, from the Pyrenees to the Strait of Gibraltar; civil wars were at an end; and a splendid continent, teeming with riches, had been opened up for Spanish adventure and enterprise. But, as the most active spirits among the Spaniards now crowded to the New World, the soil of S., and its mineral treasures, both inexhaustible sources of wealth, were neglected for the riches of the fancied El Dorado, where, as was everywhere believed, gold was more plentiful than iron was in the old country. Besides the drain upon the country from emigration, the expulsion of the Jews and Moors was productive of the direst results; and the decline of the splendid Spanish Empire, upon which the sun even then never set, may be said to have had its origin in the event which raised the country to the height of its magnificence. Charles I. (Charles V. of Germany, q. v.) succeeded Ferdinand, and in his reign Mexico (q. v.) and Peru (q. v.) were added to the possessions of Spain. Philip II. (q. v.), by his enormous war expenditure and mal-administration, laid a sure foundation for the decline of the country. Industry, commerce, and agriculture may be said to have been extinguished at the expulsion of the Moriscoes (see MOORS); and the reigns of Philip III. and Philip IV. witnessed a fearful acceleration in the decline of S. by the contests with the Dutch, and with the German Protestants in the Thirty Years' War, the intermeddling of Olivarez (q. v.) in the affairs of Northern Italy, the rebellion of the Catalans, whom the minister wished to deprive of their liberties, the wars with France, and the rebellion of Portugal (1640), which had been united to S. by Philip II. That of Charles II. was still more unfortunate, and the death of the latter was the occasion of the War of the Spanish Succession (see SUCCESSION, WAR OF). Philip V. (q. v.) was the first of the Bourbon dynasty who occupied the throne of Spain. Under Charles III. (1759—1788), a wise and enlightened prince, the second great revival of the country commenced; and trade and commerce began to shew signs of returning activity. During the inglorious reign of Charles IV. (1788—1808) who left the management of affairs in the hands of the incapable Godoy (see ALCUDIA), a war (1796—1802) broke out with Britain, which was productive of nothing but disaster to the Spaniards, and by the pressure of the French another arose in 1804, and was attended with similar ill success. Charles abdicated in favour of his eldest son, the Prince of Asturias, who ascended the throne as Ferdinand VII. Forced by Napoleon to resign all claims to the Spanish crown, Ferdinand became a prisoner of the French in the year of his accession, and in the same year Joseph, the brother of the French emperor, was declared king of S. and the Indies, and set out for Madrid, to assume the kingdom thus assigned to him. But before this time, an armed resistance had been organised throughout the whole country. The various provinces elected juntas or councils, consisting of the most influential inhabitants of the respective neighbourhoods, and it was the business of these juntas to administer the government, raise troops, appoint officers, &c. The supreme junta, that of Seville, declared war against Napoleon and France on the 6th of June 1808. In July, England, on solicitation, made peace with S., recognised Ferdinand VII. as king, and sent an army to aid the Spanish insurrection. Joseph, on July 9, entered S., defeated (through his lieutenant Bessières) the Spaniards at Rio Seco, and entered Madrid on the 20th; but the defeat of Dupont at Baylen by the veteran Spanish general Castaños, somewhat altered the position of affairs, and Joseph, after a residence of ten days in his capital, was compelled to evacuate it, and retire north to Vitoria. The noble defence by Palafox of the city of Zaragoza against Lefebvre, and the return of the Marquis de la Romana with 7000 regular troops who had been wiled from the country by Napoleon, did much to inspirit the patriots. On the 12th July 1808, Sir Arthur Wellesley, afterwards Duke of Wellington (q. v.), at the head of the British auxiliary force, landed (5th August) at Mondego Bay, and began the Peninsular War by defeating the French at Roliza and Vimiero (q. v.); but in spite of his opposition, the Convention of Cintra was signed, and the French transported to their own country. In November 1808, Napoleon, who had been preceded by Ney (q. v.) with 100,000 men, entered S., and at once assumed the command. For a time his armies were completely successful; Soult utterly routed the Spanish general Belvedere, 10th November, and annihilated Blake at Reynosa on the 13th. Castaños and Palafox were routed at Tudela by Lannes, and in the

beginning of December, Napoleon entered Madrid. At this time, the British forces were under the command of Sir John Moore (q. v.), who, aware of his great inferiority in numbers and resources, retreated west from Salamanca, whither he had come to assume the command of the allied forces, and reached Coruña (q. v.) on the 11th January 1809. On the 22d April, General Wellesley arrived in Portugal, and, at once commencing operations, drove Soult from Oporto, and took possession of Portugal; then, favoured by the disunity of action which subsisted between the three or four French armies who held S., he directed his attacks upon the army of the centre, retreating when any of the others came to its aid, and by dint of masterly generalship and bold enterprise, succeeded, after four campaigns, in driving the French from the country. To this result, the co-operation of the Portuguese and of the Spanish *guerrillas*, the revengeful hatred of the peasantry towards their tyrannical oppressors, and the drafts from the Spanish armies so frequently made by Napoleon for his wars in Central Europe, largely contributed. See WELLINGTON, SOULT, VICTOR, &c. Napoleon, loath to lose his hold of the Peninsula, sent Soult, his most trusted general, to stop the ingress of the British into France; but the battles of the Pyrenees (24th July—1st August 1813), and of the Nivelle, Orthez, and Toulouse, in the beginning of 1814, brought to a victorious conclusion this long and obstinate contest.

In 1812, a constitution, on the whole liberal, had been devised for the country by the Cortes of Cadiz. It was abrogated, however, by Ferdinand VII. (q. v.), who treated the subjects who had shewn such devoted loyalty to him with infamous ingratitude, and obtained the aid of France to establish despotism. The reign of his daughter, Isabella II. was disturbed by the Carlist rebellion in 1834—1839, in which the British aided the queen with an army under Sir De Lacy Evans. See CARLOS. The next events of importance were the contest between Espartero (q. v.), the regent, and the Queen-dowager Christina, for the supreme power during the minority of the queen; Espartero's flight before O'Donnell and Narvaez (1843); his restoration in 1847; banishment of Queen Christina (1854); formation of the O'Donnell ministry (1858;) war with Morocco (q. v.), and annexation of St Domingo (1861),—acknowledged independent in 1865; war with Peru and Chili (1864–65), and permanent truce in 1871; insurrection under General Prim (1867), soon suppressed; flight of Queen Isabella (Sept. 1868), and eventual abdication, and formation of a provisional government, with Serrano as President and Prim minister of war. Protestant worship was permitted (Jan. 1869), and Bibles admitted April the same year. On the 10th of June 1869, a constitution was adopted providing for a senate and congress and a monarchical form of government. After much search for a king, the choice fell upon the Duke of Aosta, second son of Victor Emanuel, and he was declared sovereign on November 16, 1870, under the title of Amadeo I. He was succeeded by Alfonso XII. (son of Queen Isabella), who was proclaimed king December 31, 1874. The present constitution was adopted in 1876, and provides that Spain shall be a constitutional monarchy.

SPALA'TO (often erroneously called SPALATRO; in Illyric, SPLIT), an important seaport of Dalmatia, empire of Austria, is finely situated on a promontory projecting into one of those numerous bays that mark the eastern coast of the Adriatic. It originated in the famous palace of Diocletian, built in the 3d century. As this immense structure (which occupied twelve years in building) stood not far from the city of Salonæ, the great bulwark of Roman power in Dalmatia, it was called *Salonæ Palatium*, briefly written *S. Palatium*. When Salonæ was conquered by the Avars in the 7th c., the inhabitants fled for refuge to the fortress-palace of the emperor, where they laid the foundations of a new town, corruptly named *Aspalathum*, whence the modern *Spalato*. Even yet, more than one-half of the town is compressed within the limits of the ancient palace, a considerable portion of whose walls still remain. The best-preserved parts of the palace are the temple of Jupiter, transformed in the 7th c. into a Christian cathedral, and the temple of Æsculapius, which is now a Baptistery dedicated to St John. Modern S. is divided into an old and new town; the former consisting mainly of narrow, crooked, and dirty lanes; the latter more agreeable and open. It is the seat of a bishop, has a chamber of commerce and manufactures, and is the principal emporium for goods passing from Italy overland into Turkey. Pop. 15,784.

SPA'LAX. See MOLE-RAT.

SPA'LDING, an important market-town and river-port in Lincolnshire, in a rich agricultural district, on the Welland, 8 miles from its mouth in the Wash. Considerable trade is carried on by the Welland, and vessels of 100 tons are able to reach the town. The grammar-school, founded in 1568, has £174 a year from endowment. An important stock and corn market is held every Tuesday. S. was a place of consequence as early as the Saxon times, and contained a Benedictine monastery. Pop. (1881) 9260.

SPALLANZANI, LAZARO, a celebrated anatomist and naturalist, was born at Scandiano, in Modena, Italy, 12th January 1729. After a careful education, he took clerical orders; and in 1754, he was appointed to the chair of Logic, Metaphysics, and Greek at Reggio; but soon after this he obtained a chair at Modena, and refusing the tempting offers made him by the universities of Parma and Coimbra, and the Academy of St Petersburg, gave himself up to the study of natural history. His attention was directed to the doctrine of generation propounded by Needham and Buffon, which, after careful study and experiment, he overturned. He then turned his attention to the circulation of the blood, and was the first to follow its course through the intestinal tube, the liver, spleen, ventricles, pulmonary organs, &c.; 'established,' according to Senebier, 'the propulsive power of the heart over the blood in the various vessels, demonstrated that the heart never wholly empties itself, explained the various causes which retard the circulation, and the obstacles produced by the weight of the blood.' On the re-establishment of the university of Pavia, S. was appointed (1768) Professor of Natural History, and keeper of the museum, which he greatly enriched with fishes, crustacea, and testacea, the fruits of his numerous excursions. In 1785, refusing the chair of Natural History at Padua, which had been so admirably filled by Vallisnieri, he accepted the proposal of the Archduke Ferdinand to accompany, with doubled salary, the Austrian ambassador to Constantinople (22d August 1785); and during a residence of 11 months in Turkey, found ample materials for study and observation. In 1788, he visited Naples whilst Vesuvius was in eruption, the Lipari Isles, and Sicily, in restless prosecution of his scientific labours, and then retired to Pavia, where, refusing the tempting offers of the French Directory, he spent the remainder of his life, prosecuting his scientific researches amid bodily sufferings, and died of apoplexy, 12th February 1799. His works, many of the more valuable of which have been translated into English, are too

numerous to mention; but a complete catalogue of them, along with a biography, will be found in the *Biographie Médicale*, vol. vii. See also, for the result of his labours, the *Eloge*, by M. Alibert, in the *Mémoires de la Société Médicale d'Emulation*.

SPAN, a natural measure of length, being the distance between the tips of the thumb and middle finger, the hand being stretched as much as possible. This space averages about 9 inches, and the term came to denote a measure of 9 inches.

SPA'NCELLED, in Heraldry, a term applied to a horse two of whose legs are fettered by a log of wood.

SPA'NDAU, a town of Prussia, in the province of Brandenburg, is situated at the confluence of the Havel and Spree, 9 miles west-north-west of Berlin. S. is a fortress of the third rank; has a citadel (used as a state-prison) surrounded by water, with a garrison of 2000 men, and is a military dépôt. S. carries on manufactures of arms, gunpowder, woollens, &c., and has an active transit-trade as a station on the Berlin and Hamburg Railway. Pop. 17,306. It is one of the oldest towns in the Middle Mark of Brandenburg, and was long the residence of the Kurfürsts of the Hohenzollern House.

SPA'NDREL, the triangular space between the outside of an arch and a square head including it. This space is often filled with sculptured foliage, figures, &c.

SPA'NGLES, small circular pieces of very thin metal, usually silvered or gilded tin, pierced with a needle-hole, so that they can be sewed on to cloth. They are chiefly used for decorating theatrical dresses.

SPA'NIEL, a kind of dog, of which there are many breeds, differing considerably in size and other characters. None of the spaniels are large; some are amongst the smallest of dogs. Some are used for sporting purposes, others are merely kept as pets and companions. All of them are lively, playful, docile, and affectionate in a high degree. The S. is ever petitioning for regard, and shews boundless joy on receiving marks of kind attention. The ENGLISH S. is of an elegant but moderately stout form; with very large pendent ears, of which the hair is very long; the muzzle rather broad; the tail bushy; the body covered with long silky hair; the colours various, very often liver-coloured and white, or red and white. The name S. is said to indicate the introduction of this kind of dog into England from Spain. In the days of falconry, spaniels were much used for starting the game. The Cocker (q. v.), the Springer (q. v.), and the Blenheim Dog (q. v.) are nearly allied to the S., and are sometimes called by that name. The KING CHARLES'S S. is a beautiful black and white breed, almost as small as the Blenheim dog, and derives its name from Charles II., who took great delight in dogs of this kind. The WATER S. is one of the larger breeds. It has comparatively hard hair, and is distinguished by its readiness to pursue game by swimming. It is much used in decoy-ponds to drive ducks into the net.

SPANISH GRASS. See PAPER.

SPA'NISH LANGUAGE AND LITERATURE. The Spanish language is one of the Romanic tongues, and, like the others, originated in the *lingua Romana rustica*. See ROMANIC LANGUAGES. The earliest of the different Spanish dialects that assumed a literary form was the Castilian, which gradually became, and has continued to be, the classic dialect of the nation. It finely blends a certain soft, lingering richness of cadence, with an occasional sonorous majesty of expression, and on the whole may be considered one of the most beautiful of the European tongues. The course of Spanish conquest has also led to its establishment in Mexico, Central America, Cuba, Porto Rico, the greater part of South America, the Canary Isles and the Philippines. See the *Grammar and Dictionary* published by the Spanish Academy (1771), the grammars of Kiel (Leip. 1837), Fuchs (Berl. 1837), Wiggers, and Schele de Vere (New York, 1854). The best material for a historical grammar is furnished by Diez in his *Grammatik der Romanischen Sprachen*. The best Spanish dictionaries, besides that of the Academy, are Cabrera's (Mad. 1837), the Spanish-German by Seckendorff (3 vols., Hamb. 1823), and the Spanish-English of Neuman and Baretti (re-edited by Velazquez, New York, 1852).

Literature.—The literature of Spain may, in a superficial sense, be regarded as commencing under the auspices of the Romans, for Lucan, Seneca, and other eminent Latin authors were at least Spanish by birth; and, if we please, we may further look upon the Christian ecclesiastical writers of the Gothic period as the second link in the historical chain. But in the proper sense of the term, the literature of these two periods is no more *Spanish*—i. e., national—than an English book by an Anglo-Indian is to be held as a portion of Hindu literature, or the sermons preached by a missionary to South Sea Islanders are to be quoted as specimens of the literature of the Pacific. Passing over, then, the various developments of non-national literature in Spain—pagan Latin, ecclesiastical Latin, Arabic and Jewish—we come down to the 12th c., and then, for the first time after the gradual formation of a Spanish language, begin to notice the growth of something like a Spanish literature. Epic and didactic poems appear, written in Castilian verse, and full of strong national sentiment. The oldest of these is the *Poema del Cid* (see CID CAMPEADOR), of which only a single MS. exists. This MS. contains three other poems: *The Book of Apollonius, Prince of Tyre; The Life of Our Lady, St Mary of Egypt;* and *The Adoration of the Three Holy Kings*, the authorship of which (as of the *Poema del Cid*) is unknown. Other productions of this *first* period are the rhymed *Lives of the Saints*, by Gonzalo of Berceo (died about 1260); and the anonymous poem, *Count Fernan Gonzalez*, which, like the *Poema del Cid*, paints the earnest and picturesque struggle between the Moors and Spaniards. In all of these, we trace the influence either of the church or of the chivalric poetry of France; but they maintain, nevertheless, a distinctively national and independent character. A great impulse was given to the artistic development of Spanish literature by Alfonso the Wise of Castile (q. v.), who substituted Spanish for Latin in the courts of law, and fostered in many ways the growth of the national language. He is regarded as the founder of Spanish prose, his chief work in this department being the compilation of a series of codes, of which the most memorable is *Las Siete Partidas*, and a translation of the Bible into Spanish. Subsequent princes walked in his steps, and achieved an honourable reputation both as authors and patrons of literature, conspicuous among whom was the Infante Don Juan Manuel (died 1347), whose *El Conde Lucanor* (Count Lucanor) is a collection of 49 tales, apologues, &c., from oriental sources, and wearing an oriental aspect. The most remarkable Spanish poet of the 14th c. is Juan Ruiz, arch-priest of Hita (died 1351). His pieces, composed in a great variety of measures, number some 7000 verses, and include religious and love songs, fables, pastorals, &c. The didactic

tendency is particularly visible in the *Danza general de la Muerte* (Dance of Death).

The *second* period of Spanish literature embraces the later portion of the middle ages, and is marked by the presence of lyric poetry in considerable quantity, alongside of the didactic. It seems to have been inspired by the strains of the Provençal poets settled at the court of the Counts of Barcelona, and always continued to be more courtly than national. The most complete collection of this lyric poetry is the *Cancionero general* of Fernando del Castillo (Valencia, 1511; 10th edit., 1573), which contains the names of 136 authors, among which may be mentioned those of the Marquis of Villena, and the Marquis of Santillana, the three Manriques, Macias, Sanchez de Badajoz, Alonso de Cartagena, Diego de San Pedro, and Fernan Perez de Guzman. Against this court-poetry, however, a strong reaction took place, the national spirit reasserting itself vigorously in ballads, chronicles, romances of chivalry, and the drama. The best collection of the ballads (about 1000 in all) is to be found in the *Romancero general* (13 vols., 1605—1614); of the Chronicles (half-genuine, half-fabulous narratives of ancient Spanish heroes), the best are those of Ayala, of Juan Nuñez de Villaizan, the *Chronicle of the Cid*, and the *Chronicle of the Travels of Ruy Gonzalez de Clavijo;* of the romances of chivalry, the most celebrated is the *Amadis de Gaul*, parent of innumerable others (see AMADIS); and of the drama, among the first specimens are the pastoral plays of Juan de la Enzina, and the *Celestina* of Fernando de Rojas.

The *third* period, extending from the 16th to the 18th c., is the most splendid and productive in the annals of Spanish literature. Under Charles V., Spain became the foremost state in Europe, and the conquest of Naples brought it into close relation with the literature of Italy. The great Italian masters, such as Dante and Petrarch, began to be studied, and Italian measures and poetic forms to be imitated, although the rich, strong, Spanish spirit is never lost. The first of this new school was Juan Boscan Almogaver (died 1543), a brilliant sonneteer; other members of the same school are Garcilaso (q. v.) de la Vega, Diego Hurtado de Mendoza (q. v.), Francisco de Saa de Miranda, and Jorge de Montemayor (author of the once famous pastoral novel of *Diana*, see NOVELS), Fernando de Herrera (q. v.), and Luiz de Leon (died 1591), the last two of whom rank as the two greatest lyric poets that Spain ever produced. Gradually, a national drama established itself too. Conspicuous names in this department are Villalobos, Perez de Oliva, and Naharro (about 1517), sometimes regarded as the father of the Spanish drama. The last-mentioned wrote his comedies in the favourite national measure, the *redondillas*, and divided them into three acts. Besides these, we must mention Lope de Rueda, Juan de la Cueva, and Geronimo Bermudez, who cultivated tragedy with success. Among the most eminent prose writers of the first section of this third period was Geronimo Zurita, author of *Annales de la Corona de Aragon* (Annals of the Crown of Aragon, 6 vols.)—a somewhat critical work, shewing a decided advance on the credulous chronicles of the monks; Oliva, whose *Dialogo de la Dignidad del Hombre* (Dialogue on the Dignity of Man) is a fine specimen of elegant literature; and Morales, author of *Discursos* (Essays), relating to practical philosophy; &c.—Cervantes (q. v.) marks, if not exactly a new era, at least a splendid outburst of Spanish genius. It is unnecessary here to criticise the productions of his genius; we may only note, as it were, historically the fact, that his immortal *Don Quixote* put an end to the romances of chivalry —or rather to the extravagant imitations of these that sprung up after the age of chivalry had passed away. Lope de Vega (q. v.), a contemporary of Cervantes, and Calderon (q. v.), gave the national drama a European renown, and had, especially the latter, a host of followers more or less celebrated, among whom are Francisco de Rojas, Agustin Moreto, Fragoso, Diamante, Antonio Hurtado de Mendoza, Juan de la Hoz, Antonio de Solis, and Agustin de Salazar y Torres. The lyric and 'epic' poets of this period, which embraces the second half of the 16th, and the whole of the 17th c., are innumerable, but not great. The most notable names are those of the brothers Argensola, and Alonso de Ercilla y Zuñiga (author of *Araucana*, a fine poem on the conquest of Araucania in Chili by the Spaniards). A peculiar form of the novel also appeared, called the 'rogues' novel,' of which the only memorable specimen is the *Guzman de Alfarache* of Mateo Aleman; and even it derives not a little of its importance from the fact that it suggested Le Sage's *Gil Blas*. In history, the most distinguished names are those of Mariana (q. v.) and Solis.

The *fourth* period of Spanish literature extends from the accession of the Bourbons (1701) to the present time, and was long marked (like the contemporary literature of Germany) by a servile imitation of French models, and these by no means the best of their kind. This literary ascendency of France in the first half of the 18th c. over all civilised Europe is a very curious phenomenon, worthy of closer study than it has yet received. The most notable of the Frenchified Spaniards was Ignacio de Luzan, whose *Poetica* (1737) is a thoroughly Gallican performance. His efforts to denationalise the literature of Spain were combated by Garcia de la Huerto and others, and at length a sort of compromise was effected, and the 'Salamanca School' emerged into notice. Its founder, Melendez Valdez (born 1754), was a man of high genius, who subordinated his liberal culture to the sovereign control of a patriotic inspiration, and the same qualities are visible in its other members—Iglesias, Noroña, Quintana (q. v.), Cienfuegos, Arriaza, and Gallego. The great Peninsular War, and the subsequent political movements in Spain had a powerful effect in stirring up anew the elements of nationality, and the present century can shew a lengthened list of names both in prose and poetry. We can only afford space for a few: Tapia, Maury, Juan Bautista Alonso, Jacinto de Salas y Quiroga, Espronceda, Serafin Calderon, Zorrilla, Hartzenbusch, R. de Campoamer, Santos Lopez Pelegrin, Villergos, and G. Gomez de Avellaneda, in poetry; Saavedra, Mora, Zorrilla Gregorio Romero y Larrañaga, Manuel de Santa Ana, in romantic fiction; Leandro, Fernandez Moratin, in the drama; Ulloa, Muñoz, Capmany, Ferreras, Quintana, Navarrete, Clemencin, Torreno, and Maldonado, in history; Jovellanos, Arguelles, Miñano, Marina, Donoso Cortes, Martinez de la Rosa, &c., in political oratory.

Spain has not as yet achieved great results in any departments of science, either physical, mental, or moral; but of late years she has turned her attention seriously to scientific studies, and several admirable treatises in jurisprudence, political economy, medicine, philosophy, philology, and geography have been produced.—See Bouterwek's and Sismondi's *Histories of Spanish Literature;* and above all, Ticknor's work on the same subject, which has been translated into Spanish.

SPANISH MAIN. See SUPPLEMENT in Vol. X.

SPA'NISH TOWN, the seat of government of the British possession of Jamaica (q. v.), on the right bank of the Cobre, and 10 miles west of

Kingston. It contains several important public institutions, is ill-built and unhealthy, and contains about 6000 inhabitants.

SPA'NKER, a large quadrilateral sail, with parallel sides, set between the gaff and boom of a ship. Its foreleech is attached by rings to the mast. The spanker is a fore-and-aft sail of great importance in bringing the vessel to the wind.

SPAR (Ger. *Spath*), a term used by miners to denote any bright crystalline mineral, and which has been adopted by mineralogists in the names of a number of minerals, as calcareous spar, fluor spar, &c., in which, however, it has no proper generic significance.

SPA'RIDÆ, a family of acanthopterous fishes, having a general resemblance to the perch family —a single dorsal fin, which is not protected by any scales, and of which the anterior rays are spinous, the pectoral and ventral fins sharp-pointed, the tail-fin notched; the gill-cover shining, without proper spines or denticulations; the palate destitute of teeth; the scales large, broader than long, and generally thin. There are several sections of the family, distinguished by the teeth, which in some are all small and card-like, whilst others have trenchant, conical, and round molar teeth, variously arranged. The greater number inhabit the seas of the warm parts of the world; many species are found in the Mediterranean; a few on the coasts of Britain. Among the British species are the Gilthead (q. v.), and several species of different genera, known by the common name of Sea Bream (q. v.). The S. are generally good for food, and some are highly esteemed. Among them are the *Sargus* of the Mediterranean (*Sargus Rondeletii*), much valued by the ancient Romans, and the Sheep's Head (*Sargus ovis*) of the North American seas, which commands a very high price in the New York market.

SPARKS, JARED, American historian, was born at Willington, Connecticut, May 10, 1789; graduated at Harvard University in 1815; became tutor in mathematics and natural philosophy, and one of the conductors of the *North American Review.* In 1819, he was settled as a Unitarian minister at Baltimore, when he wrote *Letters on the Ministry, Ritual, and Doctrines of the Protestant Episcopal Church.* In 1821, he established a periodical called the *Unitarian Miscellany and Church Monitor*, in which he first published his *Letters on the Comparative Moral Tendencies of the Trinitarian and Unitarian Doctrines.* In 1823, he edited six volumes of essays and tracts on theological subjects, and, abandoning the pulpit, became for seven years sole editor of the *North American Review.* In 1828, he published a *Life of John Ledyard, the American Traveller;* and from 1834 to 1837, edited at Boston 12 octavo volumes of the *Writings of George Washington.* This important national work was followed by the *Diplomatic Correspondence of the American Revolution* (12 vols. 8vo, Bost. 1829—1830), and the *Life of Gouverneur Morris* (3 vols. 8vo, Bost. 1832). At this period, he commenced the *American Almanac of Useful Knowledge*, and began also his *Library of American Biography*, first issued in two series of 10 and 18 vols. 18mo. In 1840 was published his collection of the *Works of Benjamin Franklin* (10 vols. 8vo), after which he visited Europe to collect materials for his *Correspondence of the American Revolution* (4 vols. 8vo, 1854). He also wrote, in 1852, two pamphlets in answer to Lord Mahon, on the *Life of Washington.* Besides these multifarious literary labours, combining laborious research with clear arrangement, a simple style and accurate statement he filled, from 1839 to 1849, the M'Lean chair of history, and from 1849 to 1852, that of President of Harvard University. In 1857 he visited Europe. Died at Cambridge March 14, 1866.

SPA'RROW (*Passer* or *Pyrgita*), a genus of birds of the family *Fringillidæ*, having a strong conical bill, the upper mandible slightly curved, the lower mandible compressed and shorter than the upper, the nostrils partly concealed by the short feathers at the base of the bill, the legs moderately long and stout, the claws sharp and curved, the tail moderately long, and nearly even at the top. The species are not very numerous, and are exclusively found in the Old World. The COMMON S., or HOUSE S. (*P. domesticus*), plentiful everywhere in the British Islands, and too well known to require description, is found also throughout Europe, abounding particularly in the northern countries, from which its range extends eastwards into Siberia, and southwards to the north of Africa and of India. Of all British birds, the S. is the boldest in its approaches to man. Town sparrows are not mere visitors from the neighbouring country, but constant inhabitants of the town itself, with the smoke of which their plumage is begrimed. The S. in its best plumage is not a very beautiful bird, nor has it such elegance of form as many others of the finch tribe; it has no melodious song, but its habits are interesting, and its frequent lively chirp pleasing. Sparrows often congregate in great flocks, particularly in autumn, when they find rich supplies of food in the ripened grain. The S. is one of the most omnivorous of birds. Animal and vegetable food seem equally acceptable to it. During summer, vast numbers of insects and their larvæ are devoured by sparrows, and in this way they make amends for their plunder of the grain in autumn, which they begin as soon as it is sufficiently ripened, and continue as long as there are sheaves in the field. Their depredations have induced many farmers to use means for their destruction. They are good to eat, though little used for this purpose in Britain. It is otherwise in France, where all the small birds are sought after as articles of food. But the destruction of sparrows may be carried too far; and in France it has been followed by an increase of caterpillars, vastly more injurious to crops than the sparrows themselves. The S. makes a very inartificial nest, collecting a quantity of hay, or some similar material, in a hole of a wall, and lining it with feathers; sometimes, but more rarely, building a rude dome-shaped nest in the higher branches of a tree. Apart from the habitations of man, which it so much frequents, it often builds in crevices of rocks, or in cliffs on the sea-coast, or under the shelter of the nests of rooks, one rook's nest sometimes covering several nests of sparrows. Several broods are produced in succession, and the breeding season is prolonged over the whole summer, one brood succeeding another. The summer plumage of the S. is more brilliant than that of winter, and the female is of more sober plumage than the male, exhibiting indeed almost no variety of colour.—The TREE S. (*P. montanus*), the only other British species, is very similar to the Common S., but of rather smaller size. It is also a widely distributed bird, frequent over great part of the Old World. It is rarely seen in towns.—In Italy, the Common S. is rare to the south of Piedmont, and another closely allied species (*P. cisalpina*), takes its place, very similar in its habits as well as in its characters.—In America, there are numerous species of *Fringillidæ*, popularly known as sparrows, of which the WHITE-THROATED S. (*Zonotrichia albicollis*) is most nearly allied to the true sparrows. The nostrils are in a small groove, and the tail is slightly forked.—The HEDGE S. (q. v.) is a bird

very different from the true sparrows.—The name S. is popularly given in different parts of the world to many different birds, chiefly *Fringillidæ*.—The bird called S. in the English translation of the Bible is a species of thrush.

SPARROW-HAWK (*Accipiter* or *Nisus*), a genus of *Falconidæ*, ranked among the *ignoble* birds of prey (see FALCONIDÆ and FALCONRY). The bill is curved from the base, short, and compressed; its upper ridge rounded and narrow; the cutting margin of the upper mandible with a distinct festoon. The wings are short; the legs long, slender, and smooth. Only one species is British—the COMMON S. (*A. nisus*, *A.* or *N. frigillarius*), a small hawk, only about twelve inches in length, a considerable portion of the length belonging to the

Sparrow-hawk (*Accipiter nisus*).

tail. It is found in almost all parts of Britain, and in Asia as far south as Bengal, and as far east as Japan. It is not found in America. It very often makes its nest in the deserted nest of a crow. It is a bold, active bird, very destructive to poultry and pigeons. The S. has often been trained for the purposes of falconry, to take land-rails, partridges, and similar game. The S. of Australia (*A. torquatus*) is marked by a collar of numerous bars of white. Its habits are very similar to those of the European sparrow-hawk.—The American S. (*Falco sparverius*), common in most parts of the United States, is similar in size to the European S., but is rather allied to the kestrel.

SPA'RTA, anciently LACEDÆMON, the capital of Laconia, and the most famous city of Peloponnesus, occupied partly a range of low hills on the right bank of the Eurotas, and partly the intervening plain. Its appearance, even in its palmiest days, was by no means equal to its renown, for, though not destitute of handsome public buildings, the severe law ascribed to Lycurgus, that 'the doors of every (private) house should be fashioned only with the saw, and the ceiling with the axe,' exercised a cramping influence on the development of architecture and of the fine arts generally. The natural defences of the place, or, at least, of the long valley of Lacedæmon, in which S. stood, were so great, that it continued unfortified down to the Macedonian period—nearly a century after its mighty struggle with Athens for the hegemony of Greece; and, indeed, it was not regularly fortified till the time of the tyrant Nabis (195 B.C.). Previous to the Dorian conquest, the primitive Achæans of S. seem to have dwelt in four or five scattered hamlets.—These hamlets were welded into one city, so to speak, by the conquerors, and became known as town-districts. The Acropolis of S. occupied a hill in the northern part of the city, and was adorned with a temple to Athena (the tutelary goddess of S.), plated with bronze, whence it was called the Brazen House, and the goddess herself *Chalciœcus* (the Dweller in the Brazen House). On the bronze plates were beautifully sculptured various Greek myths. At the eastern base of the Acropolis stood the Agora, or Market-place, whence streets proceeded to the different quarters of the city. Here stood the public buildings of the magistrates. The Agora contained many statues. The principal street in S., called the Aphetaïs, ran south from the Agora to the southern wall, through the most level part of the city, and was lined with a long succession of monumental edifices, chiefly *heroa* and sanctuaries. Along the banks of the Eurotas stretched the *Dromos* (Race-course), in which were several *gymnasia*, with temples of the Dioscuri, of the Graces, &c., and numerous statues; and still further south lay a broader level, Platanistas, so called from the plane trees that grew there. This was the scene of those mock-contests in which the Spartan youth learned to face without fear the realities of war.

The history of S. is really the history of Laconia. *When* the four hamlets, the *Pre-Dorian* S., originated, we have no knowledge; but it cannot be doubted that their inhabitants were Achæans. It is during the rule of the Achæan princes that the events of the famous, but unhistorical, expedition against Troy, forming the subject of Homer's *Iliad*, are described as taking place. Menelaus, husband of Helen, whose flight with Paris occasioned the Trojan war, was king at S., and it was during the reign of his grandson, Tisamenus (according to the legend), that the Dorians (q. v.) invaded Peloponnesus. The *fact* of a Dorian invasion is universally admitted, but of the details, scanty even as they are, we may safely be sceptical. We cannot even be certain of the date of the event, or even of the century in which it occurred. All that is clear is, that the native Achæan population were deprived of political privileges, and appear henceforth as *Periœci* (q. v.) and Helots (q. v.)—the Dorian conquerors alone forming the historical Spartans. Towards the middle of the 8th C. B. C., the Dorians of S. had not only thoroughly established themselves in their new settlement, but had subjugated the whole of the fertile and beautiful vale of Lacedæmon, commonly known as Laconia, and had begun to cherish ambitious views of extending their supremacy over the other Dorian settlements in Peloponnesus—viz., those of Messenia and Argos. Hence originated the Messenian wars (see MESSENIA), which terminated (668 B. C.) in the complete overthrow of the Dorians of Messenia, who were reduced by the victorious Spartans to the condition of Periœci. Similar struggles occurred both with the older Achæan inhabitants in the centre of Peloponnesus and with the Dorians of Argos, &c., in which the Spartans were generally successful. The development of their warlike and ambitious character is usually ascribed to the institutions of Lycurgus (q. v.); and whatever we may think of that more than semi-mythical personage, the institutions that go under his name were well fitted to make the Spartans exactly what they figure in history—a race of stern, cruel, resolute, rude, and narrow-minded warriors, capable of a momentary self-sacrificing patriotism (as in the story of the 300 heroes who fell at Thermopylæ), but utterly destitute of the capacity for adopting or appreciating a permanently noble and wise policy.

The outbreak of the Peloponnesian war (431 B. C.) brought the rivalry between S. and Athens to a head, and in the mighty struggle that ensued, victory declared on the side of the combatant least capable of maintaining the greatness of Greece. S. now attained the hegemony of Greece; but her insolent tyranny in the hour of her triumph excited the indignation of those whom she held in virtual subjugation, and the glorious retaliations of the Thebans under Epaminondas (q. v.) stripped her of all her splendid acquisitions, and reduced the Laconian state to its primitive boundaries. Later, the rise of the Macedonian power limited still more the Spartan territory, nor did it ever after attain its earlier dimensions. Finally, after a series of vicissitudes, S. passed into the hands of the Romans, became a portion of the Roman province of Achaia, and shared the fortunes of the great republic.

SPA'RTACUS, the leader in the great insurrection of Roman slaves in Southern Italy which took place 73 B. C., and in all probability the first servile captain in point of genius of whom history preserves a record, was a native of Thrace, and originally followed the occupation of a shepherd, but afterwards became a robber-chief. Having the misfortune to be taken prisoner, he was placed in a training-school for gladiators kept by one Lentulus Batiatus, at Capua. A conspiracy to escape was formed among the gladiators (200 in all, and mostly Gauls and Thracians), the heads of which were S., and two Gauls, Crixus and Œnomaus. The conspiracy was discovered; but 70, among whom were the leaders, forced their way through the streets of Capua with cleavers and other such rude weapons as they could seize, defeated a detachment of Roman soldiers sent to bring them back, and established themselves on Mount Vesuvius, where they received considerable accessions to their number—chiefly runaway slaves. Three thousand Roman troops under C. Claudius Pulcher sought to blockade them here and starve them into surrender. S. was now chosen as their leader, with Crixus and Œnomaus for his lieutenants. Descending the hill at a place and in a way totally unexpected, he took his assailants in the rear, and inflicted on them a disgraceful defeat. His original design had been limited to securing his freedom, and making his way back to his own country, nor during the two years that the insurrection lasted did he ever forget this ultimate aim; but in order effectually to carry it out, he recognised the necessity of a far more serious and extensive warfare than had yet been waged, and proclaiming freedom to all slaves, he contrived to raise his trivial mutiny to the dignity of a servile war. Circumstances were favourable. A great portion of Italy, especially of Central and Southern Italy, had been turned into pasture-land (see ROME), and instead of villages of sturdy and independent farmers, who owned the land they tilled, gangs of discontented slaves watched the flocks and herds of great nobles, demoralised by a plethora of ill-gotten riches. It was to these slaves that S. appealed, and his summons was not in vain. Thousands upon thousands rushed to his standard, and victory followed him wherever he went. The story of his triumphs reads like a romance. No knight of chivalry was ever more uniformly successful, for a time. After defeating Claudius Pulcher, he routed and slew Cossinius, legate of Publius Varinus; then he worsted Varinus himself in several engagements, capturing his lictors and the very horse on which he rode. All the southern part of the peninsula now fell into his hands: the country was devastated, the cities either pillaged or garrisoned. But S. knew too well the enormous resources of Rome, and the extraordinary energy which she was capable of exhibiting in the hour of peril, to hope for final success, and he consequently sought to induce his victorious bands to march northward to the Alps, and disperse to their own homes, the Gauls to the west, and the Thracians to the east. But the slaves were too deeply intoxicated with their success to see the wisdom of his proposal, and S. had to continue his career of mere fighting against his better judgment, and embarrassed by the jealousies that are so apt to spring up among undisciplined and servile hordes. What brilliant gallantry and skill he shewed, is known to all readers of Roman history. After the defeat and death of his lieutenants, who had separated from him (72 B. C.), he marched north through Picenum towards the Po, overthrew first one consular army under Cn. Cornelius Lentulus and then another under Gellius Poplicola, and at the head of 100,000 men, meditated a march on Rome. Since the days of Hannibal, there had never been such danger! Fortunately, servile indecision and unwisdom saved the city. S. was forced by his followers to retreat south, and took up his winter-quarters at Thurii, where he held a great fair for the sale of the spoils of Roman cities. In 71 B. C., Crassus (q. v.) took the field against the terrible slave-leader, but for a while even he could do nothing. Near Mutina, the proconsul, C. Cassius Longinus, and the proprætor, Cn. Manlius, were defeated; in Picenum, Mummius, a legate of Crassus's, was utterly routed; at last, however, Crassus succeeded in forcing S. into the narrow peninsula of Rhegium, whence he tried to get into Sicily, with the view of rekindling the servile war that had recently raged in that island, but failed in his attempt, through the treachery of those with whom he had opened negotiations. Crassus now built lines of circumvallation to hem him in, and force him to surrender; but one stormy winter-night, S. broke out of the toils prepared for him, and resumed the offensive, although he had suffered heavily by loss and desertion, and his forces were still further diminished by the formation of an independent army of Gallic slaves, which had no sooner got a leader of its own, than it was annihilated. Near Petelia, he once more defeated his adversaries; but seeing clearly that with such wretched materials as he had he could not hold out much longer, he made a dash at Brundusium, hoping to seize the shipping in the harbours, and get safely across the Adriatic to his native shore, but was baffled by the presence of Lucullus (q. v.). Pompey, too, had returned from Spain. There was nothing left for S. but to die as gallantly as he had lived. Drawing up his army in battle-array, and solemnly slaying his war-horse, he began his last fight in a spirit of heroic desperation, and after performing prodigies of valour, fell unrecognised among the heaps of his slain foes. After his death, the slave insurrection was at an end.

SPASM (Gr. *spasma*) consists in an irregular and violent contraction of muscular parts—involuntary even when the voluntary muscles are concerned. There are two sorts of spasm. In one, there is an unusually prolonged and strong muscular contraction, not rapidly alternating as usual with relaxation, the relaxation only taking place slowly, and after some time. This is known as *tonic spasm* (Gr. *tŏnŏs*, a bracing up) or *Cramp* (q. v.). 'When in a more moderate degree affecting the voluntary muscles generally, it constitutes Catalepsy (q. v.), in which, from the muscles remaining contracted, the limbs will retain whatsoever attitude they are placed in, until the spasm is over. But the extreme example is Tetanus (q. v.), in which the spasms are so violent and so enduring, that they may be said to squeeze the patient to death.'—Williams's *Principles of Medicine*, 2d ed. p. 72. In

the other form of spasm, the contractions of the affected muscles take place repeatedly, forcibly, and in quick succession; the relaxations being, of course, equally sudden and frequent. This is named *clonic spasm* (Gr. *klŏnŏs*, an agitation), and is popularly known as *convulsions*. Chorea (or *St Vitus's dance*), epilepsy, and convulsive hysteria, afford examples of this kind of spasm.

The treatment varies according to the cause of the excessive muscular irritability. Firm pressure on muscles affected with spasm will promote their relaxation, and by strong steady pressure on the masseter muscles, the lower jaw has been depressed, so as to open the mouth, in cases of lock-jaw. The medicines which are employed to counteract irregular or inordinate muscular action are termed *antispasmodics*; but spasm may depend upon so many different causes that the remedies which are found most successful in combating it must vary extremely in their nature. There are, however, a few medicines which appear to exercise a control over spasmodic action generally. These may be termed *pure* or *true* antispasmodics. They are Asafœtida, Cotyledon umbilicus (or Common Navel-wort), Wood-soot, Galbanum, Musk, Rue, Sagapenum, Sumbul (Jatamansi or Musk Root), and Valerian. Amongst the narcotics often useful in these affections, we may especially mention Belladonna, Cannabis Indica (or Indian hemp), Opium, and Stramonium. Sulphuric ether in draught or inhaled, and inhaled chloroform, are often of service. In some cases, remedies which directly depress the vital powers, such as the prolonged use of the warm bath, or even, in rare cases, the abstraction of blood, are the most effectual means of subduing spasm.

SPATHE (*Spatha*), in Botany, a sheathing bract which encloses one or more flowers, as in the *Narcissus*. Very frequently the flowers within a spathe are arranged upon a *spadix*, which is a succulent spike, with numerous flowers, and of which a familiar example may be seen in *Arum triphyllum*. The spadix is a characteristic feature of the Palms, and in them is compound or branching, and in general is not only provided with a common spathe, but with secondary spathes at its divisions.

SPAVIN, a disease of horses, occurs under two different forms, both interfering with soundness. In young, weakly, overworked subjects, the hock-joint is sometimes distended with dark-coloured thickened synovia or joint-oil. This is bog or blood spavin. Wet bandages, occasional friction, a laxative diet, and rest, should for several weeks be diligently tried; and if such remedies prove unsuccessful, the swelling must be dressed with strong blistering ointment, or fired. The second variety of spavin is the more common and serious. Towards the inside of the hock, at the head of the shank-bone, or between some of the small bones of the hock, a bony enlargement may be seen and felt. This is bone spavin. At first, there is tenderness, heat, swelling, and considerable lameness; but as the inflammation in the bone and its investing membrane abates, the lameness is less perceptible, although the animal continues to drag his leg and go stiffly. In recent and slight cases, cold water should be applied continuously; but in serious cases, when the limb is swollen and tender, hot fomentations are best. For several days, they must be perseveringly employed. When the limb is again cool and free from pain, an iodide of mercury or fly-blister should be applied, and the animal treated to three months' rest in a small paddock, the end of a barn, or a roomy loose-box. In persistent cases, firing or setoning usually gives much relief.

SPEAKER, the name given to the presiding officer in either House of Parliament. In the House of Lords, the Lord Chancellor, or Lord Keeper of the Great Seal, is *ex officio* Speaker; and one or more deputy-speakers are appointed by commission to take his place in his absence. Since 1851, it has been the practice to appoint but one deputy-speaker, who is the chairman of the Lords' committee, and should he also be absent, the House can choose a Speaker *pro tempore*. The Speaker of the Lords may speak or vote on any question, and has no more authority than any other member of the House.

In the House of Commons, the Speaker is a member elected to that office at the desire of the crown, and confirmed by the royal approbation given in the House of Lords. A similar office seems to have existed as early as the reign of Henry III., when Peter de Montfort signed and sealed an answer of the parliament to Pope Alexander, *vice totius communitatis*; but the title Speaker was first given to Sir T. Hungerford in the reign of Edward III. The Speaker of the House of Commons presides over the deliberations of the House, and enforces the rules for preserving order: he puts the question, and declares the determination of the House. As the representative of the House, he communicates its resolutions to others, and conveys its thanks or its censures. He is thus the mouthpiece of the House, whence his title seems to be derived. He issues warrants in execution of the orders of the House for the commitment of offenders, for the issue of writs, the attendance of witnesses, the bringing up prisoners in custody, &c. The mace is borne before him by the serjeant-at-arms when he enters or leaves the House; when he is in the chair, it is left on the table, and it accompanies him on all state occasions. He cannot speak or vote on any question, but on an equality of voices he has a casting vote. Both by ancient custom and legislative declaration, he is entitled to take precedence of all commoners.

In the year 1853 the House, with consent of the crown, resolved that in the absence of the Speaker the Chairman of the Committee of Ways and Means should take the chair, and as deputy-speaker he was in 1855 invested, both by resolution of the House and by act of parliament, with the same authority *pro tempore* as the Speaker. In the United States the presiding officer of the House of Representatives of the United States, and presiding officer of each branch of the state legislatures, generally, is called the Speaker

SPEAKING. See READING.

SPEAKING-TRUMPET, an instrument for giving concentration rather than dispersion to the waves of sound originated by the articulation of the human voice, and thereby enabling the sound to be conveyed to a greater distance. It is of the utmost use on shipboard in enabling the officers to convey orders during windy weather from one part of the deck to another, or to the rigging. The invention is ascribed to Sir Samuel Morland, in 1670, though Athanasius Kircher laid claim to it. Morland's trumpet was of the same form as that now in use—viz., a truncated cone, with an outward curve or lip at the opening.

The theory of the action of this instrument has never been thoroughly explained; but it is supposed that the sides of the tube throw the sound back and back in various reflections, until ultimately the waves quit the instrument in parallel lines. It does not seem to depend on vibration of the instrument.

SPEAR, a pointed weapon with a shaft of greater or less length for thrusting, throwing, or receiving an assault. See JAVELIN, LANCE, PIKE.

The *spear foot* of a horse is his far foot behind

SPE'CIES, in Natural History, a term employed to designate groups inferior to genera (see GENUS), but superior to varieties (see VARIETY). In Mineralogy, the term is of very arbitrary application, serving only, like class, order, genus, &c., the purpose of classification, although it thus indicates common characters or points of real agreement among minerals. In organic nature, it has usually been regarded as possessing a higher and more definite signification. No term is more difficult to define.

Naturalists have very generally regarded species as unchanging throughout the longest succession of generations, except within narrow and marked limits, and have substantially adopted the definition of Buffon: 'A *species* is a constant succession of individuals similar to and capable of reproducing each other.' Thus De Candolle, the eminent botanist, says: 'We unite under the designation of a *species* all those individuals that mutually bear to each other so close a resemblance as to allow of our supposing that they may have proceeded originally from a single being or a single pair.' And Cuvier, the great zoologist, describes a species as 'a succession of individuals which reproduces and perpetuates itself.' Here it may be remarked, that even if the permanence of species implied in these definitions were fully ascertained, and their original creation in their present form admitted as unquestionable, it would by no means follow that we must suppose every species to have proceeded from a single individual or a single pair.

But the separate creation and immutability of species are disputed, some naturalists maintaining that species undergo modification, and that existing forms of life have descended by true generation from pre-existing forms. Lamarck was the first to proclaim this doctrine, at least so as to attract much attention, about the beginning of the 19th century. He held that all species, even including man, are descended from species of inferior organisation; whilst to account for the existence of very simple forms at the present day, he had recourse to the supposition of their spontaneous generation. He was followed, with greater caution, by Geoffrey Saint-Hilaire, who regarded what we call species as various degenerations of the same type, but did not believe that the existing species are now undergoing modification. Similar views have since been stated by many authors. But the works which have most strongly directed attention to them, and in which they have been most fully advocated, are the *Vestiges of the Natural History of Creation*, by an anonymous author, published in 1844, and Darwin's work *On the Origin of Species by means of Natural Selection*, published in 1859. This law was independently discovered by Alfred Russell Wallace. Of the other supporters of these views, one of the most eminent is Professor Huxley, who, without fully adopting the views either of the author of the *Vestiges* or of Darwin, advocates 'the hypothesis which supposes the species living at any time to be the result of the gradual modification of pre-existing species,' and maintains that to suppose each species of plant and animal to have been formed and placed on the surface of the globe at long intervals by a distinct act of creative power, is an assumption 'as unsupported by tradition or revelation as it is opposed to the general analogy of nature.'

It is impossible for us to do more than very briefly exhibit the principal arguments which have been urged on this question. Lamarck rested much on the well-known effect of use or exercise in strengthening and enlarging an organ, and of disuse in atrophying it. 'He conceived that, an animal being brought into new circumstances, and called upon to accommodate itself to these, the exertions which it consequently made to that effect caused the rise of new parts; on the contrary, when new circumstances left certain existing parts unused, these parts gradually ceased to exist. Something analogous was, he thought, produced in vegetables, by changes in their nutrition, in their absorption and transpiration, and in the quantity of caloric, light, air, and moisture which they received. This principle, with time, he deemed sufficient for the advance from the monad to the mammal.' The author of the *Vestiges*, from whom this account of Lamarck's views is taken, regards him as in error 'in giving this adaptive principle too much to do;' and says: 'In the present day, we have superior light from geology and physiology, and hence comes the suggestion of a process analogous to ordinary gestation for advancing organic life through its grades, in the course of a long but definite space of time, with only a recourse to external conditions as a means of producing the exterior characters.'

Darwin's views are distinguished by the introduction of what he designates the principle of *Natural Selection*. He maintains the variability of species, and adduces much evidence to shew that variation is continually taking place, in consequence of the external conditions to which plants and animals are subjected. He rests much on the difficulty of distinguishing between varieties and species, and on the changes which are known to result from cultivation and domestication. He dwells on the *selection* which man makes, in order to produce new breeds or varieties, and supposes a similar 'selection' to take place in nature, in the *struggle for life*, which all plants and animals must undergo. This *struggle for life* is, in fact, the foundation of his theory. He shews that every kind of plant or animal must maintain it, and in order to give to it continued existence, must be successful in maintaining it, not only against those other creatures which seek to make it their food, but still more in a competition with those which seek the same nutriment with itself. In this struggle, the stronger, or those which possess anything peculiarly favourable in their organisation, must overcome the weaker, and these must therefore cease to exist. Thus a slight variation, such as often takes place, may be perpetuated; and the possessors of any advantage in the means of procuring food, or in the powers of offence or defence, may entirely displace their less favoured congeners. The modifications thus taking place, Darwin regards as accounting for the changes in organised beings from one geologic period to another, and for the great differences in the plants and animals of different parts of the world. In support of his views, he argues from the tendency to variation seen in cultivated plants and domestic animals, and the perpetuation of the forms so produced in breeds and races; and from the fact, that the variations in cultivated and domestic species are in some cases greater than those which are regarded as affording grounds of specific, and sometimes even of generic or greater distinctions in a state of nature.

Mr Darwin supposes new variations to be continually taking place, but the greater number of these speedily to become extinct; whilst others, becoming perpetuated, and perhaps causing the extinction of the original forms, again give rise to other forms, until some of them have so widely diverged, that all traces of their common origin are lost. He does not, however, commit himself to the opinion that all forms of organic life, or even all plants, or all animals, have a common origin. He completely rejects Lamarck's notion that new and simple forms are continually being produced by spontaneous generation. 'I need hardly say,' he remarks, 'that science in her present state does not countenance the belief that living creatures are now ever produced from inorganic matter,' and he accounts for the existence of low forms of life by saying that 'natural selection includes no necessary and universal law of advancement or development; it only takes advantage of such variations as arise and are beneficial to each

creature under its complex relations of life.' So that even the lowest forms might 'be left by natural selection unimproved, or but little improved,' as geology tells us of infusoria and rhizopods, which have remained for an enormous period in nearly their present state.

That species differ not only in single characters, but in many, Mr Darwin accounts for by reference to unknown laws of the correlation of organs—laws, however, which, although unknown, we know to exist, so that a modification of one organ is attended with modification of other organs, as is exemplified in our domestic breeds.

In further support of the theory of natural selection, the fact is insisted upon, 'that it is the common, the widely-diffused, and widely-ranging species, belonging to the larger genera within each class, which vary most.' He points also to the analogous manner in which species of the same genus vary, as corroborative of his views. He accounts for the absence or rarity of transitional varieties by supposing the predominant forms to have taken possession of their districts, whilst these were in process of being stocked; and that, these districts differing much in their natural characters, the forms originating in the comparatively unextensive intermediate tracts have not been able to contend against them, and have become extinct. He points out the possibility that areas now continuous may not have been so during a long period, and that species may have been formed whilst they were broken up into islands. But this remains a chief difficulty of his theory.

He ascribes to natural selection the results which Lamarck ascribed to use and disuse in the development and atrophy of organs; and thinks it not impossible that the flying squirrels may thus have had a common origin with the true squirrels, and the *Galeopithecus* with the lemurs, although he admits that we have no graduated links of structure connecting them together. 'Nor can I see any insuperable difficulty,' he says, 'in further believing that the membrane-connected fingers and forearm of the *Galeopithecus* might be greatly lengthened by natural selection; and this, as far as the organs of flight are concerned, would convert it into a bat.' Like Lamarck and the author of the *Vestiges*, Mr Darwin rests not a little on the unity of type throughout whole classes of creatures, and the homologies of parts very different from each other, as in the four-limbed structure of the vertebrata generally, and even the articulations of the limbs. He endeavours to trace the eye from its simplest to its most perfect form, and shews how gradual are the transitions found on comparison of existing creatures, from the one to the other. He goes even further, and says: 'Several facts make me suspect that nerves sensitive to touch may be rendered sensitive to light, and likewise to those coarser vibrations of the air which produce sound.'

He dwells at great length on the subject of hybridism and the general sterility of hybrids, endeavouring to shew that it presents no insuperable objection to the theory of a gradual modification of species, their sterility being incidental on other differences, and sterility occurring, as he labours to prove, when varieties are crossed as well as in the hybrids of distinct species. The difficulties presented by geology he obviates very much by insisting on the imperfection of the geological record. He does not adopt the view of the author of the *Vestiges*, that the geological record exhibits to us a succession of animals, corresponding in their progressive development with the fœtal development of the mammalian embryo But he founds an argument on the many connecting links in the general system of nature which fossils supply when compared with existing species. And he endeavours to shew that his theory is perfectly consistent with the known facts of the geographical distribution of species, and in particular with the remarkable facts of the peculiarity of the fauna and flora of some of the lonely oceanic islands, and of the frequent occurrence of the same species both in cold regions comparatively near the pole, and on mountains far remote from each other in lower latitudes; referring the latter class of facts to former geologic periods, when the continental areas were not the same as now, or when the prevailing climatic conditions were very different. And he finds support for his views in the correspondence, without identity, of the floras and faunas of the northern parts of America and of the Old World.

Whatever may be thought of the truth of this theory, it must be admitted to be admirably framed and guarded, and to be maintained not only with great ingenuity of argument, but by the aid of a vast store of scientific information, most skilfully used. Its opponents condemn it as resting on unwarrantable assumptions, and demand some proof, for example, of the transition of organs from a simple or rudimentary to a complex and more perfect state. They also refuse to acknowledge such imperfection of the geological record as Darwin's argument demands, and they insist much on the completeness of the changes which that record discloses, and the absence of transitional forms both among fossils and existing species. Much of what Darwin and other advocates of the same general views contend for, they admit; a certain power of development in organic nature, a 'struggle for life,' and 'natural selection;' but they regard the limits of development and variation as comparatively narrow. Nor would the state of the question, as they believe, be materially affected, if many of what have hitherto generally been regarded as species should be proved to be mere varieties. Any number of such errors of naturalists might be exposed and corrected, without modification of our views of the laws of nature.

The last of these hypotheses, and the most promising of them all, says Principal Dawson, is that which has recently been ably advocated by Prof. Edward D. Cope in memoirs on the 'Origin of Genera,' and the 'Method of Creation,' and which is based on the well-known analogy between embryonic changes, rank in zoological scale, and geological succession.

Its author considers it under four distinct heads, or theories, viz., (1) the theory of Acceleration and Retardation; (2) the theory of Repetitive Addition; (3) of Use and Effort; and (4) of the Conversion of Grade Force.

The *first* is explained as follows, and includes a demonstration of the existence of evolution.

It is well known that in both kingdoms, in a general way, the young stages of the more perfect types are represented or imitated with more or less exactitude by the adults of inferior ones. But a true identity of these adults with the various stages of the higher has, comparatively, rarely been observed. Let such a case be supposed:

In *A* we have four species whose growth attains a given point, a certain number of stages having been passed prior to its termination or maturity. In *B* we have another series of four (the numbering a matter of no importance), which, during the period of growth, cannot be distinguished by any common, *i. e.*, generic, character, from the individuals of group *A*, but whose growth has only attained to a point short of that reached by those of group *A* at maturity. Here we have a parallelism, but no true evidence of descent. But if we now find a set of individuals belonging to one species, and therefore held to have had a common origin or parentage (or still better the individuals of a single brood), which present differences among themselves of the character in question, we have gained a

point. We know in this case that the individuals, *a*, have attained to the completeness of character presented by group *A*, while others, *b*, of the same parentage have only attained to the structure of those of group *B*. It is perfectly obvious that the individuals of the first part of the family have grown further, and, therefore, in one sense, faster, than those of group *B*. If the parents were like the individuals of the more completely grown, then the offspring which did not attain that completeness may be said to have been *retarded* in their development. If, on the other hand, the parents were like those less fully grown, then the offspring which have added something have been *accelerated* in their development.

It is claimed that a consideration of the uniformity of nature's processes, or inductive reasoning, requires us to believe that the groups of species whose individuals have never been found to vary, but which differ in the same point as those in which the above variations have been observed, are also derived from common parents, and the more advanced have been *accelerated* or the less advanced *retarded*, as the case may have been with regard to the parents.

This is not an imaginary case, but a true representation of many which have come under observation. The developmental resemblances mentioned are universal in the animal and probably in the vegetable kingdom, approaching the exactitude above depicted in proportion to the near structural similarity of the species considered.

Example.—It is well known that the *Cervidæ* of the Old World develop a basal snag of the antler (see Cuvier, *Ossemens Fossiles*, and Gray, *Cat. British Museum*) at the third year; a majority of those of the New World (genera Subulo, Cariacus) never develop it except in abnormal cases in the most vigorous maturity of the most northern Cariacus (*C. Virginianus*), while the South American Subulo retains to adult age the simple horn or spike of the second year of all *Cervidæ*. Among the higher *Cervidæ*, Rusa and Axis never assume characters beyond an equivalent of the fourth year of Cervus. Now an abundant race of the American deer, *Cariacus Virginianus*, exists in the Adirondack region of New York, in which the development of the antlers never progresses beyond the spike stage of the second year. Therefore, some of this species belong to Cariacus and some to Subulo.

Another remarkable case illustrating this view is seen in the *Siredon* type of aquatic Batrachia which inhabits the waters of Mexico. They are permanent larvæ of salamanders, of the genus *Amblystoma*, which inhabit North America; that is, they are at maturity identical with the young of the latter genus. But it has been observed that the larva of *Amblystoma* will, in suitable situations, comport itself like an adult animal, and reproduce young, which may remain like the parent *Siredons*, or permanently larval, or may grow further, and become true *Amblystoma*. Other larva-like genera of Batrachia, as *Necturus*, are similar, but not so exactly related, to genera which undergo metamorphosis.

The remarkable and somewhat startling fact that animals change from one genus or family to another without losing their individuality or specific characters is here presented. We here have actual facts on which to base a theory of development; and similar phenomena have been observed among molluscs, insects, &c.

These facts point to the operation of two causes—first, the possible *Retardation* or *Acceleration* of growth, and secondly, the influence of outward circumstances on the organism capable of retardation or acceleration. The most important result is, that having ascertained the series of embryonic changes of any animal, we have thereby ascertained its possibilities in regard to accelerated development. Its possibilities in regard to retarded development may be inferred by similar studies of animals higher in the scale.

The theory of *Repetitive Addition* is based on that of homology of the parts of animals. It states that the construction of the animal types is restricted to two kinds of increase—the addition of identical segments and the addition of identical cells. The first is probably to be referred to the last, but the laws which give rise to it cannot be here explained. Certain it is that segmentation is not only produced by addition of identical parts, but also by subdivision of a homogeneous part. In reducing the vertebrate or most complex animal to its simplest expression, we find that all its specialized parts are but modifications of the segment, either simply or as sub-segments of compound but identical segments. Other animals which present cavities or parts of a solid support are still more easily reduced to a simple basis of segments, arranged either longitudinally (worm) or centrifugally (star-fish, &c.).

Each segment is constructed, as is well known, by cell division. In the growing fœtus the first cell divides its nucleus and then its whole outline, and this process repeated millions of times produces, according to the cell theory, all the tissues of the animal organism or their bases from first to last. That the ultimate or histological elements of all organs are produced originally by repetitive growth of simple nucleated cells, with various modifications of exactitude of repetition in the more complex, is taught by the cell theory. The animal organism transfers the chemism of the food (protoplasm) to correlated amounts of heat, motion, electricity, light (phosphorescence), and nerve force. But cell division is an affection of protoplasm distinct from any of these. Addition to homogeneous lumps or parts of protoplasm (as in that lowest animal, *Protamœba* of Haeckel) may be an exhibition of mere molecular force, or addition, as is seen in the crystal, but cell division is certainly something distinct. It is called *Growth force*, and has been shown by Henry and Carpenter to be correlated to chemism, heat, &c. The whole question, then, of the creation of animal and vegetable types is reduced to one of the amount and location of growth force.

The theory of *Use and Effort* states that the influences locating growth force are: first, physical and chemical causes; second, use; third, effort. The first is not especially prominent in the economy of type growth among animals, and is less important than the two following. The effects of use are well known. We cannot use a muscle without increasing its bulk; we cannot use the teeth in mastication without inducing a renewed deposit of dentine within the pulp-cavity to meet the encroachments of attrition. The hands of the labourer are always larger than those of men of other pursuits. Pathology furnishes us with a host of hypertrophies, exostoses, &c. produced by excessive use, or necessity for increased means of performing excessive work. The tendency, then, induced by use in the parent is to add segments or cells to the organ used. Use thus determines the locality of new repetitions of parts already existing, and determines an increase of growth force at the same time by the increase of food always accompanying increase of work done, in every animal.

But supposing there be no part or organ to use. Such must have been the condition of every animal prior to the appearance of an additional digit or limb or other useful element. It appears that the cause of the determination of growth force is not merely the irritation of the part or organ used by contact with the objects of its use.

In many instances which might be cited, it cannot be asserted that the nutrition of use is not under the direct control of the will through the mediation of nerve force. Therefore growth force may be, by the

volition of the animal, as readily determined to a locality where an executive organ does not exist, as to the first segment or cell of such an organ already commenced, and therefore effort is, in the order of time, the first factor in acceleration.

Effort and use have, however, very various stimuli to their exertion.

Use of a part by an animal is either compulsory or optional. In either case the use may be followed by an increase of nutrition under the influence of reflex action or of direct volition.

A compulsory use would naturally occur in new situations which take place apart from the control of the animal, where no alternatives are presented. Such a case would arise in a submergence of land, where land animals might be imprisoned on an island or in swamps surrounded by water, and compelled to assume a more or less aquatic life.

Preservation with modifications would only ensue where the changes should be introduced very gradually. This mode is always a consequence of the optional use. The cases here included are those where choice selects from several alternatives, thus exercising its influence on structure. Choice will be influenced by the emotions, by the imagination, and by intelligence.

The selection of food offers an opportunity for the exercise of intelligence, and the adoption of means for obtaining it still greater ones. It is here that intelligent selection proves its supremacy as a guide of use, and consequently of structure, to all other agencies proposed. The choice of food under ground, on the ground, or in the trees would necessarily direct the uses of organs in those directions respectively.

Intelligence is a conservative principle, and always will direct effort and use into lines which will be beneficial to its possessor. Thus we have the source of the fittest—*i.e.*, addition of parts by increase and location of growth force directed by the will—the will being under the influence of various kinds of compulsion in the lower and intelligent option among higher animals. Thus *intelligent choice* may be regarded as the ultimate originator of the fittest, while *natural selection* is the tribunal to which all the results of accelerated growth are submitted. This preserves or destroys them, and determines the new points of departure on which accelerated growth shall build.

Acceleration under the influence of effort accounts for the existence of rudimental characters. Many other characters will follow at a distance, the modifications proceeding in accordance with the laws here proposed, and retardation is accounted for by complementary or absolute loss of growth force.

The fourth theory, that of the Conversion of Grade Force, is the most obscure. The proposition is thus stated:

Acceleration is only possible during the period of growth in animals, and during that time most of them are removed from the influence of physical or biological causes, either through their hidden lives or incapacity for the energetic performance of life functions. These influences must, then, have operated on the parents, been rendered potential in their reproductive cells, and become energetic in the growing fœtus of the next generation. However little we may understand this mysterious process, it is nevertheless a fact. Says Murphy, 'There is no act which may not become habitual, and there is no habit that may not be inherited.' Materialized, this may be rendered —there is no act which does not direct growth force, and therefore there is no determination of growth force which may not become habitual; there is, then, no habitual determination of growth force which may not be inherited, and of course in a growing fœtus becomes at once energetic in the production of new structure in the direction inherited, which is acceleration. The explanation of this phenomenon has not yet been attained. That which is communicated through the reproductive elements is a special or specific kind of capacity for the conversion of heat to growth force, and it is assumed that in acceleration more of this is communicated, in retardation *less* of it, than in previous generations.

SPECI'FIC GRAVITY of any body is the proportion which the weight of a certain bulk of that body bears to the same bulk of another body, which is taken as a standard. The standard for substances solid and liquid is distilled water at the temperature of 62° Fah., barometer 30 inches; and the weight of a cubic inch of this standard is given in the Parliamentary Reports for 1825 as 252·456 troy grains, hence a cubic foot of it weighs 997·129 avoirdupois ounces, or 62·32 avoirdupois pounds. It is convenient to remember that a cubic foot of water weighs about 1000 ounces avoirdupois, as the error resulting from employing this estimate does not amount to much more than $\frac{1}{350}$th of the whole. For aëriform bodies, the standard is atmospheric air, a cubic inch of which, at a temperature of 32° Fah., weighs ·32698, and at 60° Fah., ·30935 grains troy. The specific gravity of solid bodies is best measured by the hydrostatic balance—a figure of which is given under ARCHIMEDES, PRINCIPLE OF (q. v.)—which gives the weight of a volume of water equal in bulk to the solid, by which it is only necessary to divide the weight of the solid in air to obtain the specific gravity; that of liquids may be obtained by the Areometer (q. v.), or by comparing the weight lost by a solid body in the liquid and in water, and dividing the former by the latter—or by means of the *specific-gravity bottle*, which holds exactly 1000 grains of distilled water in its standard condition. The bottle is emptied of water, filled with the liquid, and then weighed; the result gives the weight of a volume of the fluid equal in bulk to 1000 grains of the standard, and hence this weight divided by 1000 gives the specific gravity. The specific gravity of an aëriform fluid is determined by weighing a glass globe filled first with the fluid, and then with atmospheric air. Annexed is a table of the specific gravity of a few of the more common substances.

SPE'CTACLES, for the purpose of aiding the sight when impaired by age or otherwise (see SIGHT, DEFECTS OF), were invented during the 13th century. The merit is attributed by some to Alexander di Spina, a Florentine monk, and by others to Roger Bacon. At first, they were exceedingly clumsy, both in the lenses themselves and also in their frames; and but little improvement took place in them until the beginning of this century, when light metal frames were introduced, instead of the cumbrous horn or tortoise-shell mountings, which are still occasionally seen, and have obtained the name of goggles. So skilful are the workmen of Wolverhampton, where they are chiefly made, in the manufacture of steel frames, that some of exquisite workmanship are now turned out, which, with their lenses complete, are under a quarter of an ounce in weight. They have consequently displaced gold, silver, and all other materials, when comfort and effectiveness are preferred to useless show combined with inconvenience. The lenses themselves are nearly always made of the best optical glass, and by the best makers are ground with extreme care. Many profess to be made of 'pebbles,' or rock-crystal; but lenses really made of that material are exceedingly rare, and have no real advantage over good glass.

SPECTRE BAT (*Phyllostoma*), a genus of bats having two membranous crests on the nose, the one leaf-like, the other in the form of a horseshoe. This gives to their face that peculiar appearance from which they derive their popular as well as their scientific name. The molar teeth in all the spectre bats have sharp points and edges, shewing that they are very carnivorous. The tongue is extensile and rough, so that it is supposed capable of being used as an instrument both of abrasion and of suction. Their blood-sucking powers have been doubted by some naturalists, among whom is Cuvier, but are now fully established. See VAMPYRE. The species are numerous, and all natives of the West Indies and South America. Some of them are among the largest tropical bats.

SPE'CTRUM (Gr.) is a term applied in Optics to the coloured image of the sun or other luminous body, produced by Refraction through a Prism (q. v.), by Diffraction (q. v.) through a fine grating, &c. In what follows we shall confine ourselves to the spectrum produced by a prism, as that which is commonly used. Besides, so far as we have at present occasion to examine it, it presents very nearly the same appearances as spectra produced by other processes.

The solar spectrum was first carefully examined by Newton, who deduced from his observations the composite nature of white light, and the different refrangibilities of its various coloured constituents. A ray of sunlight enters a darkened room through a small hole, S, in a shutter. It proceeds in a straight line to the opposite wall, and forms at S′, as a circular white spot, an image of the sun. If the edge of a glass prism, P, be interposed in the path of this

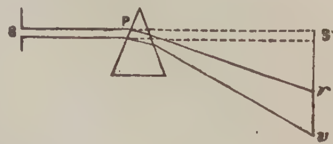

Fig. 1.

ray, the white spot at S′ disappears, and the spectrum, *r*, *v*, is produced. In this form of experiment, its shape is that of a rectangle with semicircular ends, as figured below.

Fig. 2.

The breadth of the spectrum is equal to the diameter of the spot S′; and it is brilliantly coloured, the end *r*, nearest to S′, being red, and the other end, *v*, violet. Between these we have gradations of colour, and the whole appeared to Newton to be divisible into seven differently coloured spaces, which he called red, orange, yellow, green, blue, indigo, violet. This was in accordance with the speculations of old days, when analogies were constantly looked for, and seems to have been suggested to Newton by the common musical scale. It is impossible, however, to settle precisely the exact boundary between any two of these fancied species of colour; and, besides, such a description of the spectrum (though complete enough for mere popular language) is totally inadequate to express our present knowledge of the subject. In order to study the spectrum a little more closely, suppose we have pieces of coloured glass which allow only one definite colour to pass. With a red glass placed at the hole in the shutter, the prism being removed, the effect would be to render the spot S′ red, without changing its position. Introduce the prism, and the effect is to change the position of the spot to *r*, without altering its size or colour.

Fig. 3.

Similarly, with a violet glass we have a violet spot at *v*, and so on; the change of position, due to refraction, being least for red and greatest for violet. It thus appears that the spectrum formed in this way, is made up of a series of circular spots, of the various colours of which white light consists, all of the same size, and having their centres ranged along a line, so that each overlaps those next it. The only parts of the spectrum which are *pure*, i. e., where no two or more colours are mixed, are the ends; so that, by this process, it is impossible to separate definitely the rays of different refrangibility, so as to see, for instance, *whether any are wanting.* How, then, are we to ascertain whether sunlight contains rays of every refrangibility from red to violet? The obvious method is to make the

spot S′ not circular, but long and very narrow, a process mentioned by Newton himself. In such a case our figure would become

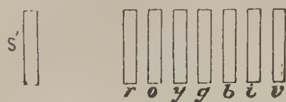

Fig. 4.

and, by making S′ narrow enough, we shall evidently be able to avoid overlapping of the various coloured images, *unless there be present, in white light, rays of every refrangibility from red to violet.* To make this spot S′ thus narrow, a method commonly employed, is to set the prism about half-way between the shutter and the screen, and to place before it a lens, such that, if the prism were removed, S′ would be an image of the hole in the shutter nearly equal to it in size. The hole must, therefore, be a narrow slit, parallel to the edge of the prism. When this arrangement is adjusted we have a pure spectrum, and we find it to be (at first sight) *continuous.* Thus, it appears that sunlight contains rays of every refrangibility, from the highest to the lowest; and that Newton's sevenfold division of it, though sometimes convenient for popular reference, has no scientific basis. Besides, what we can see is not the whole spectrum but a mere fraction of it; for beyond the red end, there are invisible rays recognised at once by their heating powers; and beyond the violet, there are invisible rays more powerful than the visible in producing chemical changes, as on a photographic plate, and which can be changed into visible rays by fluorescent substances. See PHOSPHORESCENCE. The breadth of the visible spectrum evidently depends on the *length* of the slit, its length on the difference of refrangibility of red and violet.

If we cut a narrow slit in the screen on which the spectrum falls, in a direction perpendicular to its length, the light which passes through has a definite refrangibility, and can no longer be drawn out by a prism into a spectrum. This experiment also is due to Newton.

If the slit in the shutter be very narrow, and the prism be adjusted to the most favourable position (so that the incident and refracted rays make equal angles with the surfaces on which they impinge, and from which they escape, respectively), we see that, after all, the solar spectrum is *not* continuous. It is found to be crossed at intervals by dark bands (a few of which are sketched below, fig. 5), shewing the absence of rays of certain definite refrangibilities. The phenomenon is found to be the same whatever be the substance of the prism; so that these rays are really wanting in sunlight.

This important discovery was made by Wollaston, but the bands were first carefully observed and measured by Fraunhofer, from whom they are commonly called *Fraunhofer's Lines.* We owe to Fraunhofer the invaluable suggestion of employing a telescope to examine the spectrum. The refracted rays are received directly on the object-glass of the telescope, which forms an image of the spectrum to be examined with the aid of the eye-piece, the screen being dispensed with. Wollaston had seen only five lines; Fraunhofer at once discovered four hundred; Brewster, with more perfect apparatus, counted two thousand; and now, with a train of prisms, and powerful telescopes, their number seems beyond computation. They shew every variety of breadth and distinctness, and are grouped in the most irregular manner. For reference, Fraunhofer selected some of the more prominent, to which he attached the earlier letters of the alphabet. By their help he was enabled to measure refractive indices (see REFRACTION) with a precision completely unlooked for. If the light of a candle, a bright gas-flame, a white-hot wire, or a lime-ball in the oxyhydrogen flame, be examined in the same way, *no such lines are seen.* But some of them, and others not apparently belonging to sunlight, were found by Fraunhofer in the spectra of various fixed stars—while the light of the moon and planets seemed to give spectra similar to that of sunlight.

The first to throw any light on this subject was Brewster. He shewed that when light passed through nitrous acid gas its spectrum was interrupted by countless lines; and that they increased in number and breadth by the application of heat to the gas, so that at a high temperature a thin layer of this gas is *opaque to direct sunlight.* Hence it was natural to conclude that the dark bands in the solar spectrum are caused by absorption in some medium lying between us and the sun. It is to be observed, however, that this is on the supposition that light as it comes immediately from the sun would give, like that of the lime-ball, a continuous spectrum. But Brewster went farther. He shewed that *some* of Fraunhofer's lines depend on the altitude of the sun, that is on the greater or less space of air, fog, and vapour through which his rays must pass before reaching the earth. *Some of them,* then, *are caused by absorption in the earth's atmosphere.*

But we must now look to another class of phenomena. A spirit-lamp flame gives a very feeble spectrum; and, if a little common salt be put on the wick, although the flame becomes instantly very much brighter, no alteration is produced on the spectrum save the appearance of a *bright* yellow line crossing it at the place where the dark line, called by Fraunhofer, D, appears in sunlight. On examining this line carefully, Fraunhofer found that it, like D, is double—and he verified that these two rays were exactly (so far as refractive index goes) two of those wanting in sunlight, and in the light of some of the stars.

About the same time Talbot and Herschel (q. v.) shewed that the colours given by Lithia, Strontia, &c., in a spirit-flame were, like that produced by common salt, due to the production of light of several perfectly definite refrangibilities: so that the spectrum of the lamp-flame was crossed in each case by a series of bright lines, always the same when the same body was placed in the flame; and they suggested (in 1825) the application of this method to the qualitative analysis of minerals, &c., when the presence of extremely minute quantities of different bodies has to be ascertained. This was, in reality, the foundation of SPECTRUM-ANALYSIS; and the method was, we may say, almost complete so far as practice is concerned. The theory, however, was left incomplete so far as regards the cause of dark lines in the solar spectrum. Foucault (in 1849) seems to have been the first to approach the true explanation. An experiment of his, from which, however, he drew no inferences, contains the complete theory. When salt is placed in the voltaic arc (ELECTRIC LIGHT, q. v.) the spectrum gives the double bright line (coinciding with the double dark line D) already referred to. When sunlight passes through this arc its dark line D is *strengthened,* instead of being filled up, by the yellow light from the arc as we might have expected; and when one of the white-hot carbon-points (which gives a continuous spectrum) is looked at through the yellow arc, the double dark line D appears in its spectrum.

Stokes learning, in 1850, that experiments had been made by Professor Miller of Cambridge, to

test with great accuracy Fraunhofer's assertion as to the exact coincidence of the double bright line of a salted flame with the double dark line of the solar spectrum, gave for the first time the physical explanation of the phenomenon. He compared the salt-flame to a space full of tuning-forks or pianoforte wires all tuned to the same note. When they are in vibration they, of course, give out this note —similarly the salt-flame the *bright* lines. When, however, sounds are produced in their neighbourhood, as they naturally vibrate to one definite note, they will be set in vibration by it (i. e., will absorb it) if it be part of the sound.—Thus sound which has passed through such a space has had this note eliminated from it—similarly the salt-flame seizes these yellow rays from white light passing through it. This ingenious and satisfactory explanation shews at once that the line D proves the existence of salt (or sodium) in the atmosphere of the sun. Stokes's theory was not published, except in so far as it was annually given by W. Thomson (q. v.) in his lectures in Glasgow—so that it was independently discovered, or all but discovered, by various other philosophers some 8 or 10 years later. The earliest of these was Balfour Stewart of the Kew Observatory, who proved by reasoning and experiment that a body's absorbing power for any ray of light or heat is equal to its radiating power for the same. Augström all but made the rediscovery. Finally, Kirchhoff, by reasoning similar to that of Stewart, and by actually reversing the spectra of certain substances, arrived at the same results; and, in conjunction with Bunsen, applied them to chemical analysis, with the immediate result of discovering two new metals.

One of the most valuable parts of Kirchhoff's investigation, is his map of the solar spectrum with its dark lines; side by side with which is a spectrum containing the bright lines given by various metals volatilised in an electric spark. The sunlight is admitted through the upper half of the slit, the light from the burning metal through the lower—and thus the two are subject to precisely the same deflections by the train of prisms. The following figure shews a very small portion of Kirchhoff's drawing, and exhibits the exact coincidence of the bright lines produced by highly heated vapours of iron, manganese, nitrogen, and calcium, with corresponding dark lines in the solar spectrum. The particular portion exhibited (in the middle of the green), is chosen because it contains few lines whose origin has not been ascertained. But *every* bright line in the iron spectrum has a corresponding dark line in the solar spectrum. Kirchhoff has calculated

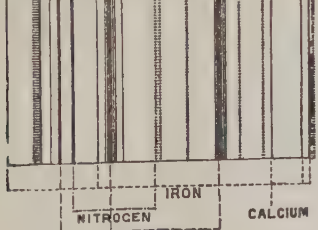

Fig. 5.

from his data the probability that the sun's atmosphere contains iron; and finds it to differ from certainty by a quantity almost inconceivably small.

The applications of the spectrum-analysis are becoming more numerous every day. We have space only for two of the most beautiful and important. Huggins has lately shewn that the spectra of planetary nebulæ, and of the tails of comets, consist of a few *bright* lines only—indicating that these bodies—or, at all events, those portions of them from which their light proceeds—are masses of incandescent vapours or gases.

Again, Stokes has traced, by the alteration of the absorption bands produced by the colouring matter of blood, the oxidation and reduction which constantly take place in this substance, and its connection with the distinction between venous and arterial blood.

SPE'CULUM METAL, an alloy of copper and tin, used for making the reflecting surfaces of reflecting telescopes. The best consists of 126·4 parts copper to 58·9 tin. To obtain a perfect alloy, and to cast it successfully, is a matter of great difficulty, requiring much skill and experience. See TELESCOPE.

SPEE'DWELL (*Veronica*), a genus of plants of the natural order *Scrophulariaceæ*, distinguished by

Germander Speedwell (*V. Chamædrys*).

a 4-cleft wheel-shaped corolla, with the lower segment narrower, two stamens, and a two-celled capsule. The species are very numerous, annual and perennial herbaceous plants and small shrubs, natives of temperate and cold climates in all parts of the globe. Some of them grow in wet ditches and in marshes, some only on the driest soils. They have generally very beautiful blue, white, or pink flowers. The number of British species is considerable, and few wild-flowers are more beautiful than the Germander S. (*V. Chamædrys*), or the alpine species, *V. alpina* and *V. saxatilis*. A number of species are very generally cultivated in flower-gardens.—The bitter and astringent leaves of the COMMON S. (*V. officinalis*), one of the most abundant British species, found also in almost all the northern parts of the world, are in some countries used as a tonic, sudorific, diuretic, and expectorant medicine. They are also employed, particularly in Sweden, as a substitute for tea; as are those of the Germander S., which are said to afford a really pleasant beverage.—*V. Virginica* is called *Calver's Physic*; it is said to be actively diuretic, and a decoction of the fresh root is violently cathartic and emetic.—Brooklime (q. v.) belongs to this genus.

SPEKE, JOHN H. See SUPPLEMENT in Vol. X.

SPELE'RPES, *Raf.* A genus of tailed Batrachia peculiar to North America and Mexico, having biconcave vertebræ, cartilaginous carpus and tarsus, patches of pterygoid teeth, and a mushroom-shaped tongue.

SPELT. See WHEAT.

SPELTER. See ZINC.

SPENCER, JOHN CHARLES, EARL, English minister and statesman, son of the second earl, was born in 1782.—The third earl, the subject of this notice—better known under the courtesy title of Lord Althorp—was educated at Harrow School, and afterwards at Trinity College, Cambridge. He entered parliament in 1804 as member for Oakhampton. In 1806, his father took office as Secretary of State for the Home Department in the Grenville-Fox ministry, and S. became a junior Lord of the Treasury. He was returned for Northamptonshire, which he represented from 1806 until the period of the Reform Bill. In the Reformed parliament he sat for the southern division of the county. He went out with the Whigs in 1807, and during the long interval of their exclusion from office, steadily opposed the measures of the Tory government. On the dissolution of the Wellington cabinet in November 1830, he was appointed Chancellor of the Exchequer and leader of the House of Commons in the celebrated Reform ministry of Earl Grey. The Reform Bill was introduced by Lord J. Russell (q. v.), but the task of carrying the bill mainly devolved upon Spencer. In 1833, he brought in and carried the ministerial Bill for reforming the Irish Church. In this memorable working session, the curious statistician discovered that S., who had, from his post of ministerial leader, naturally been the most frequent speaker, had addressed the House 1026 times, his speeches occupying 387 columns in the then *Mirror of Parliament*. In 1834, he introduced and obtained the assent of the legislature to the Poor-law Amendment Act. When the Irish Coercion Bill was under consideration in the cabinet, S. had opposed the clauses prohibiting public meetings, yet had given way rather than break up the ministry; but when the truth was elicited in debate by Mr O'Connell, S. resigned. He was considered and described by Earl Grey as his 'right-hand man,' and without his assistance the earl felt himself unable to carry on the government. The administration of Viscount Melbourne succeeded (July 1834), in which S. consented to resume his office. In November he was called by the death of his father to the House of Peers, which had the effect of bringing the Melbourne (q. v.) administration to an end. When the attempt of Sir R. Peel to carry on the government failed, S. declined to take office again. He devoted his time to agricultural pursuits, became President of the Smithfield Cattle Club, and suggested the formation of the Royal Agricultural Society, of which he was elected President in 1838. He died at his seat, Wiseton Hall, Notts, October 1, 1845, without issue, and was succeeded by his brother. During his political career, his simplicity of character and integrity of purpose obtained for him the appellation of 'honest Lord Althorp.' He was very little of an orator, but he had a clear and practical intellect, and his influence over the Reformed House of Commons was supreme. Lord Brougham dedicated to him his work on *Natural Theology;* and his *Dialogues on Instinct* are also supposed to be carried on with S., to whose cultivation of philosophy in the midst of his other pursuits, the author bears testimony.

SPENCER, HERBERT. See SUPP. in Vol. X.

SPENCER GULF, a very large and important inlet on the coast of South Australia (q. v.), between Eyria Peninsula on the west, and Yorke Peninsula on the east. It is about 200 miles in length, and is 100 miles in greatest breadth.

SPENER, PHIL. JAK., an illustrious German reformer, and the founder of the sect known as *Pietists*, was born at Rappoltsweiler (Fr. Ribeauville) in Upper Alsace, January 25, 1635. His father was legal adviser to the Count von Rappoltsweiler. At an early age, S. shewed deep religious susceptibilities. After studying the classics at Colmar, he betook himself in 1651 to Strasburg, where the professors Dannhauer and Seb. Schmidt inspired him with a profound love of the Scriptures, not as a heap of dry theological bones, but as a fountain of life and spiritual thought. From 1659 to 1662, he attended the universities of Basel, Tübingen, Freiburg, Geneva, and Lyon. In the following year, he became a preacher at Strasburg, where the unction of his sermons exercised a powerful influence on his hearers. At the age of 31, he was transferred to Frankfürt as first pastor; and here, as elsewhere, the profound spiritualism of the man, springing out of a free simple *un*theological faith in the Bible, made itself apparent in his preaching and life. Yet S. was the very opposite of what is commonly called a *mystic*. The devotion which he sought to excite were not to shew themselves in transcendental ecstasies, amid which common sense is apt to swoon away, but in acts of piety, humility, and charity. The 'Sermon on the Mount' was the medium through which he gazed upon the 'truth as it is in Jesus.' He had a strong aversion to what goes by the name of theology, which he considered a hateful caricature of the free word of life; and he commenced in the year 1670, at his house, meetings for the cultivation of evangelical morality. These were the famous *collegia pietatis*, whose influence for good on the German character, in those days of stony and barren orthodoxy, cannot easily be overvalued. At the same time he took pains to reorganise the method of catechising, and to improve the religious instruction given to children. His conduct in all this was marked by such prudence and discernment, that he long escaped the animadversions of the 'high and dry' Lutherans; but in 1679, a preface which he wrote for a new edition of the *Postille* of Arndt, in which he censured the morals of the upper classes, made him the target for their envenomed shafts; and after some years, he was fain to accept the invitation to become court-preacher at Dresden, and member of the Upper Consistory. In this capacity, he effected important ameliorations in the theological teaching of the university of Leipsic, and in the system of religious catechising practised throughout Saxony; but in 1689 he fell into disgrace for having addressed a temperate but energetic remonstrance to the Elector Johann Georg III., on the subject of his personal vices, was attacked by Carpzow, who coveted his place at court, and by other orthodox theologians, and in 1691 went to Berlin as Provost of the Church of St Nicholas, and consistorial inspector, offices which he retained to the end of his life. The Elector of Brandenburg encouraged his efforts after religious reform, and intrusted theological instruction in the new university of Halle to Franke, Breithaupt, and other disciples of S.—a matter that excited great irritation in the theological faculties of Wittenberg and Leipsic, which had formally censured as heretical no less than 264 propositions drawn from S.'s writings. S. died at Berlin, February 5, 1705, leaving behind him a reputation for piety, wisdom, and practical Christian energy, which all the excesses of the later pietists have not obscured. His writings are numerous; the chief are *Pia Desideria* (Frankf. 1675), *Das geistliche Priesterthum* (Frankf. 1677), *Christliche Leichenpredigten* (13 vols., Frankf. 1677), *Des thätigen Christenthums Nothwendigkeit* (Frankf. 1679), *Klagen über das verdorbene Christenthum* (Frankf. 1684), *Evangelische Glaubenslehre* (Frankf. 1688), and *Theologische Bedenken* (Halle, 5 vols., 1700—1721). See Hossbach's *Phil. Jak. S. und seiner Zeit* (2 vols., Berl. 1828); Thilo's *S. als Katechet*

(Stutt. 1841); and Wildenhalm's *Phil. Jak. S.* (Leip. 1842—1847).

SPENSER, EDMUND, one of the chief literary ornaments of the great Elizabethan period, was born in London in the year 1553. There is some ground for supposing him to have been of good family connection; but inasmuch as of neither of his parents is any thing whatever known, the evidence of this is precarious. In 1569, he went to Pembroke Hall, Cambridge, in the humble capacity of sizar, in itself a sufficient proof that whatever his family, the gifts of fortune were deficient. At Cambridge, he remained several years, becoming Bachelor of Arts in 1572, and Master in 1576. After leaving college, he went to live with friends in the north of England. Of the detail of his life at this period, nothing is known further than that he busied himself with poetry, his first volume of which, *The Shephearde's Calendar*, was published in 1579. Its dedication to Sir Philip Sidney was the means of introducing him to that noble and kindly gentleman, who not only extended to him a generous patronage, but honoured him with his warm friendship. He seems for some time to have been domesticated with Sir Philip at Leicester House, from which he dates his moiety of the *Foure Epistles*, exchanged between him and Gabriel Harvey, and printed in 1580. Towards the end of this year, through the influence of Sidney's uncle, the Earl of Leicester, an appointment was procured for him as secretary to Lord Grey of Wilton, the queen's deputy in Ireland, whither he at once proceeded. About this time it was that he commenced his great work, *The Faery Queen*. His official duties must have been punctually and ably performed, as in 1586 we find his services rewarded by a grant from the crown of Kilcolman in the county of Cork, an estate of upwards of 3000 acres, on which he now went to reside. Along with this piece of good fortune, came the evil news to him of the death of his friend Sidney at Zutphen, an event which he musically bewails in the elegy entitled *Astrophel*. Subsequently, the place of Sidney, as at once his patron and friend, was in a measure supplied by Sir Walter Raleigh, who visited him in Ireland in 1590, took him along with him to England, and introduced him to the notice of Queen Elizabeth. His experiences as a suitor for court-favour seem not to have been specially of a pleasant kind, if we may judge from a passage in one of his works, in which a keen personal feeling of wrong and weary humiliation speaks out unmistakably. Documentary evidence exists, however, that a pension of £50 per annum was granted him by Queen Elizabeth; that it was ever paid, or paid with due punctuality, there seems considerable reason to doubt. That Elizabeth, along with her greater qualities, could exhibit on occasion an extreme meanness and stinginess, there is no reason to doubt whatever. What portion of S.'s after-life was passed in England, what in Ireland, we do not distinctly know. Nearly all we distinctly know of him henceforth is the date of his several publications. The first three books of *The Faery Queen*, issued on his arrival in England in 1590, were followed the year after by three more, and a collection of lesser pieces entitled *Complaints*, including *Mother Hubbard's Tale*, the *Tears of the Muses*, &c.; and in 1596, by four *Hymns*, so called, in which the Platonic doctrine of Beauty is elaborated in noble music. In 1596, he wrote his *View of Ireland*, a treatise full of sagacious observation and remark, which was only published long after in Dublin in 1633. Further than this, all record which survives to us of S. is summed in the facts, that in 1594 he was married to a woman whose very name has perished; that in 1598 he was made sheriff of Cork by the queen; and that in the course of the same year the deplorable calamity befel him, which shortly preceded, and, in part, may have caused his death. Tyrone's rebellion having broken out, his house at Kilcolman was sacked and burned by the rebels, he and his wife with difficulty escaping, whilst their youngest child perished in the flames. On January 15, 1599, his death took place in London. According to the account given by Ben Jonson to Drummond, he '*died for lake of bread.*' This is not likely to have been in the literal sense true, but it is scarce possible to evade the inference from it, as coming from one so likely to be well informed as Jonson, of a state of great wretchedness and destitution. He was buried by his own request near Chaucer in Westminster Abbey, at the expense of the Earl of Essex, who is said, in the account by Jonson, to have tendered him succour on his death-bed, though too late to be of any avail.

S. takes admitted rank as one of the very greatest of British poets; and his chief work, *The Faery Queen*, written in that stateliest of English measures, since known by the name of its inventor, tedious as it is in its allegory, and in much of its diction obsolete even when written, is a masterpiece of opulent genius. In the poetry of S., an ever-present seeking for and sense of beauty finds its fit expression and reflex in a fluent succession of sweet and various cadences; in breadth and splendour of pictorial effect, it has never, perhaps, been surpassed; such a lavish exuberance in detail as we find in it, has seldom been so combined with a total impression of chastened and majestic sobriety; and throughout it is pervaded by that atmosphere of moral wisdom and serenity which Milton reverently recognises in 'the sage and serious Spenser.'—See *Spenser and his Poetry*, by Prof. S. L. Craik (3 vols. 1845). The most complete edition of the poet's works is that by Todd (Lond. 8 vols. 1806); but a new edition, with glossary, notes, and life, by J. P. Collier, was announced in 1862.

SPENSE'RIAN STA'NZA. See METRE.

SPERMACE'TI is a waxy matter obtained from a cavity in the head of the whale, *Physeter macrocephalus*. See CACHOLOT. It is separated from the oil, in which it is originally dissolved, by boiling water, from which the spermaceti crystallises as it cools. It is then purified by being remelted in a weak solution of potash, and the impurities skimmed off, and it is finally melted again by the action of steam, and cooled slowly in moulds. Its specific gravity is 0·943; it is scarcely unctuous to the touch; does not melt under 100°, has little taste or odour, and occurs in pearly-white, glistening, translucent crystals. It was generally regarded by chemists as a palmitate or cetylate of oxide of cetyl; but according to Heintz, who has studied the fats and their allies more, perhaps, than any other living chemist, it contains four alcohols (which act as bases), united with lauric, myristic, palmitic, and stearic acids.

Spermaceti is an emollient and demulcent, and is hence a useful ingredient in cough mixtures. It is, however, chiefly used externally as an ingredient in various ointments. The *Spermaceti Ointment* of the Pharmacopœia consists of a mixture of spermaceti, white wax, and almond-oil.

SPERMATOZOA. See SUPPLEMENT in Vol. X.

SPEY'ER, also **SPEIER** (Fr. *Spires*), the capital of Rhenish Bavaria (the former Palatinate), and one of the oldest towns in Germany, stands at the influx of the Speyerbach into the Rhine, 14 miles south-west of Heidelberg, and 23 north of Carlsruhe. It is connected with Mannheim, and thence with the rest of Germany, by railway. The principal building is the cathedral (founded 1030), which contains the

tombs of numerous emperors of Germany. Since 1856, it has been wholly renewed, and is the grandest specimen of Romanesque architecture in Europe. It has a hall of Roman antiquities discovered in the Palatinate, and is adorned with thirty magnificent frescoes by Schraudolph.

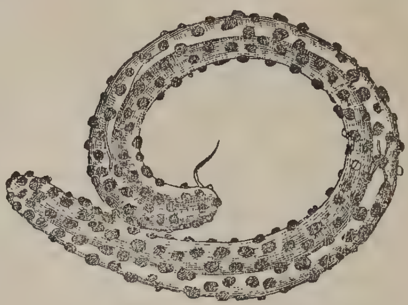
Except the cathedral and a ruined wall, the sole relic of the imperial palace in which twenty-nine diets were held—at one of which (1529) the Reformers made their famous 'protest,' and got for themselves the name of Protestants (see PROTESTANT)—S. does not contain a single ancient building. This is owing to the fact, that in the Orleans Succession War—well called by the Germans the *Mordbrenner Krieg*—during which the whole Palatinate was savagely wasted, S. was taken by the French, its inhabitants driven out, and the city blown up with gunpowder, and burned to the ground. Only the cathedral resisted the barbarous efforts to mine it. Everything else was reduced to rubbish, and for long years the noble old pile overlooked nothing but a melancholy waste of ruins. In 1794, it was wasted by the French under Custine, and has never recovered from these calamities. S. manufactures vinegar and tobacco, and has some transit-trade on the Rhine. Pop. 14,806, of whom about one-third are Catholics.

S. is the *Noviomagus* of the Romans, and was the capital city of the Nemetes, a German people. S. was probably the native name from the first, for in some of the later Roman notices it is called *Civitas Nemetum, id est Spira.*

SPE'ZIA, a city of Northern Italy, province of Genoa, and 60 miles south-east of the city of that name. Pop. 24,127. It is situated near the inner point of the gulf of Spezia. The gulf is formed by the bifurcation of a spur of the Apennines, and is 3½ miles long, and 3 miles broad; its western shore is indented by many coves or creeks, five of which—Porto-Venere, La Castagna, the Varignano (the Quarantine station), Grazie, and Panigaglia—are so deep that large men-of-war may be moored in them. The Emperor Napoleon I. recognised the importance of this gulf, and at one time designed, it is said, to make it the chief naval station of his empire in the Mediterranean. Now, the Italian government has made it the station for its ships of war, and operations have been already begun for making it the great arsenal of the state. The scenery of the gulf is very beautiful, and the mildness of its climate was famous in ancient times, when it was known as the Gulf of Luna. The soil produces olives, excellent wines, fruits, &c., and the town has become within recent years a much frequented watering-place. There are numerous foreign consulates. Steamers perform the voyage from S. to Genoa in eight hours. On the eastern side of the gulf stands Lerici (q. v.).

SPE'ZZIA (the ancient *Tiparenos*), a small Greek island at the entrance to the Gulf of Nauplia. Pop. 9400. The island is unfruitful, and its people are engaged chiefly in commercial pursuits. The town of S., on the north coast, has little more than 3000 inhabitants.

SPHÆRULA'RIA, a very remarkable nematode, or round worm, which exists as a parasite in various species of bees. The female is almost an inch in length, has a nearly uniform diameter of $\frac{1}{16}$th of an inch, is of a whitish colour, is bluntly pointed at each end, and is covered with numerous (about 800) small button-like projections—a peculiarity to which it owes its name. There is neither mouth, œsophagus, intestine, nor anus, and the whole animal consists of little more than an elongated mass of fatty tissue and reproductive organs, which in full-grown individuals contain ova in various stages of development. Although the female was discovered in 1836 (by Leon Dufour), it was not until January 1861 that the discovery of the male was announced by Mr Lubbock in his memoir on this parasite in



Sphærularia bombi; Male and Female:
Magnified 9 diameters. The male is seen as a thread-like appendage attached to the extremity of the female.—From Cobbold's *Entozoa.*

The Natural History Review. The male is more than 28,000 times smaller than the female, which accounts for its having been previously overlooked. It is frequently found sexually united to the female in the same manner as occurs in *Sclerostoma syngamus* (q. v.), the parasite which gives rise to the *Gapes* in various birds.

SPHA'GNUM, a genus of Mosses, whose spore-case is an urn closed by a deciduous lid, and its brim toothless, the calyptra irregularly torn. Several species are natives of Britain, and are common in bogs, from which they derive their popular name, BOG MOSS. They are remarkable for the whitish colour of their leaves. They are very elegant plants. They often grow in considerable masses, absorbing water like a sponge, but becoming friable when dry. They contribute much to the formation of peat. Gardeners employ them in preference to other mosses for covering the roots of plants and keeping them moist, as they have in a high degree the property of absorbing moisture from the atmosphere. They have been used as food in barbarous countries, but are very slightly nutritive. The cells of the leaves are remarkable for their spiral structure, and for large pores in their sides.

SPHE'GIDÆ, or SPHECIDÆ, a family of hymenopterous insects, winged in both sexes, and much resembling bees or wasps in general appearance. They are solitary in their habits. Many of them burrow in sand, and are known as *Sand-wasps.* They are extremely active and restless, and may be seen running about on sandhills, with their wings in constant motion. Some of them carry spiders, and others caterpillars, into their burrows, as food for their larvæ, placing them there when the egg is laid, and stinging them so as to render them torpid, without killing them. They display wonderful energy and perseverance in dragging the spider or caterpillar to the burrow. They are mostly tropical insects, but some species are found in Britain.

SPHE'NOID BONE (Gr. *sphēn*, a wedge, and *eidos*, form) is situated at the anterior part of the base of the skull, and articulated with all the other cranial bones, which it wedges firmly together. It somewhat resembles a bat with its wings extended, and hence was termed the *Os vespertilionis.* It is divisible into a body, the greater and lesser wings, and various processes. The greater wings present three surfaces: a superior or cerebral surface, forming part of the floor on which the brain rests; an

anterior surface, which assists to form the outer part of the orbit of the eye; and an external surface with a rough ridge, giving attachment to the external

The Upper or Cerebral Surface of the Sphenoid Bone :

1, The olivary process; 2, the ethmoidal spore; 3 and 4, the lesser and greater wings on the left side; 6, the extremity of left pterygoid process; 7, the foramen for the optic nerve; 10, the sella turcica on which the petuitary gland rests; 12, the basilar portion of the bone, joining with the occipital; 13, part of the sphenoidal fissure which separates the greater from the lesser wings, and transmits the 3d, 4th, the ophthalmic division of the 5th, and the 6th nerves, with the ophthalmic vein; 14, the foramen rotundum, transmitting the second division of the 5th nerve; 15, the foramen ovula, transmitting the third division of the 5th nerve; 16, the foramen sponosum for the passage of the middle meringeal artery.

pterygoid muscle, one of the most powerful muscles of mastication. The second, third, fourth, fifth, and sixth cranial nerves emerge from the cranial cavity through foramina in this bone. Although considered in human anatomy as a single bone, it may be regarded as composed of several bones, which, after a time, unite with one another, as the basi-sphenoid, the pre-sphenoid, the ali-sphenoid, and the orbito-sphenoid bones.

SPHERE, a regular solid figure, every point of whose surface is equally distant from its centre; and whose outline is traced by a circle revolving round its diameter. All sections of a sphere by a plane are necessarily circles, and all sections by planes passing through the centre, or by planes cutting the sphere at equal distances from the centre, are equal. The former sections are called *great*, and the latter *small, circles.* Small circles may vary in size between a mere point and a great circle, approaching either limit as nearly as we please. The surface of a sphere is equal to that of four of its great circles, or (taking x for the radius of the sphere) to $4\pi x^2$; and its volume to that of a cone whose altitude is twice that of the sphere, or $4x$, and whose base is a great circle of the sphere, the formula for it being $\frac{4x}{3} \times \pi x^2$, or $\frac{4}{3}\pi x^3$. The most remarkable geometrical property of the sphere is the relation which its surface and volume bear to those of the 'circumscribing' cylinder (i. e., a cylinder whose length and diameter of each end are each equal to the diameter of the sphere, and in which, therefore, the sphere will be exactly contained. The concave surface of such a cylinder is exactly equal to the surface of the sphere; and not only so, but if a section parallel to the base of the cylinder be made through both cylinder and sphere, the curved surfaces of the portions cut off are equal, whether such portion be cut off from one end or be intercepted between two parallel sections; it follows from this that the curved surface of any section of a sphere with parallel ends is equal to the product of the circumference of a great circle of the sphere by the height or thickness of the section, and that the curved surfaces of all sections of a sphere are proportional to the thickness of such sections. The volume of the sphere, also, is equal to two-thirds of that of the circumscribing cylinder.

SPHE'ROGRAPH, a simple and exceedingly efficient instrument for the mechanical solution of such problems in spherical trigonometry as navigation, geography, &c. present, was invented in 1856 by Mr Stephen Martin Saxby, R.N. It consists of two circular pieces of paper, the whole of the under and the rim of the upper being made of stout card-board, and the interior portion of the upper one of strong transparent tracing-paper; these two circles are attached by a pin through their common centre, the pin being made to work in an ivory collar, so as to prevent any lateral motion of either circle. Round the pin as centre, equal circles are drawn, one on each sheet; each circle is then filled in with lines representing meridians and parallels according to the stereographic projection, and the instrument is completed. As one of the chief uses of the spherograph is to shew the course, distance, and differences of latitude and longitude in 'Great Circle Sailing' (q. v.), we shall give a problem of this sort in illustration of the working of the instrument. Fig. 1 represents the appearance presented by the spherograph when the two poles are separated from each other by an angular distance of 40°; the lines drawn on the under circle (represented by *dotted lines* in

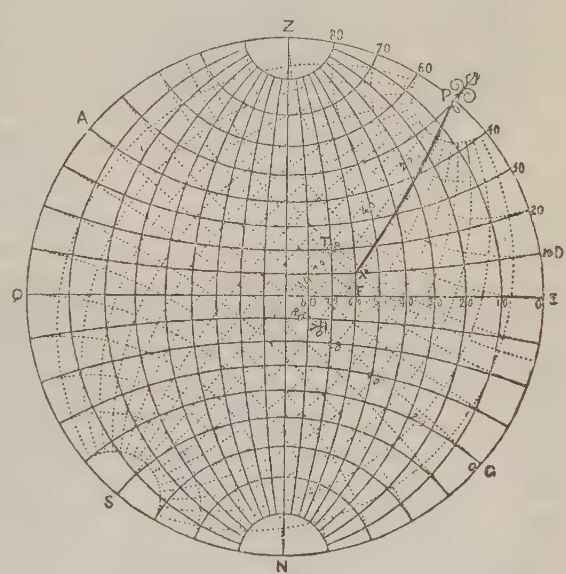


Fig. 1.

the fig.) shewing through the transparent paper which forms the upper circle, on which the continuous lines are delineated. Suppose, then, that a ship is in lat. 50° N., long. 20° W., and is bound for a point in lat. 10° N. and long. 80° W., and that its great circle track, &c., are required: let P, the pole of the under circle, represent the place of the ship (the circle ZPD always representing the meridian of the point of departure, and the upper circle, whose pole is Z, representing the earth's hemisphere), which is done by turning the upper circle till P appears at lat. 50° N.; X represents the point to be

arrived at, and consequently PX, the arc of a great circle passing through P and X, is the great circle track, PD is the difference of latitude, EF the difference of longitude; the spherical angle XPD, measured by GH, an arc of a great circle, of which P is the pole, is the course; and the length of PX is measured by PT, the portion of PS which is cut off by a parallel of the under circle through X, in degrees. The data, then, being as above, we find by inspection of the instrument the difference of lat. = 40° S., the difference of long. = 60° W., the course = S. $72\frac{3}{4}$° W., and the distance = $63\frac{1}{3}$° = 3800 nautical miles. Besides the saving of time and labour by the use of this instrument—the whole work being the *setting* of the instrument, and then the reading off of the required elements—it is evident that the substitution of a mechanical solution for calculation greatly lessens the probability of error. It is found that spherographs of 5 inches radius give results of sufficient accuracy for all the purposes of the navigator.

All other spherical problems can be solved with equal facility by this instrument, but one more example will suffice. Let Z (fig. 2) now represent the

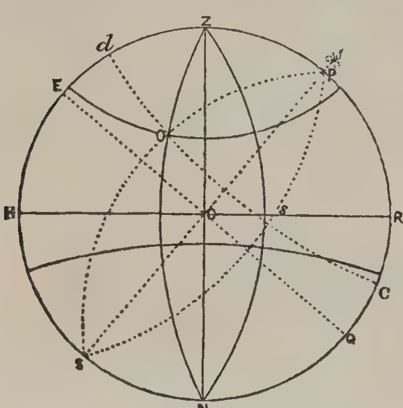

Fig. 2.

zenith of a place, ZHNR its meridian, P the north pole of the heavens; the other lines are then circles of declination, altitude, azimuth, and hour circles; and let O represent the place of the sun in given declination and altitude at a certain time. The instrument is now set by turning round the upper card till the point O (determined by its circle of declination and hour circle) on the under card falls upon the circle of given altitude on the upper card; then *d* is the sun's place at noon, H*d* being his meridian altitude, PR the latitude of the place, the angle RPS (measured in degrees along QE) the time of sunset, *ds* half the length of the day, *sc* half the length of the night, &c. The spherograph is also useful in finding latitude when the horizon is hid by fogs, right ascensions at night, and in correcting lunar observations; but for these purposes, spherographs are specially constructed, as some slight variations in the form given above are necessary.

SPHE'ROID is a species of Ellipsoid (q. v.), and is represented by the same equation. If an ellipse be made to revolve round one of its axes, the curved outline of the ellipse describes the spheroid. Should the major or longer axis be the axis of revolution, the spheroid is said to be *prolate* (Lat. *prolatus*, lengthened), but if the minor or shorter axis, *oblate*. The earth's axis of revolution which runs from pole to pole, being about 25 miles shorter than the longest or equatorial diameter, and these being at right angles to each other, the earth is considered as an oblate spheroid.

SPHEROI'DAL CONDITION of liquids is the name usually given to a series of very singular phenomena discovered by Leidenfrost, but first carefully investigated by Boutigny. Indeed, one, at least, of these phenomena has been popularly known for a very long time, being the foundation of the rough practical method of determining whether or not a flat-iron is so hot as to be likely to singe the linen to which it is to be applied. The test consists simply in letting a drop of water fall upon the iron; if it be not too hot, the drop spreads over the surface and evaporates. If it be too hot, the drop at once glances off the iron without wetting it.

The common experimental method of exhibiting the spheroidal condition is easily performed thus: A metallic disc, slightly concave, like a watch-glass, is heated by a lamp, and water is cautiously dropped on it from a pipette. If this be done before the disc is sufficiently heated, the water boils almost explosively, and is dispersed at once in vapour. But when the disc is hot enough, the water remains suspended, as shewn in the cut, *above* the surface; and the drop, when

small, takes nearly the form of an oblate spheroid. Various proofs have been given, though they are obviously unnecessary, that there is no contact in this case. Thus, if the disc be very nearly flat, light passes freely between it and the drop. Again, if one pole of a galvanic battery be connected with the disc, and the other be dipped into the drop, a galvanometer interposed in the circuit shews that no current passes. By heating the disc sufficiently, and dropping on the water very carefully, we may easily keep in the spheroidal state as much water as, if not more than, it could hold when cold. The explanation of the phenomenon is not yet quite clear; but there is no doubt that the radiant heat from the disc raises vapour so freely from the surface of the drop nearest it, as to interpose a cushion of dense and highly-heated vapour between them, on which the drop, as it were, floats; the pressure of the vapour balancing its weight. This is not, however, a quite complete explanation of the experiment, and it would require too much detail to examine it more closely. But the most curious fact connected with the experiment is, that the water does *not* boil. In fact, it evaporates so freely that the heat carried off from it, as latent heat, by the vapour which is constantly formed, keeps its temperature somewhere about 206° F. only. This suggests a curious experiment, which is found to succeed. *Boiling* water, dropped on a red-hot plate of metal, instantly assumes the spheroidal state, and is *cooled* six degrees below boiling.

It is not necessary that a metal plate be used—a watch-glass will suffice for the experiment; but *hot* water must be dropped on it, else the glass will crack.

Other liquids, and even some bodies which are solid at ordinary temperatures, can be easily brought into the spheroidal state—the lowest requisite temperature of the disc being dependent on the boiling point of the substance. Thus, while water has a temperature of 206° F. in the spheroidal state, the disc must have a temperature of 340° F. at least—for alcohol, these temperatures are 168° F. and 270° F.—for ether, 94° F. and 140° F. A good example of a solid entering this state is furnished by dropping crystals of iodine on a hot platinum disc.

It is not necessary that the disc should be solid; it is easy to obtain ether, and even water in the spheroidal state over the surface of hot oil—but

great care is required, as explosions are apt to occur, in which case the hot oil is freely thrown about.

Many cases of bursting of steam-boilers, otherwise apparently inexplicable, seem to be attributable to this condition of matter. Thus, if we suppose that the water-supply has run low, and the boiler has been overheated, it is conceivable that the contents may sometimes be in the spheroidal state. The addition of cold water, in such a case, would bring them suddenly *in contact with* the overheated metal, and large quantities of steam would be generated with violence.

A very singular experiment, the freezing of water on a red-hot plate, is easily performed by the help of this property of matter. Liquid sulphurous acid is so volatile as to have a temperature of 13° F. only, when in the spheroidal condition. As this is 19° under the freezing-point of water, if a little water be dropped into the spheroid of acid, it is at once frozen, and the pellet of ice can be dropped on the hand from the still red-hot plate.

Even mercury can be frozen by a similar process, but as much greater cold is required, the substance in the spheroidal state is a mixture of solid carbonic acid and ether.

The hand may be dipped for a short time with impunity into melted lead, and even into melted copper. The vapour, instantly raised from the moisture of the skin, prevents, so long as that moisture lasts, more than an endurable amount of radiant heat from reaching the hand, and also prevents direct contact. It is probable that a knowledge of some forms of this phenomenon, in old days, was employed by priestcraft for the purpose of protecting, when it was desirable to do so, the victims of the Ordeal (q. v.) by fire.

The phenomenon may easily be reversed. Thus, a red-hot silver ball, dropped into a vessel of water, is seen to glow for some time, till it has so far cooled, that the water comes into contact with it, when we have, as in the other form of the experiment, an immediate and violent formation of vapour. The success of this experiment is greatly aided by the addition of some strong ammonia to the water.

SPHINCTER MUSCLES (Gr. *sphinktēr*, that which binds tight) are circular bands of muscular fibres, whose function is to antagonise the expellent action of certain viscera, especially the bladder and the lower part of the intestinal canal. It is to the presence of these muscles that the higher animals owe the power of retaining for a considerable period the excrementitious matters collected in the bladder and rectum, and of discharging them at intervals, the sphincter muscles being like those engaged in the process of respiration, mainly, but not entirely under the control of the will. Under certain conditions, however, the necessity for expelling the contents of these viscera becomes so urgent that the sphincters lose their ordinary voluntary power.

SPHINX, a Greek word, signifying the Squeezer or Strangler, applied to certain symbolical forms of Egyptian origin, having the body of a lion, a human or an animal head, and two wings attached to the sides. Various other combinations of animal forms have been called by this name, although they are rather griffins or chimæras. Human-headed Sphinxes have been called androsphinxes; one with the head of a ram, a criosphinx; with a hawk's head, a hieracosphinx. The form, when complete, had wings added at the sides; but these are of a later period, and seem to have originated with the Babylonians or Assyrians. In the Egyptian hieroglyphs, the Sphinx bears the name of *Neb*, or Lord, and *Akar*, or Intelligence, corresponding to the account of Clemens, that these emblematic figures depicted intellect and force. The idea that they allegorised the overflow of the Nile when the sun was in the constellations Leo and Virgo, appears quite unfounded. In Egypt, the Sphinx also appears as the symbolical form of the monarch considered as a conqueror, the head of the reigning king being placed upon a lion's body, the face bearded, and the usual dress-drapery being suspended before it. Thus used, the Sphinx was generally male; but in the case of female rulers, the figure has a female head, and the body of a lioness.

The most remarkable Sphinx is the Great Sphinx at Gizeh, a colossal form, hewn out of the natural rock, and lying 300 feet east of the second pyramid. It is sculptured out of a spur of the rock itself, to which masonry has been

View of the Great Sphinx during the excavations of Caviglia, 1816.
From Colonel Vyse's *Pyramids of Gizeh.*

added in certain places, to complete the form, and measures 172 feet 6 inches long by 56 feet high. Immediately in front of the breast, Caviglia found, in 1816, a small naos, or chapel, formed of three hieroglyphical tablets, dedicated by the monarchs Thothmes III. and Ramesses II. to the Sphinx, whom they adore under the name of Haremakhu, or Harmachis, as the Greek inscriptions found at the same place call it—i. e., the Sun on the Horizon. These tablets formed three walls of the chapel; the fourth, in front, had a door in the centre, and two couchant lions placed upon it. A small lion was found on the pavement, and an altar between its fore-paws, apparently for sacrifices offered to it in the time of the Romans. Before the altar was a paved esplanade or dromos, leading to a staircase of thirty steps placed between two walls, and repaired in the reigns of M. Aurelius and L. Verus, on the 10th May 166 A.D. In the reign of Severus and his sons, 199—200 A.D., another dromos, in the same line as the first, and a diverging staircase, were made, while some additions were found to have been made to the parts between the two staircases in the reign of Nero. Votive inscriptions of the Roman period, some as late as the 3d c., were discovered in the walls and constructions. On the second digit of the left claw of the Sphinx, an inscription, in pentameter Greek verses by Arrian,

probably of the time of Severus, was discovered. Another metrical and prosaic inscription was also found. In addition to these walls of unburnt brick, galleries and shafts were found in the rear of the Sphinx, extending northwards. The excavations, however, of M. Mariette, in 1852, have thrown further light on the Sphinx, discovering the peribolos, or outer wall that encircled it; that the head only was sculptured; and that the sand which had accumulated round it was brought by the hands of man, and not an encroachment of the desert; also that the masonry of the belly was supported by a kind of abutment. To the south of the Sphinx, Mariette found a dromos, which led to a temple built, at the time of the fourth dynasty, of huge blocks of alabaster and red granite. In the midst of the great chamber of this temple were found seven statues, five mutilated and two entire, of the monarch Shaf-ra or Cephren, made of a porphyritic granite. They are fine examples of ancient Egyptian art. While the beauty and grandeur of the Great Sphinx have often attracted the admiration of travellers, its age has always remained a subject of doubt; but these later discoveries prove it to have been a monument of the age of the 4th dynasty, or contemporary with the pyramids.

Besides the Great Sphinx, avenues of Sphinxes have been discovered at Saqqarah, forming a dromos to the Serapeium of Memphis, and another dromos of the same at the Wady Esseboua. A Sphinx of the age of the Shepherd dynasty has been found at Tanis, and another of the same age is in the Louvre; and a granite Sphinx, found behind the vocal Memnon, and inscribed with the name of Amenophis III., is at St Petersburg. An avenue of criosphinxes has been found at Karnak. These are each about seventeen feet long, and of the age of Horus, one of the last monarchs of the 18th dynasty. Various small Sphinxes are in the different collections of Europe, but none of any very great antiquity.

The Theban Sphinx, whose myth first appears in Hesiod, is described as having a lion's body, female head, bird's wings, and serpent's tail, ideas probably derived from Phœnician sources, which had adopted this symbolical form into the mythology from Egypt. She was said to be the issue of Orthos, the two-headed dog of Geryon, by Chimæra, or of Typhon and Echidna, and was sent into the vicinity of Thebes by Juno, to punish the transgression of Laius, or, according to other accounts, by Bacchus, Mars, or Pluto. See Œdipus. The Sphinx was a favourite subject of ancient art, and appears in bas-reliefs, on medals of Chios and other towns, and often as the decorations of arms and furniture. In Assyria and Babylonia, representations of Sphinxes have been found, and the same are not uncommon on Phœnician works of art.

SPHINX. See Hawk-moth.

SPHYGMOGRAPH. See Supp. in Vol. X.

SPHYRÆ'NIDÆ, a family of fishes included by Cuvier in *Percidæ*, but having the ventral fins far behind the pectorals, and the bones of the pelvis quite detached from those of the shoulder. The form is elongated; there are two dorsal fins; the scales are small and cycloid; the mouth very large, with strong sharp teeth. The species are found in the Mediterranean and in tropical seas. Some attain a large size, as the Barracouda, or Barracouda Pike (*Sphyræna barracouda*), an inhabitant of the tropical parts of the Atlantic Ocean, which is scarcely less formidable than the White Shark. It is, however, held in considerable estimation as an article of food, but at some seasons of the year becomes unwholesome. It is a beautiful fish, of a rich green colour above, and white beneath. The Becuna (*S. vulgaris*) is also valued as an article of food, and its scales and air-bladder yield a substance used for making artificial pearls.

SPICCA'TO (Ital. separated), a musical term, indicative, like Staccato (q. v.), of a distinct and detached mode of performance. Its usual application is to music for bowed instruments, where it implies that each note is to have a bow distinct from that which precedes or follows it.

SPICE ISLANDS. See Moluccas.

SPICES (Lat. *species*, kinds; in later Latin, kinds of goods, or produce in general; and then, the most highly prized kind of goods, the aromatic productions of the East), aromatic and pungent vegetable substances, used as condiments and for flavouring food. They are almost exclusively the productions of tropical countries. In ancient times, and throughout the middle ages, all the spices known in Europe were brought from the east; and Arabia was regarded as the land of spices, but rather because they came through it, or were brought by its merchants, than because they were produced in it, for they were really derived from the further east. They owe their aroma and pungency chiefly to essential oils which they contain. They are yielded by different parts of plants; some, as pepper, cayenne pepper, pimento, nutmeg, mace, and vanilla being the fruit or particular parts of the fruit; whilst some, as ginger, are the root-stock; and others, as cinnamon and cassia, are the bark. Tropical America produces some of the spices, being the native region of cayenne pepper, pimento, and vanilla; but the greater number are from the East Indies.

SPIDER (*Aranea*), a Linnæan genus, now divided not only into many genera, but into many families, and constituting a section (*Araneida*) of the class *Arachnida*, and order *Pulmonaria*. The species are very numerous, and are found in all parts of the world, but most abundantly in tropical countries, which also produce the largest species, some of them capable of making very small birds, and not merely insects, their prey (see Bird-catching Spider). The *cephalothorax*, formed by the combination of the head and thorax into one piece, is covered with a kind of horny buckler, generally of an oval form; the abdomen is attached to it by a short stalk, and is generally soft and tumid. Each of the eight legs consists of seven joints, the last armed with two hooks, which are commonly toothed like a comb. The *frontal claws*, commonly called *mandibles*—which do not, however, correspond to the mandibles of insects, and move in an entirely different direction, up and down—are terminated by a sharp movable hook, which has near its extremity a small slit for the emission of a venomous fluid secreted in a gland of the previous joint. The *maxillæ* are two in number, and between them is an organ called the *tongue*, forming part of the external apparatus of the mouth. The maxillæ are the basal joints of the *palpi*, which resemble very small legs, and are often terminated in the females by a small hook, but in the males by complicated and curious appendages, characteristic of the different genera and species. Spiders have generally eight eyes, the relative position of which varies remarkably in the different families and

genera. A few species have only six eyes, and a very small number have only two. The upper surface of the abdomen generally exhibits a number of impressed spots, most conspicuous in those kinds which have a smooth naked skin. The pulmonary orifices are either two or four in number, and are situated near the base of the abdomen. Near the nus are several *spinnerets*, small protuberances,

Position of Spider when attached to a thread of web, and spinning apparatus highly magnified.

pierced at the extremity with a multitude of minute orifices, from which threads of extreme tenuity are produced, all these threads combining to form one thread of the *web*. The substance which exudes from the spinnerets is glutinous, and immediately dries into thread on coming in contact with the air. It is elaborated in reservoirs, which terminate in intestine-like tubes. All spiders have spinnerets, and produce threads, although all do not use them for the same purposes; for they differ very much in their habits: some employ their webs in order to catch their insect prey, whilst others depend for the capture of their prey on their powers of running and leaping; and some weave for themselves habitations, in which they live, whilst others select holes and crevices as their places of abode. Almost all spiders envelop their eggs in silken cocoons, which some of them tear open when the young are hatched; they are attentive to their young, some carrying them for a time on their back, whilst some carry the cocoons or egg-cases beneath their breast, and others carry them attached to the extremity of the abdomen. Nearly 2000 eggs have been found in a single cocoon, and the young, when set free, may be seen swarming over the body of the mother, so as almost to conceal her from view. The female S. is in many of the species, much larger than the male, and a very remarkable danger attends the amatory approaches of the latter, as, if they are not favourably received, he is not uncommonly killed and eaten on the spot. Spiders are very pugnacious, and in their combats often sustain the loss of limbs; but, like crustaceans, they possess the power of repairing this loss. Like them also, they change their skin frequently during their growth; but they undergo no proper transformation. There is much similarity of form among all the multitude of kinds. Many of them exhibit very brilliant and beautiful colours, among which are some of the British species, to be found in fields and moors, although the Common House S. (*Aranea domestica*) is of very unattractive appearance.

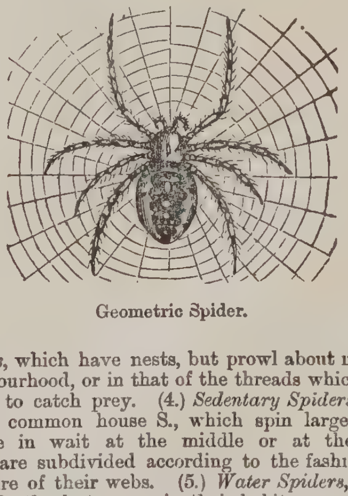
All spiders kill the insects and other small creatures on which they prey by means of their venomous mandibles, and the bite of a house S. is quickly fatal to a house-fly. The bite of the larger species is dreaded even by man, being very painful, and not only producing much inflammation and swelling but often much fever. Death has been known to ensue.

Spiders' webs have long been in high repute for staunching wounds. Threads of this material are also employed for the cross-wires of astronomical telescopes. Textile fabrics have been made of it, but only as articles of curiosity.

Spiders have been arranged by Walckenaer in five principal groups, distinguished by their habits. (1.) *Hunting Spiders*, which incessantly run about in the vicinity of their abode in quest of prey, some of them weaving silken tubes, in which they dwell, others hiding in fissures; some remarkable for the swiftness with which they run, others for their power of leaping in order to seize their prey. Some of them are of large size. Livingstone mentions a South African one which can leap a distance of one foot. A small one is common on windows in Britain in summer, and, when leaping, avoids the danger of falling from the window by suspending itself at the same moment by a thread. (2.) *Wandering Spiders*, which have no fixed residence, have the power of running sideways or backwards, and throw out threads to entrap prey, but do not weave them into

Various species of Spiders.

regular webs. Some of them live among plants, and place their egg-cases on leaves, the edges of which they bind together with their silk. (3.) *Prowling*



Geometric Spider.

Spiders, which have nests, but prowl about in their neighbourhood, or in that of the threads which they spread to catch prey. (4.) *Sedentary Spiders*, such as the common house S., which spin large webs, and lie in wait at the middle or at the side. These are subdivided according to the fashion and structure of their webs. (5.) *Water Spiders*, which resemble the last group in their habits, except that they live in water, generally among the stems and

eaves of aquatic plants, where they construct their webs. A very interesting species, one of the most interesting possible inmates of an aquarium, is the Common Water S. (*Argyroneta aquatica*) of Britain, not unfrequently to be found in deep ditches and ponds in some parts of England. It is of a brownish colour, densely covered with hairs, which are of great importance in its economy, entangling air, which the animal carries down with it into the water, to supply its pulmonary sacs; for the water spiders all breathe by the same kind of organs as their terrestrial congeners. The eggs of the water S. are attached to the leaves or stems of plants under the surface of the water, and are protected by a dome-shaped web, so close in its structure as to retain the air which is brought into it, and in which the S. itself lives, bringing down air on its furred body till the dome is filled. The entrance is from below.—Many of the nests of other kinds of S. are extremely curious structures, as that of the Clotho (q. v.), and that of the Trap-door S. (*Cteniza nidulans*) of the West Indies, which makes for itself a

Trap-door Spider (*Cteniza nidulans*):

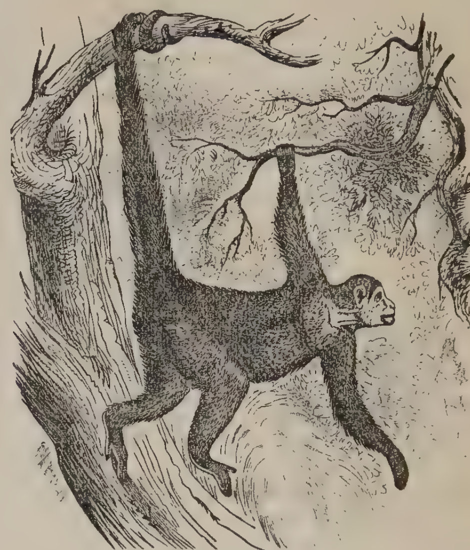
burrow in the ground, lines it with silk, and places at the mouth a perfectly circular door made of alternate layers of earth and web, fitting the entrance exactly, and with a silken hinge.

SPIDER FLY (*Ornithomyia*), a genus of dipterous insects, closely allied to the Forest Fly (q. v.), but the claws of the tarsi having three instead of two teeth; and the species are parasitical on birds, never on quadrupeds. *O. avicularia* frequently infests the common fowl, the blackcock, and other birds in Britain. It is greenish-yellow, with smoke-coloured wings.

SPIDER MONKEY, a name often given to species of the genus *Ateles*, small American monkeys, on account of their very long, slender, inelegant limbs. The tail is very long, and not only prehensile in the highest degree, but endowed with a wondrous sensitiveness of touch. These monkeys display great intelligence. It is their common practice to break nuts by means of stones; and a tame one which Dr Gardner carried with him in his travels in Brazil, used to try a larger stone, if the first did not serve its purpose, and even to take it up in both paws, and dash it upon the nut, jumping quickly out of the way to avoid injury to its own toes. This animal generally rode on the back of a large mastiff and in descending a steep hill, would curl its tail



Spider Monkey.

round the root of the mastiff's tail, to make its seat secure.

SPIGE'LIA, a genus of plants of the natural order *Loganiaceæ*, having a calyx glandular inside, a long slender valvate corolla, long filaments, and a capsule of two *cocci*, splitting around at the base.—*S. Marilandica*, often called WORM GRASS and CAROLINA PINK, is a native of the southern United States of America, a perennial plant with a simple quadrangular stem. The root (PINK ROOT) is purgative, narcotic, and poisonous, but is a powerful vermifuge, and is very commonly employed in the United States.—*S. Anthelmia*, an annual, native of tropical America, with very small purplish flowers, in spike-like racemes, possesses similar properties. The efficacy of both is, however, impaired by keeping; and they are apt to produce unpleasant symptoms when used as medicines. Other species are also known as poisons.

SPIKE, in Botany, that kind of inflorescence in which sessile flowers, or flowers having very short stalks, are arranged around an axis, as in the greater plantain, common vervain, common lavender, and some species of sedge. In rye, wheat, barley, darnel, and many other grasses, there is a sort of compound spike, that is, the flowers or fruits are arranged together in spikelets, upon short stalks, which again surround the top of the culm in the form of a spike. The catkin, the spadix, and the cone may be regarded as varieties of the spike.

SPI'KENARD, or NARD (Gr. *Nardos*), a perfume highly prized by the ancients, and used both in baths and at feasts. It was brought from India and was very costly. The 'ointment of spikenard' (John xii. 3) was probably an oil or fat, impregnated with the perfume. The plant which produces it has been ascertained by the researches of Sir William Jones and Dr Royle to be the *Nardostachys jatamansi*, the Jatamansi of the Hindus, a small plant of the natural order *Valerianaceæ*, a native of the mountains of the north of India, and found at least as far south as the Deccan

It grows on the Himalaya to an elevation of 18,000 feet, and its roots are a favourite perfume in Tibet and Nepaul. The ladies of Nepaul use oil in which the root has been steeped for perfuming their hair. The odour is not, however, generally agreeable to Europeans. The root, which is from three to twelve inches long, sends up many stems, with little spikes of purple flowers, which have four stamens.—The name spikenard was given by the ancients to perfumes used as substitutes for the true or Indian spikenard, some of which were derived from the roots of plants of the same natural order, the kind called Gallic or Celtic spikenard from those of *Valeriana Celtica* and *V. saliunca*, which are still used in the East for perfuming baths; and that called Cretan spikenard from those of *V. Italica*, *V. tuberosa*, and *V. phu*. All of these grow on the Alps and other mountains of the south of Europe, and the peasantry of Styria and Carinthia collect them from rocks on the borders of perpetual snow. They are tied in bundles, and sold at a very low price to merchants, who sell them at a great profit in Turkey and Egypt, from which they are partly transmitted even to India. About sixty tons are annually exported from Trieste.

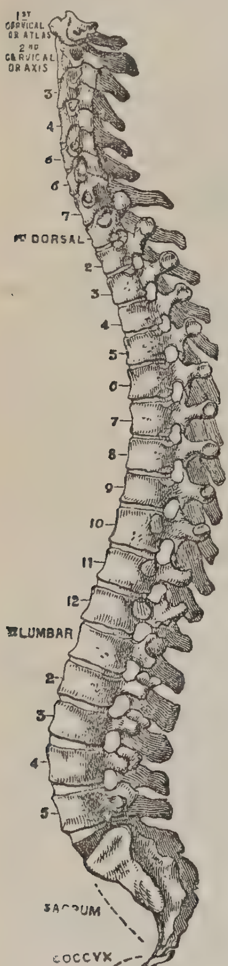
SPIKING is the operation of rendering a cannon useless without the expenditure of much time and labour. It is resorted to by troops compelled to abandon their own ordnance, or unable to remove pieces of the enemy's which they have captured. The process consists in driving a nail or spike into the vent or touchhole. To remove it, it is recommended, if an iron gun, to load with double charge and double balls, and to fire by a train laid through the muzzle. This is supposed to loosen the spike. If the gun be of brass, a few drops of sulphuric or nitric acid on the touchhole will render it practicable to extract the spike. If these methods fail, nothing remains but the tedious process of drilling out the spike or boring a new vent.

SPI'NA BI'FIDA is a congenital malformation, occurring perhaps more frequently than any other except hare-lip, and arising like it from arrest of development. It may be regarded as a congenital hernia of the membranes of the spinal cord, through a fissure in the wall of the bony canal. A tumour is thus formed, which is usually of a roundish shape, varying in size from that of an egg to that of an adult head, lying in the middle line of the back, fluctuating, and adhering to the adjacent vertebræ either directly or by a pedicle. The usual termination of the disease is death. As the size of the tumour increases, fatal convulsions ensue; or the skin investing the tumour may ulcerate, and the contents escape, in which case palsy or convulsions produce death. Occasional cases are, however, recorded in which patients with this affection have survived till middle life. Active surgical treatment usually hastens death, and should only be resorted to in the most urgent circumstances. Moderate support by means of a hollow truss, or a well-padded concave shield, may tend to keep the disease stationary; and any interference beyond this is, in the great majority of cases, unadvisable.

SPI'NACH, or **SPINAGE** (*Spinacia*), a genus of herbaceous plants, of the natural order *Chenopodiaceæ;* diœcious, the male flowers consisting of a 4-parted perianth and four stamens; the female, of a 2—3-cleft perianth, and a germen with four styles; the perianth hardening around the fruit as it ripens; the fruit an achenium. COMMON S., or GARDEN S. (*S. oleracea*), is in general cultivation for the sake of its young leaves, which are a favourite and wholesome vegetable, either prepared by boiling, or by frying with a little butter. Two very distinct varieties are cultivated.—PRICKLY S., which has the leaves somewhat triangular and arrow-headed, and the fruit rough with prickle-like projections; and SMOOTH S., or ROUND S. (*S. glabra* of some botanists), with the leaves more round and blunt, and the fruit smooth. S. is an annual. Its stem rises to the height of from two to four feet; the male flowers are in long spikes, the female in clusters close to the stem. After the stem begins to be developed, the leaves become bitter, and unfit for use. This bitterness appears also at an earlier period in dry weather, or in poor soil; and the more luxuriantly that S. grows, the better it is. It is sown in spring, and is ready for use in a very short time; or it is sown in autumn, thinned out, and used early in spring. The smooth S. is very generally preferred for the former purpose, and the prickly kind for the latter; but a somewhat intermediate variety, called Flanders S., is now often used for both, being particularly esteemed for the large size of its leaves. The native country of S. is not well known, but is believed to be some part of Asia, as the plant was introduced by the Arabs into Spain, and thence diffused over Europe.—Another species (*S. tetrandra*) is cultivated, and much esteemed, in India.—The name S. is also given to a number of other plants of very different botanical characters, but which have the same bland and nutritious qualities, and are used in the same way.—NEW ZEALAND S. is *Tetragonia expansa*, a plant of the natural order *Mesembryaceæ*, suborder *Tetragonieæ* (nat. ord. *Tetragoniaceæ* of Lindley), a trailing, succulent annual, spreading widely over the surface of the ground, and producing a great abundance of stalked ovate-rhomboid leaves. The young stems and leaves of this plant are much used in New Zealand, and have now come into very general use also in other parts of the world, as a kind of spinach. It is cultivated in the middle and south of Europe and in Britain, succeeding well even in Scotland with the slightest aid of a hotbed in spring.—PATIENCE DOCK, or GARDEN PATIENCE (*Rumex Patientia;* see DOCK) is called in Germany ENGLISH S., and was formerly much cultivated in England, but is now neglected.

SPINAL COLUMN, or **SPINE**, THE, is the most important and characteristic part of the skeleton of the highest animal sub-kingdom, which includes Mammals, Birds, Reptiles, Amphibians, and Fishes. In each of these classes, it is composed of a series of bones placed one above, or in front, of another, and called Vertebræ (q. v.); and hence, these animals, having this distinguishing characteristic in common, are all included in the term *Vertebrates*. The vertebræ vary greatly in number in different animals, and even in members of the same class, and the number have no apparent relation to the other organs of the animal. Moreover, in their shape, they differ extremely even in different parts of the same spine, in accordance with their special functions. In man, the number of vertebræ which collectively form the spinal column is 7 in the neck (cervical vertebræ), 12 in the back (dorsal vertebræ), 5 in the loins (lumbar vertebræ), all of which are capable of being detached from one another, and are termed *true* vertebræ; and 5 vertebræ ossified together, and forming the sacrum, and 4 or 5 similarly united forming the termination of the column, and constituting the bone called the coccyx, which are known as *false* vertebræ. However long or short the neck may be, every mammal has 7 cervical vertebræ, excepting the three-toed sloth, which has 9, and the sea-cow, which has 6. In the other regions of the spine, no such law exists. Each vertebra is attached to the two between which it

lies by numerous strong and more or less elastic ligaments, and between each pair of vertebræ there is interposed a lenticular disc of fibro-cartilage, which acts as a buffer. By these arrangements, the spinal column is rendered highly elastic, the communication of jars or shocks is prevented, and a very considerable general range of movement permitted, although the motion between any two adjacent vertebræ is slight. The elasticity of the column is further increased by the component vertebræ being arranged in curves, instead of being placed perpendicularly. The curves should be exactly in the antero-posterior direction, any well-marked lateral deviation from the perpendicular being abnormal; but a very slight lateral curvature with the convexity to the right may often be detected in the upper and middle parts of the back, and is supposed to be dependent on the more frequent use and greater strength of the right arm as compared with the left. From their position, they are termed the cervical, dorsal, lumbar, and pelvic curves. The dorsal and pelvic curves have their concavities in front, and thus enlarge the spaces in which the thoracic and pelvic viscera are contained; the two other curves are convex anteriorly, and thus afford support to the parts above them. The upper three curves are so arranged that their chords are in the same vertical line in the erect position of the body, and this vertical line corresponds with the line of gravity of the head. The cause of these curves is to be sought for partly in the shape of the vertebral bodies, and partly in that of the intervertebral substance. Amongst the uses of these curves, it may be mentioned (1) that they enable the spine to bear a greater vertical weight than it could otherwise maintain; it is calculated that nine times as great a vertical force is required to bend it as if it had been straight; (2) that they facilitate the movements of the body, especially in the act of running; and (3) that they are so disposed as to protect the cord in movements of the spine. Similar curves are seen in the spine of other mammals, though the degree of flexure is liable to great deviations. The lumbar curve, which has especial reference to the erect position, is always much less marked than in man.



Spinal Column.

The vertebral canal formed by the apposition of the spinal foramina, or neural arches (see SKELETON), and containing and protecting the spinal cord, varies in its size at different parts of the column. It is largest in its antero-posterior diameter in the neck and loins (measuring at the last lumbar vertebra ⅞ths of an inch), where the antero-posterior movements of the spine are greatest, and where the cord is least closely attached to the vertebræ; while in its lateral diameter it is greatest at the atlas, where it measures nearly an inch and a half. A transverse section of the canal is nearly circular through the greater part of the back. The intervertebral foramina through which the nerves emerge vary in shape and position in different parts, but are always of sufficient size to prevent injurious pressure on the nerves during movement of the spine; and in the dorsal region, which is the ordinary seat of angular curvature, the nerves are so protected by bony arches, that they may escape injury, even when the bodies of several dorsal vertebræ have been destroyed by ulceration.

SPINAL CORD OR MARROW, THE STRUCTURE AND FUNCTIONS OF. The spinal cord is that elongated part of the cerebro-spinal axis (see NERVOUS SYSTEM) which is contained in the spinal canal from the *Foramen magnum*, at the base of the skull, superiorly, to the first or second lumbar vertebra inferiorly, where it merges into the *Filum terminale*, which extends to the lower end of the sacral canal, and in no way differs structurally from the proper spinal cord, except that no nerve-roots are connected with it. The membranes by which it is protected from danger, and kept in its proper position, are described in the article NERVOUS SYSTEM. Its length varies from 15 to 18 inches, and it presents a difference in its diameter in different parts, there being an upper or cervical, and a lower or lumbar enlargement. In form it is a flattened cylinder. It is almost completely divided, along the median plane, by an anterior and posterior fissure, into two equal and symmetrical parts. The anterior fissure is more distinct and wider at the surface than the posterior fissure, but it only penetrates to about one-third of the thickness of the cord, while the posterior fissure extends to about half the thickness of the cord. The two halves are hence only united near the centre by a commissural band, which is traversed by the 'spinal canal' (fig. 2, *f*), extending downwards from the fourth ventricle (see BRAIN), and about one-hundredth of an inch in diameter. A posterior and an anterior lateral furrow (two shallow depressions, the latter being scarcely perceptible) further divide each half of the cord into a posterior, a lateral, and an anterior column; these two furrows corresponding with the lines of attachment of the posterior and anterior nerve-roots. The separation of the antero-lateral columns into the 'anterior' and the lateral columns (A, A, and L, L, in fig. 2), is made more obvious internally by the mode in which the gray or vesicular nervous matter (described and figured in the article NERVOUS SYSTEM) is arranged in relation

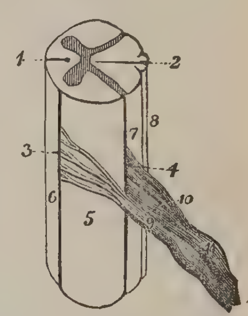


Fig. 1.—Side View of the Spinal Cord, shewing the Fissures and Columns.

1, anterior median fissure; 2, posterior median fissure; 3, anterior lateral fissure; 4, posterior lateral fissure; 5, lateral column; 6, anterior column; 7, posterior column; 8, posterior median column; 9, anterior root; 10, posterior root; and 11, ganglion of (12) a spinal nerve.—From Gray's *Human Anatomy*.

to the white or fibrous matter. Although the distribution of the gray matter differs considerably in different parts of the cord, it usually presents in a transverse section the form of two somewhat crescent-shaped masses, whose convexities are turned towards each other, and are connected by the gray commissure, while their cornua are directed towards the surface of the cord; the posterior peak on each side nearly reaches the posterior lateral furrow, while the anterior, though the larger cornu, does not approach quite so near

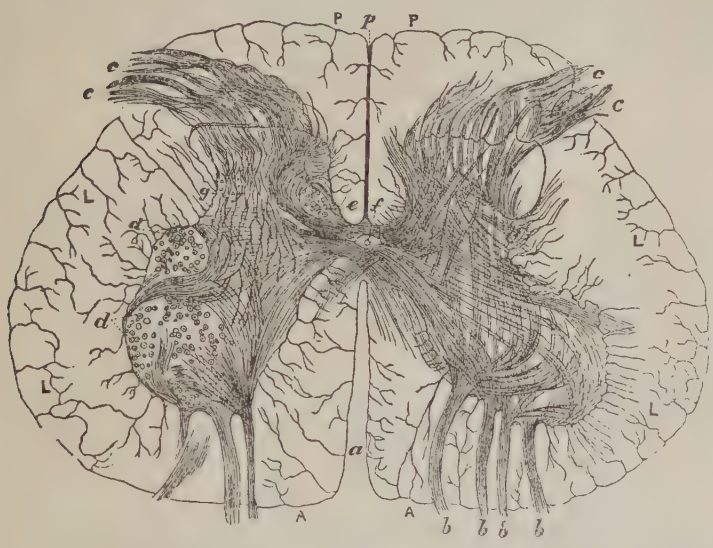

Fig. 2.—Magnified View of Transverse Section of the Spinal Cord through the middle of the Lumbar Enlargement: shewing, on the right side, the course of the Nerve-roots, and on the left, the position of the principal tracts of Vesicular Matter.

A, A, anterior columns; P, P, posterior columns; L, L, lateral columns; *a*, anterior median fissure; *p*, posterior median fissure; *b*, *b*, *b*, *b*, anterior roots of spinal nerves; *c*, *c*, *c*, *c*, posterior roots; *d*, *d*, tracts of vesicular matter in anterior column; *e*, tracts of vesicular matter in posterior column; *f*, spinal canal.—After J. L. Clarke.

the surface at the assumed anterior furrow. The enlargement of the cord in the cervical and lumbar region, where the great nervous plexuses are given off, is chiefly due to the increase, at those points, of gray matter, which is comparatively deficient in the interval between them. The white substance seems to increase regularly from the lower to the upper part of the cord; and this fact, as Dr Carpenter remarks, seems to indicate the probability that the longitudinal columns serve (as formerly supposed) to establish a direct connection between the encephalic centres and the roots of the spinal nerves. Careful microscopic investigation has revealed the fact, that the root-fibres of the spinal nerves run two very distinct courses in the substance of the cord; the first *transverse*, and the second *longitudinal*. The transverse fibres traverse the cord horizontally or obliquely, and appear to pass out in the other sets of roots connected with the same segment, either on its own or on the opposite side of the median fissure; while the longitudinal fibres in part connect the posterior roots directly with the posterior column without passing into the vesicular matter, but for the most part enter the gray matter, and emerge from it into the posterior column, or into the posterior part of the lateral column of the same or the opposite side. How far these longitudinal fibres run up or lown the cord, is undecided. It is probable that *some* of them are longitudinal commissures, serving to connect the nerve-roots of one segment of the cord with the vesicular matter of another above or below it, and it is possible that *all* are of this character, in which case the spinal cord will be the real centre of all the nerve-fibres connected with it.

In considering the functions of the spinal cord, we have to regard it in two distinct points of view—viz., in the first place, as a *conductor* of nervous force between the nerve-trunks and the brain; and in the second place, as an *independent nervous centre*. As a mere *conductor* of nervous force, its functions and behaviour are the same as those of a nerve-trunk; for, as Dr Carpenter observes, 'if it be divided, all the parts of the body which are solely supplied by nerves coming off below the point of section are completely paralysed, as far as regards sensibility and voluntary movement; no impressions made upon them having the least power to affect the consciousness, and no exertion of the will being able to determine contraction of the muscles. This state of *paraplegia*, which may be experimentally induced in animals, is frequently exhibited in man, as a result of injury or of disease that seriously implicates the spinal cord; and as it has been shewn that among the lower animals complete reunion of the cord may take place after complete division, as indicated by the entire restoration of its functional powers, and the complete redintegration of its structure, so have we reason to believe that a similar regeneration may take place, to a considerable extent, in man, this being marked by a gradual return of sensibility and power of voluntary movement in the lower limbs, which had been at first completely paralysed.'—*Human Physiology*, 6th ed., pp. 529, 530. There can be little doubt that the gray matter is essentially the conductor of *sensory* impressions, for if the anterior, posterior, and antero-lateral columns are divided as completely as possible, the gray substance remaining uninjured, the sensibility of the parts below is unaffected; while, conversely, if the gray substance is divided, while the white columns remain uninjured, sensibility is almost totally extinguished. M. Brown-Séquard, whose researches on the nervous system are of the highest importance, has shewn that the central portions of the gray substance are the most effective in the transmission of sensation. He likewise brings forward strong evidence to prove that there are special conductors in the spinal cord for the sensations of touch, pain, temperature, and muscular contraction, none of which can convey other sensations than their own. Notwithstanding its singular power of conducting sensory impressions, the gray substance is itself insensible. Amongst his other remarkable discoveries in connection with this subject, Brown-Séquard has found, that on dividing one-half of the spinal cord of an animal, not only is

anæsthesia (or loss of sensation) established on the opposite side of the body, but there is also produced a state of hyperæsthesia (or exalted sensibility) on the same side, which begins to appear a few hours after the operation, and continues in dogs for about 20 days, in cats about 14 days, and in guinea-pigs for many months, after which the sensibility falls below its usual standard. With regard to the conduction of *motor* impulses, there is great uncertainty. Considerable differences have been shewn to exist in the position of the motor tracts in different parts of the cord, and Brown-Séquard concludes from his experiments on the effects of section, that while in the dorsal region, all parts, except the posterior columns, are employed in the conveyance of the orders of the will to the muscles, in the upper part of the cervical region, most of these conductors are in the lateral columns and in the gray substance between these and the anterior column.

We have now to consider the spinal cord as an *independent nervous centre.* The simplest, and, at the same time, the most decisive evidence of the independent power of the spinal cord, is derived from the motion exhibited by the limbs of animals when irritation is applied to them after section of the cord at some point above the entrance of their nerves; the fact that these movements are reflected through the cord, and do not result from direct stimulation of the part irritated, being shewn by their complete cessation when the nerve-trunks are divided. Thus, if a frog be pithed by dividing the cord between the occipital foramen and the first vertebra, an unusual convulsion takes place while the knife passes through the nervous centre; but this quickly subsides, and if the animal be placed on the table, it will resume its ordinary position. It is quite unable to move by any voluntary effort; but if a toe be pinched, the limb is instantly drawn up, and seen to push away the irritating agent, and then draw up the leg again to the old position.

From these and other experiments, we may conclude (1) that the spinal cord, *in union with the brain,* is the instrument of sensation and voluntary motion to the trunk and extremities; and (2) that the spinal cord may be the medium for the excitation of movements, *independently* of volition or sensation, either by direct irritation of its substance, or by the influence of a stimulus conveyed to it from some surface of the trunk or extremities by its nerves distributed upon that surface.—For further information on this subject, the reader is referred to Todd and Bowman's *Physiological Anatomy and Physiology of Man,* 2d ed., vol. i. pp. 255—260, and 307—341; and Carpenter's *Human Physiology,* 6th ed., 1864, pp. 491—500, and 519—538.

SPINA'ZZOLA, a city of Southern Italy, province of Terra di Bari, 7 miles south of Minervino. Pop. 9924. The country around is very fertile, and produces grain in abundance.

SPINDLE TREE (*Euonymus*), a genus of plants of the natural order *Celastraceæ.* This order contains about 260 known species, all small trees or shrubs. —The genus *Euonymus* has a lobed capsule, and seeds surrounded by an aril, which in some of the species is remarkable for its brilliancy of colour. The Burning Bush, or Waahoo (*E. atropurpureus*), a native of the United States, chiefly of the northern parts, and the *E. Americanus,* or Strawberry Bush, of more southward regions, are very ornamental when in fruit, and the aril is of a fine orange colour. They are shrubs rather than trees. The wood of the *E. Europæus* is hard and fine-grained. It is used for the finer articles of turnery, and for skewers. It was formerly used for making musical instruments and for spindles, whence the name of the shrub. In Germany, the shoots are bored for tubes of tobacco-pipes.

SPINE, or THORN, in Botany, is a sharp-pointed projection of the wood of a stem or branch, and essentially differs from a Prickle (q. v.) in being connected with the wood, and covered with bark. A spine is, in fact, a branch arrested in its growth and modified. In some trees and shrubs, as in the sloe, branches which bear leaves often terminate in the form of a spine. Cultivation, or whatever tends to increase the luxuriance of a plant, diminishes the tendency to produce spines. The name spine is also given to the sharp extremities of the midrib of leaves, and to the sharp angular projections of the margin of hard leaves, as in the holly. In some plants, the stipules are metamorphosed into spines.

SPINE, CURVATURE OF THE. There are two perfectly distinct forms of curvature, viz., LATERAL CURVATURE—arising from weakness of the bones, ligaments, and muscles, and fearfully common in girls of the middle and upper classes, between the ages of 10 and 16—and ANGULAR CURVATURE (frequently known as POTT'S CURVATURE, or the MALADY OF POTT, in consequence of that eminent surgeon having been the first to describe its true nature), which consists of caries of the bodies of the vertebræ, and is by far the more serious affection of the two.

'*Lateral Curvature,* or *Distortion,* denotes deformity of the bones of the spine and chest; with corresponding change of the structures in relation to them. It is called "lateral," from the spine being curved sideways; and to distinguish it from "angular" deformity, in which the spine is directed from behind forward, owing to excavations in its forepart from caries.' The above definition is taken from Mr Shaw's article on this affection in Holmes's *System of Surgery,* vol. iv. p. 844, an article from which we have borrowed freely in relation to the symptoms and causes of the disease. The first thing that commonly attracts attention is a projection of one scapula, or an elevation of one shoulder, generally the right; the right shoulder and right side of the chest being unnaturally high and rounded, while on the left side, the shoulder is depressed, and the side of the chest concave. On examination, the spine is found to have acquired a spiral appearance, 'not unlike what might have been produced if it had been taken, when soft, at both ends by the two hands, and twisted as a washerwoman wrings a wet cloth.'—Shaw, *op. cit.* In advanced stages of the distortion, the dorsal curve increases abruptly to such an extent as to render it angular, the attending contortion being similarly abrupt. This condition gives rise to various changes, including a *humped* appearance, a great displacement of the ribs, a diminution of the cavity of the chest, and a proportionate wasting of the lung. In consequence of these physical changes, the patient can no longer walk in a simple and natural manner, but exhibits a halting, jerking, awkward gait.

The following may be noticed amongst the principal causes of lateral curvature: 1. The suppleness of the spine in the young, its structure being then more gristle than bone, and the column virtually immature. 2. Weakness of the muscles, which are seldom properly exercised in girls of the age and class in which this disorder occurs. This muscular debility is usually followed by deterioration of the bones and their ligaments, and this, apart from other obvious and direct bad effects, tends to make all the component parts of the spine —vertebræ and articulations—more prone to yield to the superincumbent weight, and to become

distorted. These evil results are increased by prolonged stooping. When we enter a school, shortly before the breaking up of the class, we usually find most of the pupils standing or sitting in a tired lounging position. They are instinctively relieving the pain of over-fatigue by throwing the weight on the insensible fibrous structures, and thus relieving the aching muscles. When such attitudes are long indulged in, the ligaments undergo a process of over-stretching, and a general looseness of the vertebral joints is the result. By standing on one leg, or, more correctly speaking, by throwing all the weight of the body on one foot, the body is kept upright with the least possible expenditure of muscular power. Hence, a weak and fragile girl is induced to adopt this position. Too long indulgence in this habit will, to a certainty (for anatomical reasons, into which we have not space to enter), aggravate existing curvature, and induce it, if it did not pre-exist.

However slight a curve in the spine of a young girl may be, it ought to be deemed of importance; for when the column inclines laterally even to a slight degree, the superincumbent weight ceases to be supported on the line of the vertical axis, and falls on the oblique processes of the side to which she leans; and these processes becoming rapidly diminished in length by absorption, induced by this abnormal pressure, general distortion rapidly commences. With regard to the final issue of a case, distortion beginning at the age of ten is more dangerous than at fourteen, because the disease runs a more rapid course in the younger cases. A cure is, for the same reason, more easily effected in the younger patient. If the patient's age be beyond sixteen, little can be done beyond checking the further progress of the deformity.

Before discussing the treatment of these cases, it is necessary to say a word regarding an important preventive measure. When a girl is defective in muscular power, disinclined to take exercise, and prone to distortion of the spine, the sitting position does not afford her rest, in consequence of the great efforts she has to make in order to keep the body erect. A patient in that condition will derive benefit from being obliged to lie for two or three hours daily, at divided intervals, on a sofa or board. When the deformity has actually occurred, gymnastic exercises suggested by the medical attendant will not unfrequently, when continued for some time, have the effect of loosening the connection of the bones, of facilitating their falling into their proper places, when extension is employed, and of restoring to the spine a portion of its lost suppleness. Mr Shaw suggests the following simple plan for attaining the same end. 'Let the patient lie on one side, with a firm cylindrical pillow, six inches in diameter, placed under the gibbosity of that side, and let her rest her weight on the pillow: the effect will be to counteract and reverse the curve. The same may be done alternately on the two sides. The posture may be continued each way for a quarter of an hour at a time, and be repeated twice or thrice daily.'—*Op. cit.*, p. 858. There are two methods of extending the curved spine—viz. (1), by stretching the body while the patient is recumbent; and (2) by letting the patient remain upright, and using spinal supports. As each method has its own advantages, a combination of them will often afford the best results. The chief objections to the former are the necessary confinement, comparative seclusion, and interference with the routine of study. Any mode of treatment with the view of producing extension of the spine must be continued for months in order to be of any avail. It would be altogether out of place to notice in this article the various extending beds, apparatuses for exercise, and different kinds of spinal supports that have been devised by surgeons and anatomical mechanicians, and we will merely observe that mechanical supports must be tried with great caution. They are always more or less irksome to bear, and if they are not doing good, are almost sure to be doing harm. On this subject, the reader may consult Heather Bigg's work entitled *The Spine and Upper Extremities.*

Angular Curvature consists, as already mentioned, of caries of certain vertebræ, which first consumes the bones and fibro-cartilages, and subsequently excites a discharge of pus. The first symptom of this affection is the appearance, at the seat of the caries, of a prominence of one or more of the spinous processes. This 'growing out' of the back, as patients frequently term it, is due to the destruction of a portion of the column. In an advanced stage, the spinal ridge will stand out prominently, the knob of each process being distinctly visible; and finally, a distinct angular projection is developed. The *consequences* of this disease are thus summed up by Druitt. '1. In favourable cases, the diseased bones collapse, and are anchylosed; abscesses, if they form, are healed, or their matter is absorbed, and the patient recovers in two or three years, with more or less deformity, which is, of course, incurable. 2. In some fatal cases, the patient dies suddenly from two or three of the diseased vertebræ giving way, and crushing the spinal cord; or from dislocation of the odontoid process, owing to ulceration of its ligament; or from the bursting of abscesses into the spinal cord; or from their bursting into the pleura or peritoneum; but more frequently death is caused by slow irritation and exhaustion, consequent on the formation of psoas or lumbar abscesses.'—*The Surgeon's Vade-mecum*, 8th ed., p. 348. The most essential point in relation to *treatment* is *rest*, and the most effectual method of arresting motion between the diseased vertebræ, and of keeping them at rest, is by placing the patient in a recumbent position on his back. If possible, an invalid bed should be procured, provided with contrivances for enabling him to lie upon it, day and night, without rising. Local counter-irritants, such as compound tincture of iodine, are often useful; and good diet, backed, if necessary, by cod-liver oil and tonics, must be prescribed. In conclusion, sufferers from any form of real or suspected spinal disease are earnestly warned to avoid the numerous quacks, whether in or out of the medical profession, who have taken up the spine as a specialty.

SPI′NEL, a mineral allied to corundum, consisting chiefly of alumina, with smaller proportions of magnesia, silica, and protoxide of iron. It occurs in crystals, which are often octahedral, and is chiefly found in Ceylon and Siam. Its colours are various; red, blue, green, and black. It is much prized as a gem; red spinels are commonly called rubies; the *Balas Ruby* is a rose-red S., and a violet-coloured S. is known as *Alamandine Ruby.*

SPI′NET (Ital. *spinetta*) an old-fashioned stringed musical instrument with a keyboard, smaller and weaker than the harpsichord, and like it, one of the precursors of the pianoforte. Each note had but one string, which was struck by a quilled jack acted on by one of the finger-keys. The strings were placed horizontally and nearly at right angles to the keys, as in the square pianoforte; and the general outline of the instrument nearly resembled that of a harp laid in a horizontal position, with the keys occupying the position of the sounding-board; on which account the spinet, when first introduced, was called the couched harp.

SPINNING is the art of combining animal and vegetable fibres into continuous threads fit for the processes of weaving, sewing, or rope-making. The most primitive spinning apparatus is the spindle and distaff, representations of which are to be seen on the earliest Egyptian monuments. The distaff was a stick or staff upon which a bundle of the prepared material was loosely bound, and which was held in the left hand or stuck in the belt; the spindle was a smaller tapering piece to which the thread was attached. By a dexterous twirl of the hand the spindle was made to spin round and at the same time recede from the spinster, who drew out between the forefinger and thumb of the right hand a regular stream of fibres so long as the twisting of the spindle lasted. It was then drawn in, the new length of thread wound upon it, and the operation was renewed. An obvious improvement on this was to set

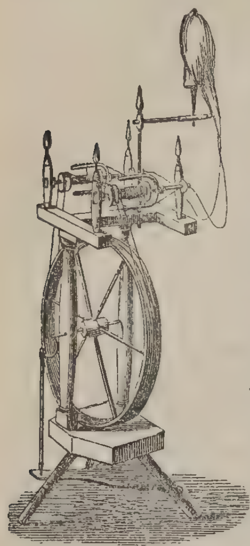

Fig. 1.—Two-handed Spinning-wheel.

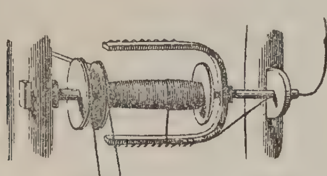

Fig. 2.
Spindle, Bobbin, and Winding-arm on a larger scale.

the spindle in a frame and make it revolve by a band passing over a wheel driven either by occasional impetus from the hand or by a treadle; this constituted the *spinning-wheel*, which is said to have been invented in Nuremberg as recently as 1530. In the spinning-wheel in its most improved form, and as used for flax, a bobbin or 'pirn,' with a separate motion, was placed on the spindle, which had a bent arm—a flyer or flight—for winding the yarn on the bobbin. The spindle and bobbin revolved at different rates, the revolutions of the spindle giving the twist, and the difference of the rate causing the winding on. The two-handed wheel had two spindles and pirns a little apart, with the distaff or 'rock' stuck into the frame between them, and the spinster produced a thread with each hand. The spinning of flax on such wheels for the manufacturer was an important branch of domestic industry in the northern counties of Scotland as late as 1830, if not later.

Neither the spinning-wheel nor the hand could spin more than one, or at most two threads at a time, and therefore with the rapid increase of population, and the improvements made in the process of Weaving (q. v.), they became quite inadequate to supply the demand for yarn: but an accident, it is said, about the year 1764, led to an invention by which eight threads could be spun at once; and this was soon improved upon until eighty could be produced as easily. This was the invention of the *spinning-jenny* for cotton-spinning, by James Hargreaves, at Standhill, near Blackburn in Lancashire. In this machine, a number of large reels of cotton formed into a thickish coil, called a *roving*, were set on upright fixed spindles, and the ends of the rovings were passed between two small movable bars of wood placed horizontally and under the control of the spinner, who could thus make them press more or less on the roving, and consequently increase or decrease the draw upon it from the spinning spindles, which were set in a row at the other end of the frame, and all capable of being set in motion simultaneously by the wheel. The success of the spinning-jenny (fig. 3) was considerable, but its history has been too often told to be required here; and even previous to its invention, a better idea had been started and acted upon by others, and was afterwards brought to such perfection, that the invention of Hargreaves soon passed into obscurity.

In order to understand the operations of spinning as now practised, and as improved by the invention alluded to, it is desirable, in this place, to say a few words upon the preparation of the fibres for the process of spinning. In the first place, if wool or cotton, it has to be 'opened;' that is, it must be relieved from its original knotted and lumpy condition; this was formerly done by hand, but is now easily managed by machines called 'willows or willeys,' 'blowers' and 'openers.' By the first of these, which consists of a drum covered with small spikes moving in a hollow cylinder, also lined with spikes, but so arranged that those on the drum pass close to, but do not come into collision with them as it revolves, the cotton or wool is fed in on one side, is dragged forward by catching on the spikes, and is delivered at an opposite opening to that by which it entered, in a loose state and free from knots. It is not, however, quite loose enough for the subsequent operations, and it is more or less mingled with impurities. It is therefore taken to the 'blower' or 'opener,' and being put into a shaft, is there acted upon by a stream of air violently

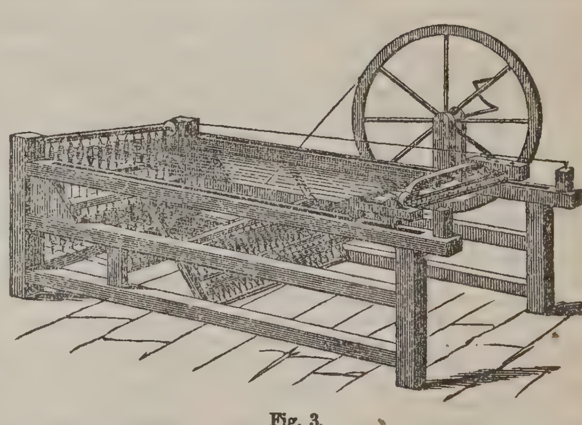

Fig. 3.

driven in by machinery, which blows it forward removes extraneous matters, and so separates the fibres that they pass out at the other end in a

exceedingly light flocculent state, and ready for being formed into *laps*. This operation consists in laying the material very equally on an endless apron made of small bars of wood, and of the width of the frame of the machine in which they are placed. This apron (*a*, fig. 4) passes round two rollers, placed at

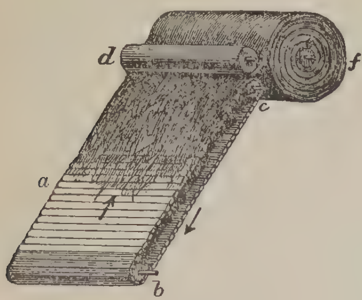

Fig. 4.

a little distance apart, as in fig. 4, *b*, *c*, the rollers being moved by machinery. The arrows indicate the direction in which the apron moves; and as the operator covers its entire surface with a thin layer of the fibre, it passes under the roller *d*, and is taken on to the roller *e*, in the form of a compressed layer of cotton or wool, called a *lap*. When the roller *e* is full, it is removed, with its lap *f*, to make way for another. Much care is taken in weighing out and distributing the material of these laps, because upon this first operation the ultimate size of the yarn depends.

The laps are taken to the *carding-machine*, consisting of a series of cylinders revolving in a frame, and placed so close together that they almost touch each other. Each cylinder is covered with a coating of fine steel wire points, which are stuck in leather, or some other flexible material, and are technically called *cards*. The production of these cards by machinery is in itself a marvel, and the automatic machines for making them are wonderfully effective. Each piece of wire is bent as in fig. 5, and is put through two holes in the leather, as in fig. 6; *a* shews a bent wire going in, and *b*, *b*, wires completely in the holes in leather,

Fig. 5.

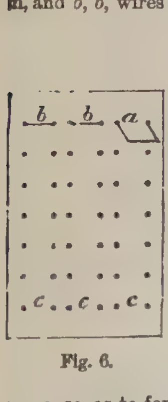

Fig. 6.

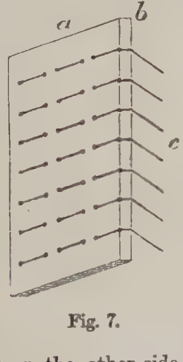

Fig. 7.

c, *c*, *c*, so as to form two points on the other side, and these are slightly bent all in one direction, as in fig. 7, where the piece of card *a* is seen cut through at *b*, to shew the direction given to the wires *c*. There are many variations upon this arrangement of the wires, but the general principle is the same in all. The machine for making the cards cuts the wire to the right lengths, bends them, pierces the holes in the leather, inserts the wires, and finishes by giving them the slight sloping direction which is essential.

The lap is made of the same width as the cylinders of the carding-machine, and is so adjusted that, as it unwinds from its roller, it passes in between a pair of the carding cylinders, the steel wire teeth of which seize hold of the individual fibres, and drag them in one direction until they are caught by other cylinders, and so carried from one to another, always being pulled in a straight direction until they are laid as nearly as possible side by side, and are given off in a thin cobweb-like film at the last cylinder, where it is prevented from continuing its journey round the cylinders by a small bar of metal called the *doffer*, which, with a gentle and peculiar motion, removes it from the cylinder. The film of fibre is of the same width as the cylinder of the carding-machine, but it is gathered together by the operator, who passes it through a smooth metal ring, and between two small polished rollers, the revolutions of which carry it forward, and deposit it in a deep tin can in the form of a loose untwisted column of cotton or wool, about an inch in thickness, which is called a *sliver*. A small portion of this arrangement is shewn in fig. 8, which represents a carding-machine

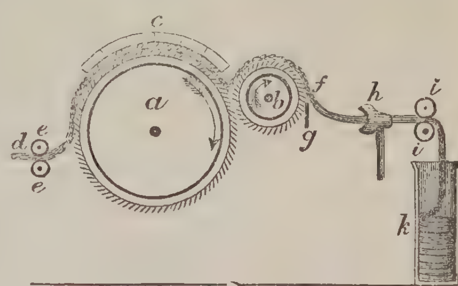

Fig. 8.

with only two carded cylinders, *a* and *b*; they are, however, much more numerous. There is also a concave piece of carding, *c*, which was formerly much used, but has lately given way to additional cylinders, but it makes the action more apparent in a drawing; *d* is the lap drawn on by the action of the two small rollers *e*, *e*, which slightly press it as they revolve. It is quickly distributed all over the surface of the large cylinder *a* by means of its numerous wire-teeth; and as it passes the roller *b*, the teeth of which move in an opposite direction, as indicated by the arrows, the fibres are caught off the large, and are carried round the small cylinder until they reach *f*, where they are stripped off by the doffer *g*, and are passed through the ring *h*, and the rollers *i*, *i*, into the tin receiver *k*. The sliver is now in the first stage of spinning; it has next to be drawn out very gradually until it is not thicker than a quill; and in drawing it out, the operator gives it a very slight twist, still leaving it so loose in structure that it will break with a slight touch; in this state it is called a *roving*; and it was at this stage that the spinning-jenny began to operate upon it. The rovings, which were wound as they were drawn upon large reels, were unwound by the machine, and were still further drawn out and firmly twisted and wound on to spindles or cops, the drawing being regulated by the pressure of the wooden bars of the jenny, which was within reach of the operator's hand.

The *throstle-machine*, patented by Arkwright in

1769, had for its object the drawing of the rovings through a succession of pairs of rollers, each pair in advance of the others, and moving at different rates of speed. The first pair receive the sliver, compress it, and pass it on to the second pair, which revolve at a greater speed, and thus pull it out to exactly the number of times greater length that their revolutions exceed those of the other pair—in number it is usually eight times—and as the first roving is passed through a second, third, and sometimes fourth machine, the finished roving is 32 times longer than the sliver. As the roving issues through the last rollers of each machine, it is received on *spools* or *reels*, calculated to hold a given quantity; and these are transferred to the *spinning-frames*, which resemble the *roving-frames*. Here the roving takes the place of the sliver; and as it unwinds from the spool, is drawn through successive pairs of rollers, moving as before at different rates, each succeeding pair faster than the backward ones, so that the roving gets thinner and thinner, until the tenuity is carried as far as desirable. It is then carried on to a spindle which revolves with great rapidity; and by means of a simple arrangement, is made both to twist the thread and wind it on the spindle ready for the weaver.

This system produces too great a strain upon the thread in its progress to admit of its being drawn so fine as is wanted for many purposes, and this led to the invention of the *mule-jenny* by Crompton (q. v.) in 1779, which has a travelling frame upon which the spindles are set. This frame is now made long enough to carry hundreds of spindles, and it gently draws out and twists the thread after it leaves the last pair of rollers; and when it has reached its limits—now several yards, but in Crompton's time only five feet—it rapidly returns, winding up the spun thread on the spindles as it goes back. These machines are now applied, with various necessary modifications, to cotton, wool, flax, silk, and other textile materials, and the effect they have exerted upon our manufactures is more wonderful than anything in the whole history of commerce. Previous to the invention of the mule, few spinners could make yarn of 200 hanks to the pound (the hank being always 840 yards). At the same time, the natives of India were weaving yarn of numbers ranging between 300 and 400. Now, however, our manufacturers have reached such extraordinary perfection, that Messrs Houldsworth of Manchester have succeeded in making No. 700, which was woven by the French firm Messrs Thivel and Michon of Tavare, and others far too fine to weave, the greatest tenuity reached being 10,000, a pound of which would reach 4770 miles. This was made to test the perfection of the machinery, but was of no practical value.

The most modern improvements in spinning are in the machines of Messrs Platt & Co. of Oldham, which combine all the operations of carding, roving, and spinning in one machine. These and similar machines are now coming into almost universal use for cotton and wool.

SPINOZA, Baruch (= *Benedict*), one of the greatest philosophers of modern times, was born at Amsterdam on the 24th of November 1632. His parents, rich Portuguese Jews, had their son diligently instructed in the Bible and its commentaries, and the Talmud. But after having mastered both, and imbibed the philosophical spirit of such commentators as Aben Ezra, he was allowed —the more readily that his sickly constitution unfitted him for a commercial career—to devote himself entirely to a life of study. Physical sciences and the writings of Descartes, to which he turned first of all, very soon drew him away from the rigid belief and practices of the synagogue; and Saul Levi Morteira, his talmudical teacher, who had built the fondest hopes upon the genius of his pupil, was the first to threaten him with the direst punishment if he did not retract the rank heresies that he began openly to utter. S., after a time, entirely withdrew from the community of his brethren, who formally excommunicated him. A fanatic even attempted to frighten him by an either real or feigned attack upon him as he left the theatre one night. At that period, the young truth-seeker made the acquaintance of the young and beautiful daughter of Van den Ende, his master in Greek and Latin, and fell passionately in love with her, but was rejected. From that time forth, Philosophy became the sole aim and object of his life. In accordance with the teachings of the sages of the Mishna, S. had, apart from his studies, made himself master of a mechanical craft. He had learned the art of polishing lenses. This now became the means of his subsistence. Besides, he was also an expert in the art of design, and among a number of other portraits, he drew one of himself in the dress of Masaniello.

When 28 years old, he left Amsterdam, and went to Rhynsburg, near Leyden, where he wrote the *Abridgment of the Meditations of Descartes*, with an Appendix—the latter being the first cast, so to say, of his *Ethics*. The year following, he removed to Woorburg, near the Hague, and shortly afterwards, yielding to the solicitations of his, by this time, numerous friends, he removed to the Hague itself. The Elector of the Palatinate, Charles Lewis, next offered him a vacant chair at the university of Heidelberg, with full 'liberty of teaching,' provided he would not say aught to prejudice the established religion, i. e., Christianity; whereupon S. declined the both lucrative and honourable professorship. His small pittance was enough to satisfy his wants. In a similar way, he refused generous offers made to him by wealthy friends, like Simon de Vries, who intended to bestow a large sum of money upon him. All he could be prevailed upon to accept was a small annuity of a few hundred florins; the rest he persuaded his generous friend to bestow upon his (De Vries') own brother. An offer of a pension, on the condition of his dedicating a work to Louis XIV., he rejected with scorn. His domestic accounts, found after his death, shew that he preferred to live on a few pence a day, to being indebted to another's bounty. He died, 44 years old, on the 21st of February 1677. Throughout his life of study, of abstemiousness, of bodily and mental suffering—for his constitution was undermined no less by consumption and overwork, than his sensitive mind was wrought upon by the violent severance of all natural ties of affection, to say nothing of the misery of occasional want and of perpetual persecution—no complaint ever passed his lips. Simplicity and heroic forbearance, coupled with an antique stoicism and a childlike, warm, sympathising heart, were the principal attributes of him who was nicknamed epicurean and atheist by his contemporaries. It has well been said, that no man, perhaps, was more filled with religion than S., and that to be an epicure at the rate of twopence-halfpenny a day cannot be a very serious crime.

Respecting S.'s philosophical system, of which we can only give the very faintest of outlines here, it must be premised that it developed itself on the basis of Descartes. The latter had inaugurated a new epoch by his 'reconstruction' of knowledge. Dissatisfied both with the dogma and the scepticism around him, he cleared the ground by first doubting everything, and then laying a new foundation by *Cogito, ergo sum* (I think, I therefore am). S.,

however, deeply struck both with the reasonings and conclusions of Descartes, took his 'I think, therefore I am,' merely as a starting-point to prove more clearly the existence of God than Descartes did. The consciousness of man's own existence and of his imperfect state, are not, he thinks, sufficient to solve the grand problem. He therefore assumes, first of all, three fundamental things, which he calls respectively Substance, Attributes, and Mode. By substance he understands, like Descartes, that which needs nothing else to its existence; but, unlike Descartes, he assumed only One such Substance—God. Yet this term is not to be understood in the ordinary sense, for S.'s God neither thinks nor creates. There is no real difference, he holds, between mind, as represented by God, and matter, as represented by Nature. They are One, and according to the light under which they are viewed, may be called either God or Nature. The visible world is not distinct from him. It is only his visible manifestation, flowing out of him, who is the last fountain of life and essence, as a finite from the infinite, variety from unity—a unity, however, in which all varieties merge again. Extension and thought, which, with Descartes, had been two Substances, with S. become 'Attributes;' that which the mind *perceives* as *constituting* Substance. Extension is visible Thought; Thought is invisible Extension. The relation between Substance and Attributes, S. illustrates by the example of an object—colourless in itself, perhaps—seen through yellow or blue spectacles. And this explains the relation between body and mind, and the complete unity between them. The mind is the idea of the body—i. e., the same thing considered under the attribute of thought. The *modus* or *accidens* is only the varying form of Substance. Like the curling waves of the ocean, they have no independent existence; nay, less than these are they things of reality; but they are simply the ever-varying shapes of the Substance. Substance, thus, is the only really existing, all-embracing essence, to which belongs every thing perceptible to our senses, and not perceptible. Thus, every thought, wish, or feeling is a Mode of God's Attribute of thought; every thing visible is a Mode of God's Attribute of extension. God is the 'immanent idea,' the One and All. 'World' does not exist as world—i. e., as an aggregate of single things—but is one complex whole and one peculiar aspect of God's infinite Attribute of extension. The variety we behold in things is a mere product of our faulty conceptions, particularly of, as S. terms it, our 'imagination,' which perceives unity as a complex of multiplicity.

On these metaphysical speculations he founds his Ethics, which he deduces in a mathematical form, after the method of Euclid. The chief doctrines are: The absence of free-will in man—himself only a *Modus* dependent on causes without, and not within him. Will and Liberty belong only to God, who is not limited by any other Substance. Good and Evil are relative notions, and sin is a mere negative; for nothing can be done against God's will, and there is no idea of Evil in Him. Utility alone, in its highest sense, must determine the good and the evil in our mind. Good, or useful, is that which leads us to greater reality, which preserves and exalts our existence. Our real existence is knowledge. Highest knowledge is the knowledge of God. From this arises the highest delight of the spirit. Happiness is not the reward of virtue, but virtue itself; and this is to be attained by a diligent following in God's ways. Sin, evil, negation, &c., are merely things that retard and obstruct this supreme happiness.

S.'s system, Pantheism or Atheism, as it has been variously called, appears to be nothing but the most rigid, most abstract Monotheism that can be conceived by man. There is only Substance, only God—nought else. It was not unnatural, however, that this system should be misunderstood either as materialism or as pantheism, seeing the word 'substance,' which, with S., means 'existence,' is, in ordinary language, associated with the idea of matter or body. Be this as it may, 'this most iniquitous and blasphemous human invention,' as it has been called for 200 years, has become the acknowledged basis of modern German philosophy; and pious theologians like Schleiermacher did not hesitate to apply the highest terms of 'pious, virtuous, God-intoxicated,' to S., who, we need not add it, never left Judaism, although he left the synagogue and its human formalities.

His principal works are—*Renati Descartes Principiorum Philosophiæ, Pars I. et II., more geometrico demonstratæ* (Amsterdam, 1663); *Tractatus Theologico-politicus* (anonymous, with the feigned place of imprint, 'Hamburg' instead of Amsterdam, 1670; Eng. translation, anonymous, Lond. 1862); the *Opera Posthuma*, edited in the year of S.'s death by Ludwig Meyer and Jarrig Jellas, contain: 'Ethica more Geometrico,' 'Tractatus Politicus,' 'Tractatus de Intellectus Emendatione,' 'Epistolæ,' 'Compendium Grammatices Linguæ Libræææ.' Several other minor treatises are lost. According to Colerus, S. also intended to translate the Bible, and had completed already the Pentateuch, but nothing of it has survived. There is a German translation of S.'s collected works by B. Auerbach (Stuttg. 1841), 5 vols. An English translation, with a Life of S., has been promised by G. H. Lewes.

SPIRÆ'A, a genus of plants of the natural order *Rosaceæ*, and of the suborder *Spiræeæ* in

Queen of the Meadow (*Spiræa Ulmaria*).

which the fruit consists of five or fewer capsular carpels distinct from the calyx, and each containing 1—6 seeds. The genus S. has one or more follicular, many-seeded carpels. It contains a large number

of species, natives of Europe, Asia, and America, herbaceous plants and low deciduous shrubs; of the herbaceous species, two are natives of Britain, DROPWORT (*S. Filipendula*), and MEADOW SWEET or QUEEN OF THE MEADOW (*S. Ulmaria*), both with interruptedly pinnate leaves and flowers in cymes. Dropwort is a native of dry upland pastures; it is tonic and fragrant; and its tubers, which are somewhat nutritious, are in Sweden ground and made into bread. Meadow Sweet is well known for the powerful fragrance of its flowers. A fragrant distilled water is prepared from them. A North American species (*S. tomentosa*), called HARDHACK in the United States, is there used as a tonic and astringent. Many of the shrubby species are frequently planted for ornament.

SPI'RAL, in Geometry, is the name given to a class of curves which, during their gradual regression from a point, wind round it repeatedly. Their equations are generally expressed in terms of polar co-ordinates, and are all necessarily of the form $r = f(\theta)$, where θ never signifies a function of the angle, but the angle itself or a multiple of it. Several such curves have received distinguishing epithets, either on account of the properties they possess, or from their inventors; the chief of them are—the *equable spiral* or the *spiral of Archimedes*, whose equation is $r = a\theta$, and which, commencing at the origin, circles round and regredes from it with unvarying uniformity; the *hyperbolic* or *reciprocal spiral* ($r\theta = a$); the *logarithmic* or *equiangular spiral* ($r = ab^{\theta}$); which recedes from the centre or origin with a velocity increasing as the distance, and always cuts the radius vector at the same angle; &c.

SPIRAL VESSELS are those very delicate air-tubes in the cellular tissue of plants which run unbranched through the different parts of the plant, and whose walls are composed of fibres spirally or circularly twined. Spiral vessels are either *free*, when their windings are unconnected with each other, or *net-like*, when the windings are involved with each other in a net-like manner. If the free spaces between the convolutions in the latter are linear, they form *lined* vessels; but if they are point-like, they form *punctate* or *porose* vessels. Spiral vessels, whose walls are formed of distinct horizontal rings, placed simply one above another, are called *annular* vessels. Spiral vessels seldom occur singly, but are generally united by cells into bundles called vascular bundles. These vascular bundles are scattered in the stems of endogenous plants; but in the stems of exogenous plants they are arranged in one or more concentric circles. Amongst cryptogamous plants, the ferns alone (in the most extensive signification of the term) are provided with spiral vessels. All plants which have spiral vessels are called *Vascular Plants*, in contradistinction to *Cellular Plants*, whose substance consists of cells only.

Through the operation of what laws the spiral form is assumed by spiral vessels, is still unknown, although the question has naturally been regarded as having an intimate connection with the tendency to spiral structure manifested in plants, and even in some of those cryptogamous plants in which no true spiral vessels are found; a tendency which is observed not only in spiral stems, spiral tendrils, the spiral fibres of the elaters of *Jungermanniæ*, and the like, but throughout the vegetable kingdom generally in the spiral arrangement of leaves and of the organs which are formed by the metamorphosis of leaves. The whole subject is an extremely difficult one; there has been much speculation about it, but as yet with no satisfactory results.

SPIRE, a very acute pyramidal roof in common use over the towers of churches. The history of spires is somewhat obscure, but there is no doubt that the earliest examples of anything of the kind are the pyramidal roofs of the turrets of Norman date. Those of St Peter's, Oxford (fig. 1), and Rochester Cathedral (fig. 2), are good specimens of circular and octagonal spires on a small scale. Spires of this early period are much lower than those of later date. The early English style has spires of acute form over the larger towers. They are generally what are termed broach spires, i. e., the slopes spring from the cornice of the tower without any parapet, and at the point where the square changes to the octagon, there is a small set-off or separate roof. (Fig. 3, St Mary's, Cheltenham, indicates this arrangement.) Sometimes the angles at top of towers were occupied with pinnacles or sloping

1, Turret, St Peter's Church, Oxford; 2, Turret, Rochester Cathedral; 3, St Mary's Church, Cheltenham; 4, Bayeux Church, Normandy.

(From Parker's *Glossary of Architecture.*)

masses of masonry, as at Bayeux Cathedral, Normandy (fig. 4).

In the Decorated style, the spires were more enriched, with a parapet and pinnacles at the top of the tower, crochets on the angles, and enriched windows.

The spires of the Perpendicular and Flamboyant styles are still more enriched, with flying buttresses at the angles, &c. They are sometimes perforated, and the sides of the spire filled entirely with tracery. Such spires are common in Germany, those of Strasbourg and Freiburg on the Rhine being very fine examples. As in the later styles generally, the character and beauty of the spire give place to dexterity in masonry, and many examples exist of traceried spires more wonderful than beautiful. See GOTHIC ARCHITECTURE.

Spires are most frequently constructed of stone, but they are also occasionally made of wood, and covered with lead, copper, slates, or shingles. These are chiefly to be found in localities where stone is scarce.

SPI'RIFER, a genus of fossil brachiopodous mollusca, containing upwards of 200 described species, which have been found in all the strata from the Trias to the Silurian inclusive. They belong to a small group characterised by the possession of two calcareous spiral processes which support the oral arms. The shell and spines are occasionally found silicified in the limestone rocks, and they may then be beautifully developed by means

of acid. They are used with other similar fossils by the Chinese in medicine.

SPIRIT, a name of very general application to fluids, mostly of a lighter specific character than water, and obtained by distillation. Thus, the essential oil of turpentine is called Spirit of Turpentine. Essential oils dissolved in alcohol are called spirits, as Spirit of Aniseed, Peppermint, &c., because formerly prepared by distilling the herbs with alcohol. The volatile alkali ammonia, distilled and condensed in cold alcohol, is called Spirit of Ammonia; even hydrochloric acid is often called Spirit of Salts. But in a stricter sense, the term spirit is understood to mean Alcohol (q. v.) in its potable condition, of which there are very numerous varieties, deriving their special characters from the substances used in their production. Besides the more common kinds, such as Brandy, Rum, Whisky, Gin, Arrack, &c. (see those heads), there are others less well known. In Italy, potable spirits are distilled from the fruit of the Arbutus (*A. Unedo*), from the bulbs of the Asphodel (*A. racemosus*), and the Sea-daffodil (*Pancratium maritimum*). In tropical countries, of late, spirits have been distilled from a great variety of fruits, as the Caju or Cashew, the Indian Fig (*Opuntia*), the Mammee, Oranges, &c.; and in the West Indian Islands, large quantities of a spirit used in medicine, perfumery, and for toilet purposes, are made from the berries of *Myrtus acris* and *M. pimentoides*, under the name of Bay-rum. In the north of Europe, potato spirit is largely made and consumed; and much spirit is now made on the continent from beet-root. In the United States the sale of whisky during the year ending June 30, 1871, was estimated at 60,000,000 galls.; of imported spirits, 2,500,000 galls.; imported wine, 10,700,000 galls.; ale, beer, and porter, 65,000,000 bbls.; native brandies, wines, &c., estimated to be worth $31,500,000; a total valuation of $600,000,000. Prof. Leone Levi estimated in 1870 that 846,000 persons, or, including dependents, 1,500,000, are employed in the liquor trade in Great Britain. The production of beer requires a fixed capital of $220,000,000, and the floating capital employed in making beer, spirits, and importing foreign wines and spirits is $392,000,000.

SPIRIT DUCK. See GARROT.

SPI'RITO SA'NTO. See ESPIRITU SANTO.

SPI'RITUALISM, a system of professed communication with the unseen world, which originated in America about the year 1848, rapidly developed itself in that country, and extended to other parts of the world, obtaining many adherents in Europe, particularly in England and France. In 1859, the Spiritualists reckoned 1,500,000 avowed adherents of their system in America, 1000 public advocates of it, and 30 periodicals devoted to its cause, besides hundreds of books and pamphlets that had already issued from the press. Since that time, the fervour of public excitement on the subject has somewhat diminished, but not the confidence of many believers in Spiritualism, nor their zeal in its advocacy; whilst many additions have been made to its literature, in Britain as well as in America. Amongst its adherents are many persons, particularly in the United States, of high social position and good education, and even some of superior literary and scientific attainments.

Attempts have been made to trace the origin of Spiritualism to the writings of Swedenborg, and there is reason to think that the activity of some of his followers in America contributed to prepare the public mind in some measure for pretensions somewhat similar to his own; an effect which some strange manifestations among the Shakers in the state of New York, in 1843, attracting much attention, probably also concurred in producing. The Spiritualists find their own appearance at the present day predicted in the writings of Swedenborg, but the Swedenborgians hold themselves aloof from them, because they do not follow Swedenborg with implicit reverence; their belief in intercourse with spiritual beings is essentially the same, only differently developed, and in a very different relation to Christianity.

Spiritualism has also in its origin an intimate connection with Animal Magnetism and Clairvoyance. In the article ANIMAL MAGNETISM, it has already been attempted to shew how many of the phenomena of Spiritualism may be rationally explained, without the supposition of imposture, and to this we shall not further refer. Of course, the possibility of such an explanation of phenomena which have astonished many previously most incredulous, and made them at once extreme in their credulity, is not incompatible with the belief, that there has been much imposture practised by those who have made Spiritualism a trade and means of gain.

Spiritualism, strictly so called, may be said to have had a precursor in Andrew Jackson Davis, known in America as 'the Seer of Poughkeepsie.' Davis was born in 1826, of humble parentage, his father being a cobbler, in Orange County, state of New York; spent his youth in tending cattle, was at school only for five months, and was there regarded as a dunce. He seems, however, to have been a dreamy youth; he saw visions, and he heard voices, which sometimes distinctly said: 'To Poughkeepsie;' and thither he induced his parents to go, the village cobbler becoming a journeyman shoemaker, and his son an apprentice to the same trade. Wonderful communications from the unseen world continued to come to him, which he believed to be from the disembodied spirits of human beings. When he sung songs, he often imagined that spirits replied to him, sometimes contradicting what the song expressed; particularly when he sung a temperance song which speaks of our friends once dear as 'in their graves laid low,' to which a voice always answered 'No.' In the end of 1843, after the visit of an itinerant mesmerist to Poughkeepsie, a tailor, named Levingston, discovered Davis to possess astonishing powers of clairvoyance, and particularly of revealing the 'interior condition' of his visitors, so that he could tell their diseases and prescribe for them. These powers Mr Levingston suggested that he should employ for the good of his fellow-creatures; and he began, with Levingston as his companion and guardian, a round of visits to the towns of the United States, looking through the bodies of invalids, revealing their complaints, and prescribing for them, for the fee of five dollars. His success was very great, in the city of New York and elsewhere. At Bridgeport, in Connecticut, he found two gentlemen, Dr Silas Smith Lyon and Mr William Fishbough, who appreciated his powers very highly, persuaded him to throw up his connection with Levingston, and under their guidance, to enter on a still more adventurous and lucrative career, in making revelations concerning the unseen world. Levingston afterwards disputed these revelations, and ascribed them to Lyon and Fishbough as their authors; but they were readily received by many in all parts of America, notwithstanding their very extraordinary character. Davis, it was now alleged, entered for the first time permanently on what he calls *clairscience*, or *the superior condition*, far above that of ordinary clairvoyance; and proceeded to dictate a book, of the *Principles of Nature*, or 'divine revelations of Nature,' which in due

time was followed by *The Great Harmonia; being a Philosophical Revelation of the Natural, Spiritual, and Celestial Universe.* It is impossible to exhibit in our space more than a specimen or two of the strange things which these books contain. Nor can we afford to quote from the grotesque verse of the *Divine Harmonia.* A new view of the spiritual world was presented to mankind. Sin was declared not to exist; and the interior principle of man to be of divine origin, and incapable of contamination, all evil being merely external. With these views were associated such as the following sentences express: 'It is a law of matter to produce its ultimate, mind.' 'All ultimates are matter.' 'Man, spiritually, is the perfection of motion.' 'The universe is animated by a living spirit, to form the whole, *one grand man.*' 'Man is a part of this great body of the Divine Mind. He is a gland, a minute organ.'

Davis represented himself as obtaining knowledge of any kind and on any subject, according to his wish, in his *superior condition.* 'I pass from the body,' he says, 'with a desire for a particular kind of information. This desire attracts the particular kind of truth of which I would be informed, separates it from all other things, and causes it to flow into the mind.' Thus he was easily able to exhibit a complete scheme and history of the universe, going back to the beginning, when 'the *Univercœlum* was one boundless, indefinable, and unimaginable ocean of liquid fire.' The universe is declared to consist of seven concentric spheres, surrounding the centre of the earth, and at distances increasing outwards, each of which 'is but one beautiful step in the ladder that reaches to heaven, and the seventh is the most beautiful of all.' Davis does not hesitate to describe the inhabitants of the various planets, and very extraordinary beings they are—those of Saturn, for example, being morally and intellectually perfect; those of Jupiter, in size, beauty, and symmetry of form, excelling the earth's inhabitants, but walking like quadrupeds; those of Mars having hair, not on their heads, but on the back of their necks; &c. It was left for others after him, however, to improve the scheme of Spiritualism, by peopling the different spheres with the disembodied spirits of men who once inhabited the earth, particularly to declare the conditions of their existence in one sphere and another, and readily to summon them from any of the spheres to hold communication with their friends or with curious inquirers in this world.

Whilst the public mind in America was much occupied with the revelations of Davis, new wonders claimed attention. In April 1848, strange rappings began to be heard in a house in the town of Acadia, state of New York, inhabited by Mr Fox. A young girl, a daughter of Mr Fox, imitated the rappings by snapping her fingers, and to the surprise of the family, there was an evident response. The question was then asked: 'Are you a human being?' and there was no reply; but to the question: 'Are you a spirit?' a reply was made by two distinct knocks. Means were thus found of opening up communications; and by rapping in reply to questions, and in assent to letters of the alphabet, so as to spell out words, the mysterious visitor declared himself to be the spirit of a man who had been murdered in that house some years before. Further progress in the art of communication with the unseen world was soon made; it was found that disembodied spirits were quite ready to come when required, and answer by rapping such questions as might be proposed to them, although only certain persons, supposed to be constituted somewhat differently from others, were capable of becoming *mediums* of communication with them. Misses Catherine and Margaretta Fox were excellent mediums, and they were gradually induced, by the pressure of public curiosity, and a desire of vindicating themselves from the charge of imposture, to exhibit their gifts in various towns of the United States. Many others soon followed their example, and the belief in Spiritualism spread very rapidly and widely, amidst much newspaper discussion and other controversy.

Nor did the spirits long continue to make known their presence or make communications to mortals by rapping alone. Mediums became celebrated for tipping or turning of tables under a slight contact of the finger, for moving heavy bodies without contact, for producing phosphorescent lights in a dark room, for playing on musical instruments, for writing, drawing, &c. Particular use was made of a simple method of obtaining communications from spirits by means of 'the card-process,' the letters of the alphabet being printed on a card, and the medium, under spirit-guidance, spelling out the requisite words. Writing mediums, regarded as the mere instruments of the spirits, made the intercourse still more easy and rapid. All this, and much more, was received and implicitly credited by multitudes; while vast numbers, after witnessing the alleged phenomena, continued to believe that there was nothing in them but imposture on the one hand and delusion on the other.

Spiritualism could not long be confined to the land of its birth. From time to time, after 1852, American mediums of note, of both sexes, took up their abode in London, where they exhibited the various phenomena, generally receiving a small fee from their visitors. As in America, private circles were gradually formed, in order to test the truth of the alleged facts, free from the suspicion naturally arising in connection with paid mediums. And it was matter of general surprise how wide-spread, for a short time, became the furor for table-turning, table-tipping, and other modes of inducing the supposed action of disembodied spirits. These practices were not confined to a low and under-educated grade of society; they were in vogue chiefly among the upper classes, although little countenanced by men of science. Mr Faraday announced, that when a sheet of paper was placed on the table, the table did not turn under the finger, whence he inferred that, unconsciously, rotatory impulse was given by the votaries; but the believers were little affected by this objection, asserting that the necessary conditions were in that case simply marred; while the test altogether failed to apply where tables moved without contact, and in many others of the phenomena. Before 1858, there were several native mediums in London, mostly amateur, and only practising in privacy, and there was no lack of controversy on the subject; but faith in the phenomena did not spread with more than a small share of the facility which had been experienced in America. A considerable impulse was given to it by the arrival of a medium from that country (1855) whose qualifications seemed to be super-eminent. This was Mr Daniel D. Home, a young man of humble birth and narrow education, who states that from his cradle mystic circumstances had taken place in connection with his person, and who had actually been turned out of doors by an aunt, his early protectress, in consequence of the diabolic disturbance, as she considered it, which he was the means of creating. In the presence of Mr Home, an accordion held by the end opposite to the keys played the finest music; tables and chairs moved without contact; the hands of disembodied

spirits appeared at the side of a table, or touched the knees of those sitting at it; mystic lights were seen. Most surprising of all, it was stated by various professed eye-witnesses that Mr Home was occasionally lifted off his feet and passed floating through the air, while the accordion would also float about under the ceiling of the room, discoursing the divinest voluntaries. Mr Home is understood to have been received in the privacy of many of the sovereigns of Europe, particularly the Emperor Napoleon, who, when asked if he believed these strange things to be true, answered: 'I *know* them to be so.'

The chief obstacle, in most minds, to a belief in Spiritualism is the obvious consideration, that, while the conjuror can cheat the ordinary observer so wonderfully, the medium may do so too. And this view is supported by one or two circumstances calculated to excite suspicion, viz., that generally the spirits will only work in the dark, and that the presence of a determined sceptic is unfavourable to their manifestations. Nevertheless, Spiritualism has impressed itself as a truth in quarters where its reception was least to be expected; and many excellent persons declare that they have found a comfort in its teachings which they have been able to obtain from no other source.

The reader who wishes to learn more of Spiritualism, has a wide range of books of information open to him. For an account of the early proceedings of the Fox family and others in America he is recommended to consult Capron's *Modern Spiritualism, its Facts and Fanaticisms* (Boston, U. S., 1855). For a view of the higher phenomena since brought into notice, *Incidents in my Life*, by D. D. Home (Lond. 1863), may be recommended. In *Spirit Drawings, a Personal Narrative*, by W. M. Wilkinson (Lond. 1858), will be found a curious history, relating how the author's wife, ignorant of art, was impelled to produce a series of elaborate drawings of the greatest beauty, and all having a mystic significance. There is, however, no English publication which gives a more interesting view of these alleged wonders than a volume entitled *From Matter to Spirit* (Lond. 1863), which is understood to detail ten years' experiences in spirit manifestations of the wife of a distinguished mathematician, a professor in London University College, who prefixes a preface full of curious reasonings on the subject.

A brochure privately printed (1865) under the title of *Remarks on Certain Phenomena*, endeavours to meet the great objection of the scientific world to Spiritualism, viz., that it exhibits a system of supernaturalism, by asserting on the contrary that, though but imperfectly understood, it appears, from its connection with physical and physiological conditions, to be as purely a part of nature as the phenomena of the living organism. According to this writer, the Emperor Julian was a medium affected by communications from pagan spirits, and the religion founded by Mohammed had spiritual communications for its basis. The late Professor Baden Powell, in his Essay on the Spirit of the Inductive Philosophy, seems to intimate an inclination to believe that spiritual phenomena will yet be recognised as a part of the domain of nature, and become a subject for philosophic investigation. In the present state of science, he remarks, 'of all subjects that on which we know least is perhaps the connection of our bodily and mental nature, the action of the one on the other, and all the vast range of sensations, sympathies, and influences, in which those affections are displayed, and of which we have sometimes such extraordinary manifestations in peculiar states of excited cerebral or nervous action, somnambulism, spectral impressions, the phenomena of suspended animation, double consciousness, and the like. In such cases, science has not yet advanced to any generalisations; results only are presented which have not as yet been traced to laws; yet no inductive inquirer for a moment doubts that these classes of phenomena are all really connected by some great principle of order. If, then, *some peculiar manifestations* should appear of a more extraordinary character, still less apparently reducible to any known principles, it could not be doubted by any philosophic mind that they were in reality harmonious and conspiring parts of some higher series of causes as yet undiscovered. The most formidable outstanding apparent anomalies will at some future time undoubtedly be found to merge in great and harmonious laws, the connection will be fully made out, and the claims of order, continuity, and analogy, eventually vindicated.'

SPIRO'PTERA (Gr. *speira*, a coil, and *pteron*, a feather or wing) is the name which has been given to a supposed genus of parasitic worms. Only one species, *S. hominis*, has been described. There is only one case on record of these worms being found; and it was, however, distinctly shewn in 1862 by Schneider, who had carefully examined the specimens in the Berlin Museum, which had been sent thither half a century previously, that the so-called *Spiroptera hominis* is neither more nor less than the exceedingly common nematode worm which abounds in the cod and haddock, and is known as the *Filaria piscium*.

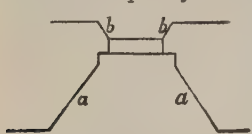
SPI'RULA, a genus of dibranchiate Cephalopoda (q. v.), constituting the family *Spirulidæ*. The animal resembles a cuttle-fish, having, like it, eight arms, two tentacles, and an ink-bag; but it is destitute of fins, and has a chambered shell, like that of the nautilus. Three species have been distinguished, all inhabiting the seas of the warmer parts of the world, particularly of the southern hemisphere. Shells of Spirulæ are strewed in abundance on the shores of New Zealand. A few are brought by the Gulf Stream to the south coast of Ireland and the south-west coast of England. The Spirulæ are extremely interesting, from their relation to ammonites and other fossil cephalopods.

SPI'TALFIELDS, a district of London, adjoining Bethnal Green, derives its name from the *hospital* of St Mary, founded there, in 1197, by Walter Brune and his wife Rosia, and is inhabited chiefly by silk-weavers and other poor people. The manufacture of silk was established in S. by emigrants from France, after the revocation of the Edict of Nantes.

SPI'THEAD, a celebrated roadstead on the south coast of England, and a favourite rendezvous of the British navy, is the eastern division—the Solent (q. v.) being the western division—of that strait which separates the Isle of Wight from the mainland. It is protected from all winds, except those from the south-east, and its noted security warranted the name, which has been applied to it by sailors, of the 'king's bedchamber.' It receives its name from the 'Spit,' a sandbank stretching south from the English shore for three miles; and it is 14 miles long by about 4 miles in average breadth. Here, in 1797, the sailors of the Channel Fleet mutinied for more liberal pay and allowances, which were granted to them. See SPITHEAD FORTS in SUPP. in Vol. X.

SPITZBE'RGEN, a group of islands in the Arctic Ocean, in lat. 76° 30′—80° 40′ N., and long. 9°—22° E., lies 300 miles north of Scandinavia, and 325 east of Greenland. The group, which is estimated to contain about 30,000 Eng. sq. m., is composed of three large and several small islands. The largest of the group, *Spitzbergen Proper*, consists of two oblong and parallel tracts known as West S.

and East S. or New Friesland, connected by a neck of land; the whole strongly resembling a boat-hook in shape. The two next in size are *Egede* and *North-east Island*. Being far within the Arctic Circle, and surrounded by a wide expanse of sea, almost the whole of its surface is covered with perpetual snow and glaciers. The whole of the west side is mountainous, the general elevation being 3000—4500 feet above sea-level; and the same is true of the north-east coast. During ten months of the year, mercury freezes, and for the other two months, the temperature is seldom more than 5° above the freezing-point; yet, during this short summer, about 40 species of plants, which constitute the scanty vegetation of this inhospitable region, succeed in springing up, and producing and ripening their seed. The whole of S. could not afford sustenance for one human being; but it is, nevertheless, a haunt of reindeer, foxes, and bears, and whales and seals abound on the coasts. S. has from time to time been occupied by Dutch and Russian colonies, who were supplied from the mainland of Europe. It was discovered, in 1596, by William Barentz, the Dutch explorer, in his third voyage to discover the North-east Passage, and has since been frequently visited by other explorers and by whalers. It is claimed as a dependency of its European territories by Russia.



Splay.

SPLAY, the sloping or bevelled opening in window recesses and such openings, as at *a*, *a*. Also the corner taken off the outer angle of such openings, as at *b*, *b*.

SPLEEN, The, is the largest and most important of the so-called ductless glands, whose chief object is supposed to be to restore to the circulation any substances that may have been withdrawn from it. It is of an oblong flattened form, soft, of very brittle consistence, highly vascular, of a dark bluish-red colour, and situated on the left hypochondriac region, with its interior slightly concave surface embracing the cardiac end of the stomach and the tail of the pancreas. (See the figure in the article PANCREAS.) It is invested by an external or serous coat, derived from the peritoneum, and an internal fibrous elastic coat. Mr Gray, who wrote the Astley-Cooper Prize Essay, *On the Structure and Use of the Spleen*, states that the size and weight of this organ are liable to very extreme variations at different periods of life, in different individuals, and in the same individual under different conditions. In the *adult*, in whom it attains its greatest size, it is usually about five inches in length, three or four in breadth, and an inch or an inch and a half in thickness, and weighs about seven ounces. At *birth*, its weight in proportion to that of the entire body is as 1 to 350, which is nearly the same ratio as in the adult; while in *old age* the organ decreases in weight, the ratio being as 1 to 700. The size of the spleen is increased during and after digestion, and is large in highly fed, and small in starved animals. In intermittent fevers and leucocythemia, it is much enlarged, weighing occasionally from 18 to 20 lbs., and constituting what is popularly known as the *ague-cake*.

On cutting into the spleen, a section of it shews the presence of numerous small fibrous bands termed *trabeculæ*, united at numerous points with one another, and running in all directions. The parenchyma, or proper substance of the spleen, occupies the interspaces of the above described areolar framework, and is a soft pulpy mass of a dark reddish-brown colour, consisting of colourless and coloured elements. The *colourless elements* are described by Gray as consisting of granular matter, of nuclei about the size of the red blood-discs, and a few nucleated vesicles; and as constituting one-half or two-thirds of the whole substance of the pulp in well-nourished animals, while they diminish in number, and sometimes altogether disappear in starved animals. The *coloured elements* consist of red blood-discs and of coloured corpuscles either free or included in cells; sometimes enlarged blood-discs are seen included in a cell, but more frequently the enclosed discs are altered in form and colour, as if undergoing retrograde metamorphoses. Besides these, numerous deep-red, or reddish-yellow, or black corpuscles and crystals, closely allied to the hæmatin of the blood, are seen diffused through the pulp-substance.

The venous blood of the spleen is carried away by the splenic vein, which contributes to form the great portal venous system, distributed through the liver; while arterial blood is supplied by the splenic artery, the largest branch of the cœliac axis. The branches of this artery subdivide and ramify like the branches of a tree, with the *Malpighian* or *splenic corpuscles* attached to them like fruit. These splenic corpuscles, originally discovered by Malpighi, are whitish spherical bodies, which are either connected with the smaller arterial branches by short pedicles, or are sessile upon their sheaths. They vary considerably in size and number, their diameter usually ranging from one-third to one-sixth of a line. Each consists of a membranous capsule, homogeneous in structure, and formed by a prolongation from the sheath of the artery. The blood-vessels ramifying on the surface of a corpuscle consist of the larger branches of the artery with which it is connected, of venous branches, and of a delicate capillary plexus. From this arrangement of the vessels, it may be inferred that active changes are carried on in the contents of these corpuscles, which consist of a soft, white, semi-fluid substance, made up of granular matter, nuclei similar to those found in the pulp, and a few nucleated cells. These splenic corpuscles are much more distinct in early life than subsequently, and are much smaller in man than in most mammals. They, however, bear a remarkable relation to the general state of nutrition, being much the greatest in well-fed animals, especially in the early periods of the digestion of albuminous food; while they diminish extremely in ill-fed animals, and in those that have been starved, they disappear altogether.

The chemical composition of the spleen confirms the view that a retrograde change of tissue occurs very freely in it. In 1000 parts, there were found (by Oidtmann) nearly 250 of solid residue, of which more than 243 was organic, consisting of albumen, fats, inosite, uric acid, sarcine, xanthine, leucine, tyrosine, and pigment, all of which, excepting the first two, are products of the metamorphosis of tissue. This gland also contains a large quantity of oxide of iron, obtained probably from the disintegration of red blood-discs in it.

With regard to its uses, it may be regarded as a storehouse of nutritive material, which may be drawn upon according to the requirements of the system; and of the exertion of an assimilative action upon the albuminous matter, during its withdrawal from the general current of the circulation, we have direct evidence in the large increase in the proportion of fibrin contained in its venous blood—the blood of the splenic vein sometimes containing nearly six times the usual quantity of fibrin. Before the institution of the chemical inquiries which led to the above conclusion, it was held that the function of the organ was to act as a reservoir for the portal

blood, with the view of preventing the portal vessels from being unduly distended during the digestive process. To what extent it is the seat of the disintegration of old blood-corpuscles, and of the formation of new ones, is still uncertain. The removal of this organ from the body has frequently been performed in animals without serious effects; but in some of these cases, small secondary spleens are developed, and in others, various sets of lymphatic glands are observed to increase rapidly, shortly after the operation, and these probably act vicariously for the spleen. Its singular and complicated microscopic structure, and its extreme vascularity, would lead to the inference that this is a highly important viscus.

It is unnecessary to enter into any detail regarding the diseases of the spleen, as most of them occur secondarily in the course of other affections, as in Intermittent Fever (Ague) and Leucocythemia (q. v.), when it is sometimes enlarged to 40 times its natural weight. It is sometimes diminished to the size of a walnut, the cause of this atrophy being unknown, but the apparent result being a loss of colour, and a comparatively bloodless condition. The spleen is also liable to the singular morbid change known as *Waxy Degeneration* in which the presence of starch-like amyloid granules is observed in the tissue on submitting it to a microscopico-chemical investigation. These remarkable granules dissolve when heated in water, and by the action of iodine acquire a bluish tint, but not the pure iodide of starch purple. In their ultimate composition, however, these granules resemble the albuminates rather than starch, inasmuch as they contain nitrogen.

SPLEE′NWORT. See ASPLENIUM.

SPLE′NIC APOPLEXY, a disease of cattle and sheep, resembles Black Quarter (q. v.) in suddenly attacking animals in good thriving condition, and, like it, appears to depend upon the rapid manufacture of insufficiently elaborated blood, probably faulty in the healthy proportion of some of its constituents. The animal staggers, froths at mouth, throws itself about in convulsions, and sometimes dies within an hour. Few cases recover. The blood is thin, dark-coloured, and indisposed to coagulate. It accumulates in the large internal organs, particularly in the liver and spleen, and is poured out on the mucous surfaces. If the animal is seen in time, and before the pulse becomes small and weak, a moderate bleeding may be tried. A full dose of physic, with a prompt stimulant, must at once be given, and cloths wrung out of hot water applied, for several hours continuously, to the belly and loins. If the animal is weak, and the pulse scarcely perceptible, stimulants must be freely given from the first; and where there is stupor, cold water likewise applied to the head. To prevent the disease, attention must be paid to regular moderate feeding; abundance of wholesome water must be supplied; the grazings not allowed to become too rank, and changed occasionally; rock-salt placed within reach; and a seton inserted in the dewlap of all cattle and sheep pastured upon lands subject to splenic apoplexy.

SPLENISA′TION is a term employed in Morbid Anatomy to indicate a diseased condition of the lung, in which the tissue of that organ resembles that of the spleen in various physical points, such as softness, friability, &c.

SPLINT, or SPLENT, is a bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or both fore-legs, frequently situated between the large and small canon bones, depending upon concussion, and most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender, and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be applied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture every hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool, and free from tenderness, the swelling, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly-blister, or the firing-iron.

SPLINT-BONES. The horse and certain allied mammals have what is popularly known as an outer and an inner splint-bone in the skeleton of the leg. Beyond the bones of the carpus and tarsus, there is one very large bone (the metacarpal or metatarsal of the third toe), which supports the whole weight of the animal. On either side of this bone are the outer and inner splint-bones, which are small bones, not running more than half the length of the great central bone, into which they merge. They represent, in a rudimentary form, the metacarpal and metatarsal bones of the fourth and second toe.

SPLINTS, in Surgery, are certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the fractured ends; they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, &c.

Ordinary splints are composed of wood carved to the shape of the limb, and padded; the best pads being made out of old blankets, which should be cut into strips long and wide enough to line the splints, and laid in sufficient number upon one another to give the requisite softness. The splints should be firmly bound to the previously bandaged limb with pieces of bandage, or with straps and buckles; care being taken that they are put on sufficiently tight to keep the parts immovable, and to prevent muscular spasm, but not so tight as to induce discomfort. Gutta percha, sole-leather, or pasteboard, after having been softened in boiling water, may in some cases advantageously take the place of wooden splints. They must be applied when soft to the part they are intended to support, so as to take a perfect mould, and then be dried, stiffened, and, if necessary, lined. An account of the more complicated kinds of splint required in certain cases, as Macintyre's Splint, Liston's Splint, &c., may be seen in any illustrated catalogue of surgical instruments.

The ordinary splint is now to a great degree superseded by immovable bandages, which consist of the ordinary bandage saturated with a thick mucilage of starch, or with a strong solution of a mixture of powdered gum-arabic and precipitated chalk, which, when dry, form a remarkably light but firm support. As, however, these bandages require some hours to dry and become rigid, means must be used to counteract any displacement of the limb in the interval. On this account, many surgeons prefer the plaster of Paris or gypsum bandage, which is applied in the following manner: the limb being protected by a layer of cotton-wool, a bandage composed of coarse and open material, into which as much dry powdered gypsum as possible has been rubbed, must be immersed in water for about a minute, and then rolled around the limb in

in spiral manner, just as an ordinary bandage; after every second or third turn of the bandage, the left hand of the surgeon should be plunged into water, and smeared over the part last applied. When the whole has been thus treated, the exterior of the bandage should be smeared over with a paste of gypsum and water until a smooth surface and complete rigidity have been attained—a process not occupying more than ten minutes or a quarter of an hour. In a case of simple fracture, where no surgical aid is at hand, any non-professional person of ordinary intelligence might apply this bandage, extreme care being taken that the ends of the broken bone are in their proper position.

SPLÜ'GEN, a mountain of the Lepontine Alps, in the Grisons, Switzerland, whose summit, 9600 feet high, bears the name of the Tombenhorn. The pass of the Splügen, connecting the south-east of Switzerland with the region of Italy round Lake Como, is at its highest point 6940 feet above the sea, and in its present condition is the work of the Austrian government (1823). The southern or Italian descent has three great 'galleries'—i. e., covered portions of the pass constructed of solid masonry, and intended to protect the road from avalanches. They are the longest on any Alpine high-road. When Marshal Macdonald conducted the French army of reserve across the S. by the old path, 27th November—4th December 1800, he lost severely in men and horses from the fall of avalanches.

SPOHR, LUDWIG, an eminent German musical composer and violinist, son of a physician of Brunswick, and born in that town in 1784. He began his violin studies in boyhood; at the age of twelve, he played a violin concerto of his own at the court of Brunswick; and at thirteen he obtained an appointment as chamber-musician to the duke. A few years later, he made a musical tour through Russia and Germany, giving concerts, and acquiring a high reputation as a performer on the violin. In 1804, he became music director at the court of Saxe-Gotha, and held afterwards for several years the office of Music Director of the Theater an der Wien at Vienna. He visited Italy in 1817, Paris in 1819, and in 1820 appeared in London, where he was received with great applause at the Philharmonic Society's concerts, and produced two symphonies and an overture. In 1823, he became Kapellmeister at the court of Hesse-Cassel, which post he continued to hold till 1857, when he retired from professional life. He died in 1859. S.'s musical works include seven operas—*Faust*, *Jessonda*, *Zemira und Azor*, *Der Zweikampf der Geliebten*, *Der Berggeist*, *Peter von Albano*, and *Der Alchymist;* three oratorios, *Die letzten Dinge*, *Des Heiland's letzte Stunden*, and *Der Fall Babylons;* various masses, psalms, and hymns, six grand symphonies, four overtures, besides nonettes, quartetts, violin concertos, sonatas for violin and harp, fantasias, and rondos. *Die letzten Dinge*, or Last Judgment, is a very grand and very attractive work; so also is *Der Fall Babylons*, first produced at a Norwich musical festival. Of his operas, the most esteemed are *Faust* and *Jessonda*, the latter remarkable for its successful embodiment of the spirit of oriental poetry. His songs are rather deficient in broad and decided melody; but his instrumental works occupy a very high place in the estimation of musicians, more especially the C minor symphony, and the symphony known as *Die Weihe der Töne*. As a violinist, S.'s purity of tone and high finish have never been surpassed, and his *Violinschule* is the best and most complete work on violin playing ever written.—See *The Autobiography of L. Spohr;* translated from the German (Lond. 1864).

SPOLE'TO (Latin, *Spoletium*), a city of Italy, province of Umbria, is situated on a rocky hill, 61 miles north-north-east of Rome. Pop. (1872) 20,748. It is commanded by a strong citadel, which is built on a separate hill, divided from that on which the town stands by a deep gorge, crossed at an immense height by a bridge and aqueduct. The streets are steep, narrow, and dirty. S. has a fine cathedral, built in the time of the Lombard dukes, and containing many interesting works of art. The churches of St Dominico, San Giovanni, the collegiate church of San Pietro, and the palace of the ancient dukes of S., are also worthy of being mentioned. The ancient *Spoletium* had its origin in a Roman colony which was planted here about 240 B. C.; and during the second Punic War, Hannibal is said to have been repulsed by the colonists in an assault which he made on the town (217 B. C.), after the battle of Thrasymene. Under the Lombard dukes, it became the capital of an independent duchy. In 1860, it was taken by the Italians from a body of Irish mercenaries in the service of the pope, and now forms a part of the Kingdom of Italy. S. contains many interesting Roman remains, as also a ruin which goes under the name of the Palace of Theodoric. It has manufactures of woollens and hats.

SPO'NDIAS. See HOG PLUM.

SPONGE (*Spongia*), a genus which originally included all the numerous genera and species of the family *Spongiadæ*, all of which are still commonly spoken of by naturalists as sponges, although in its more popular sense that term is limited to a few kinds, or to their fibrous framework. The sponges are creatures of very low organisation, concerning which there has been much difference of opinion, whether they ought to be referred to the animal or to the vegetable kingdom. Naturalists are now generally agreed in regarding them as animals. They are, perhaps, the very lowest of *Protozoa*. They are attached, like plants or zoophytes, to rocks or other substances in water; most of them are marine. They consist of a glairy or gelatinous substance (*Sarcode*), and of a framework, which is often formed of a horny, elastic substance (*Keratose*), in fibres growing from a broad base, anastomosing and intimately connected together, or consists of calcareous, or more generally,

Living Sponge.

siliceous spicules, imbedded in the gelatinous mass, and exhibiting great variety of form and arrangement. These spicules do not consist of mere mineral matter, but in part of animal matter, by the growth of which their term is determined. They are most beautiful microscopic objects, and

spicules of different forms are sometimes found in the same species, sometimes lying close together in bundles, sometimes straight or slightly curved, sometimes in the shape of needles pointed at one end, or at both; sometimes of needles radiating from a centre; whilst some have a head at one end, like a pin, some have grapnel-like hooks at the ends. Some of the species with horny framework, have spicules imbedded in it; some have them implanted in the fibres; some are destitute of them. There is a beautiful West Indian species, *Dictyocalyx pumiceus*, in which the siliceous matter becomes itself a fibrous network, and is so fine and transparent as to resemble spun glass. In a living state, many sponges exhibit lively colours, from the presence of some colouring matter, or from iridescence. Their gelatinous substance has a fish-like odour. If detached portions of it are examined under the microscope, variable processes may be seen in motion, as in the *Amœba* or *Proteus* (q. v.). Sponges may be regarded as aggregations of *Amœbæ*, or rather of *Infusoria flagellata* (Clark), but individuality is soon lost when individuals of the same species are brought together. They coalesce into one. And if a sponge is divided by the knife, the parts, placed together, very quickly reunite, even if not in their former relation to each other. But parts of different species never unite in this way, however closely placed together. Sponges have never been observed to exhibit irritability. At first, they are like separate *Amœbæ;* but after they become fixed to a spot, increase by a kind of gemmation, like zoophytes. They assume very various forms, which, as well as the peculiarities in the structure of the framework, are characteristic of the different genera and species. Some are nearly globular; some cup-shaped, top-shaped, conical, cylindrical, thread-like, &c.; some are simple, and some branched.

The surface of a living sponge is generally covered with minute pores, through which water is imbibed, carrying with it both the air and the organic particles necessary for the support of life. The pores are supposed to be permanent in many of the sponges, and the currents which enter through them to be produced by cilia, although these have as yet been detected only in a few species. But in those of the very lowest organisation, the pores seem to be formed for the occasion, just as the *Amœba* opens anywhere to admit food within its substance. In *Spongilla fluviatilis*, a small fresh-water species found in Britain, the opening and closing of each pore occupies less than a minute, and the pores do not open simultaneously, but in irregular succession, and apparently never again in precisely the same spot. No trace of the pore remains for an instant after its closing, nor is there any indication of the point where a new one is to open. The water which enters by the pores passes out of some sponges by a single orifice, which serves for the whole mass; others have numerous orifices (*oscula*) which are permanent, and are much larger than the pores by which the water is imbibed, the whole mass being pervaded by canals which lead from the pores to these orifices, from which, under the microscope, a constant discharge of water may be seen taking place, minute opaque particles being carried along with its current. These particles are not only fæcal matter, but gemmules and ova.

A B

Structure of *Grantia compressa*:

A. portion shewing general arrangement of triradiate spicules and intervening tissue, magnified; B. small portion highly magnified, shewing ciliated cells.—From Carpenter *On the Microscope*.

Reproduction takes place both by gemmation and by true ova. Many of the gemmules go to increase the sponge-mass; but the greater part finally become detached, and are carried out into the water, to settle down in a new locality. Mr Huxley has detected true ova and sperm-cells imbedded in the substance of sponges.

The sponges employed for domestic and other purposes derive their value from the elasticity and compressibility of their fibrous framework, divested of the glairy substance, and its power of imbibing fluids. The absence of spicules is essential to a useful sponge. The kinds fit for use are found in the seas of warm climates. Some small species of sponge live at great depths. One has been brought up in the Gulf of Macri from a depth of 185 fathoms. Numerous species of sponge are very abundant on many parts of the British coasts.

Fossil remains of sponges are found in many rocks, and of horny, fibrous kinds, as well as of those with calcareous or siliceous framework.

Several species of sponge are in use for economical purposes. Two species are chiefly brought from the Levant, and a very inferior one from the West Indies and coast of Florida. The trade in sponge is very considerable; it is carried on chiefly by the Turks and the inhabitants of the Bahama Islands. The number of men employed in the Ottoman sponge-fishery is between 4000 and 5000, forming the crews of about 600 boats. These boats find their chief employment on the coasts of Candia, Barbary, and Syria. The sponge is obtained by diving, the diver taking down with him a flat piece of stone of a triangular shape, with a hole drilled through one of its corners; to this a cord from the boat is attached, and the diver makes it serve to guide him to particular spots. When he reaches the growing sponges, he tears them off the rocks, and places them under his arms; he then pulls at the rope, which gives the signal to his companions in the boat to haul him up. The value of sponges collected in Greece and Turkey is from £90,000 to £100,000 annually. The Greeks of the Morea, instead of diving, obtain sponges by a pronged instrument; but the sponges thus collected are torn, and sell at a low price. The best sponges are obtained on detached heads of rock in 8 or 10 fathoms water.

The sponges of the Bahamas and other West Indian islands are of a larger size and coarser quality; but large quantities are gathered; and about 215,000 lbs., worth £17,000, are sent annually to Great Britain. The sponges are torn from the rocks by a fork at the end of a long pole. To get quit of the animal matter, they are buried for some days in the sand, and then soaked and washed.

The domestic uses of sponge are familiar to every one. It is also of great value to the surgeon, not only for removing blood in operations, but for checking hæmorrhage. Burnt sponge was once a

valued remedy for scrofulous diseases and goitre; but iodine and bromine, from which it derives all its value, are now administered in other forms.

SPO'NSOR (Lat. one who promises), the name given in theological use to a Godfather or Godmother (q. v.). The name is derived from the circumstance, that in baptism or confirmation, and especially in infant baptism, the sponsor is understood to make certain promises or engagements in the name, and on the part of the person baptised or confirmed. The idea of sponsorship is entirely rejected not only by Baptists, but generally also by Presbyterians and Independents.

SPONTANE'ITY, the name for the doctrine, referring to the Human Mind, that muscular action may, and does, arise from purely internal causes, and independent of the stimulus of sensations. It had long been the tacit assumption in Mental Philosophy, that we are never moved to action of any kind, except under the stimulation of some feeling, some pleasure or pain, or some end in view. To this is now opposed the doctrine of the Spontaneous commencement of movements under certain circumstances; which, however, does not exclude, but only supplements, the operation of the feelings in stimulating movements, as in the ordinary course of voluntary action. The doctrine supposes that the nerve-centres, after repose and nourishment, acquire a fulness of vital energy, which discharges itself in the play of movement, without any other occasion or motive; the addition of a feeling, or end, enhances and directs the activity, but does not wholly create it.

Of the various proofs and illustrations of Spontaneity, perhaps the most striking is that furnished by the movements of young animals of the active species. A young dog or kitten shews a degree of activity out of all proportion to any feeling to be gratified, or any end to be served; we can interpret it only as internal energy seeking vent, irrespective of the pursuit of pleasure or the avoidance of pain—in other words, the action of the will. When the accumulated energy is expended, the animal falls back into a state of repose, and is then roused only by the stimulus of sensation. The state called 'freshness' in a horse, for example, is a state of superabundant and irrepressible activity. Children go through the same phase: after rest or confinement, they burst forth incontinently into some form of active excitement, of which a part may be considered as pure spontaneity, while part may be owing to sensation.

The doctrine is well fitted to express the difference between the active and the sensitive temperaments; for, if it were true that action is in proportion to the stimulation of the feelings, the most susceptible characters would be the most active. But, in point of fact, the active temperament is manifested by a profusion of activity for its own sake, with little circumspection or regard to consequences; and constitutes the restless, bustling, roughshod, energetic, and enterprising disposition of mind, as seen in sportsmen, soldiers, travellers, &c.

The explanation of the growth of the Will (q. v.), or voluntary power, involves the spontaneous beginning of movements.—See Bain on *The Senses and the Intellect*, 2d edit., p. 76.

SPONTA'NEOUS COMBU'STION is a phenomenon that occasionally manifests itself in mineral and organic substances. The facts connected with the spontaneous ignition of *mineral* substances are well known to chemists, and some of them have been already described in the article PYROPHORUS (q. v.). Ordinary charcoal does not undergo combustion in air under a temperature of 1000°, but in some states it is liable spontaneously to acquire a temperature which may lead to unexpected combustion. Thus, lamp-black impregnated with oils, which contain a large proportion of hydrogen, gradually becomes warm, and inflames spontaneously. According to M. Aubert, Chevallier, and other French observers, recently-made charcoal, in a state of fine division, is liable to be spontaneously ignited without the agency of oil; but we are not aware that this phenomenon has been observed in this country. There have been many instances of the spontaneous ignition of coals containing iron pyrites, (q. v.) when moistened with water. The pyrites which most readily give rise to spontaneous combustion are those in which the protosulphide is associated with the bisulphide of iron; and these occur in the Yorkshire coals from Hull, and in some kinds of South Wales coal. Sulphur has no tendency to spontaneous combustion, but Dr Taylor refers to an instance that came to his own knowledge, in which there was reason to believe that the vapour of bisulphide of carbon in an india-rubber factory was ignited by solar heat traversing glass. Phosphorus, when in a dry state, has a great tendency to ignite spontaneously, and it has been observed to melt and take fire (when touched) in a room in which the temperature was under 70°. The ordinary lucifer-match composition is luminous in the dark, in warm summer nights, which shews that oxidation, and therefore a process of heating, is going on. Hence, large quantities of these matches kept in contact may produce a heat sufficient for their ignition. 'I have seen them ignite,' says Dr Taylor, 'as a result of exposure to the sun's rays for the purpose of drying.'—*Principles and Practice of Medical Jurisprudence*, 1865, p. 603.

From these cases occurring in the mineral kingdom, we pass to the consideration of spontaneous combustion in *organic* substances. Passing over the accidents that may result from the admixture of strong nitric or sulphuric acid with wool, straw, or certain essential oils, and which, if they occur, are immediate and obvious, we have to consider the cases in which, 'without contact with any energetical chemical compounds, certain substances—such as hay, cotton and woody fibre generally, including tow, flax, hemp, jute, rags, leaves, spent tan, cocoa-nut fibre, straw in manure-heaps, &c.—when stacked in large quantities in a damp state, undergo a process of heating from simple oxidation (eremacausis) or fermentation, and, after a time, may pass into a state of spontaneous combustion.'—Taylor, *op. cit.* p. 606. There is undoubted evidence that hay and cotton in a damp state will occasionally take fire without any external source of ignition. Cotton impregnated with oil, when collected in large quantity, is especially liable to ignite spontaneously; and the accumulation of cotton-waste, used in wiping lamps and the oiled surfaces of machinery, has more than once given rise to accidents, and led to unfounded charges of incendiarism. Dr Taylor relates a case in which a fire took place in a shop 'by reason of a quantity of oil having been spilled on dry sawdust.' According to Chevallier, vegetables boiled in oil furnish a residue which is liable to spontaneous ignition; and the same chemist observes that all kinds of woollen articles imbued with oil, and collected in a heap, and hemp, tow, and flax when similarly treated, may ignite spontaneously. In the case of Hepburn *v.* Lordan, which came before Vice-chancellor Wood in January 1865, and was carried by appeal before the Lords Justices in the following month, an attempt was made to prove that wet jute was liable to undergo spontaneous combustion; and the great fire at London Bridge in 1861 was referred

to the spontaneous combustion of jute in its ordinary state. With regard to the latter hypothesis, Dr Taylor remarks that it is wholly incredible, and from experiments which he made for the defendants in the above lawsuit, and on other grounds, he holds that there is no evidence of moist jute undergoing spontaneous combustion; but, he adds, although no cases are recorded, it is probable that jute, cocoa-nut fibre, and linen and cotton rags, imbued with oil, might undergo this change. Dry wood is supposed by Chevallier and some other chemists to have the property of igniting spontaneously. Deal which has been dried by contact or contiguity with flues or pipes conveying hot water or steam at 212°, is supposed to be in a condition for bursting into flame when air gets access to it; and the destruction of the Houses of Parliament, and many other great fires, have been ascribed to this cause; but from the experiments of Dr Taylor (*op. cit.*, p. 615) this view must be regarded as untenable.

It is still an open question whether such organic nitrogenous matters as damp grain or seeds of any kind ever undergo spontaneous combustion. In a case recorded in the *Annales d'Hygiène* for 1841, MM. Chevallier, Ollivier, and Devergie drew the conclusion that a barn had caught fire from the spontaneous combustion of damp oats which were stored in it. No such cases are known to have occurred in this country.

The subject of the article is of extreme importance, not only because it may cause great destruction of life and property, but because it may lead to unjust charges of incendiarism.—For further details regarding it, the reader is referred to Graham's 'Report on the Cause of the Fire in the *Amazon*,' in the *Quarterly Journal of the Chemical Society*, vol. v. p. 34; to the article 'Combustion' in Watts's *Dictionary of Chemistry*, vol. i.; and to the elaborate chapter on this subject in Taylor's *Principles and Practice of Medical Jurisprudence.*

SPONTANEOUS COMBUSTION OF THE HUMAN BODY. In medico-legal works, cases are recorded, generally of a somewhat ancient date, in which it was supposed that the body was either spontaneously consumed by inward combustion, or acquired such extraordinary combustible properties as to be consumed when brought into contact with fire. The following is the first of one of the cases on record. It rests on the authority of Le Cat, a distinguished surgeon of his time, and is stated to have occurred at Rheims in 1725. The remains of a woman named Millet were found burned in her kitchen, about eighteen inches from the open fireplace. Nothing was left of the body, except some parts of the head, of the legs, and of the vertebræ. Suspicion was excited against the husband, and a criminal inquiry was instituted; but learned experts reported that the case was one of spontaneous combustion, and the prisoner was acquitted. The facts are explicable on the supposition, that the clothes of the deceased woman were accidentally ignited; and although the almost complete destruction of the body appeared to the medical men of that time to be inconsistent with the ordinary effects of fire, subsequent observations have shewn that this is an error. In reference to this case, Liebig observes that it is easy to see that the idea of spontaneous combustion arose at a time when men entertained entirely false views on the subject of combustion, its essence, and its cause. What takes place in combustion generally has only been known since the time of Lavoisier (about 84 years ago), and the conditions which must be combined in order that a body should continue to burn, have only been known since the time of Davy, or for little more than half a century. From the time when the case of Millet occurred to the present day, probably somewhat over 50 supposed cases have been recorded. (In an article published on the subject by Dr Frank of Berlin in 1843, 45 cases are adduced.) From an analysis of all the cases on record up to 1851, Liebig arrives at the conclusion that the great majority agree in the following points: '1. They took place in winter. 2. The victims were brandy-drinkers in a state of intoxication. 3. They happened where the rooms are heated by fires in open fireplaces and by pans of glowing charcoal, in England, France, and Italy. In Germany and Russia, where rooms are heated by means of closed stoves, cases of death ascribed to spontaneous combustion are exceedingly rare. 4. It is admitted that no one has ever been present during the combustion. 5 None of the physicians who collected the cases, or attempted to explain them, has ever observed the process, or ascertained what preceded the combustion. 6. It is also unknown how much time had elapsed from the commencement of the combustion to the moment when the consumed body was found.' —*Letters on Chemistry*, 3d ed., 1851, p. 282. Out of the 45 cases collected by Frank, there are only three in regard to which it is assumed that combustion took place when no fire was in the neighbourhood; and Liebig distinctly shews that these three solitary cases are totally unworthy of belief. With regard to the other cases, the writers who record them do not deny the presence of fire, but assume that the body was ignited by the fire, and then burned on like a candle or a bundle of straw, under similar conditions, till nothing but ashes or charcoal was left. These writers maintain that excess of fat, and the presence of brandy in the body, induce an abnormal condition of easy combustibility; but Liebig shews, by numerous illustrations, the utter fallacy of this view; and adds, as further evidence, 'the fact that hundreds of fat, well-fed brandy-drinkers do not burn, when by accident or design they come too near a fire. It may with certainty be predicted, that so long as the circulation continues, their bodies would not take fire, even if they held a hand in the fire till it was charred.' Spontaneous combustion in a living body is (he adds) absolutely impossible. Notwithstanding the wide promulgation of Liebig's views, the belief in the possible occurrence of spontaneous combustion seems not yet to have disappeared. In 1847, the body of a man, aged 71, and who was neither fat nor a drunkard, was found in bed in a state of combustion. Dr Nasson, who was commissioned to investigate the case, reported that the burning must have resulted from some inherent cause in the person —probably roused into activity by a hot brick that was placed at his feet; and Orfila is reported to have coincided in this opinion. This case is reported in the *Gazette Médicale*, September 4, 1847. On the 13th of June 1847, the Countess of Goerlitz was found dead in her bedroom, with the upper part of her body partly consumed by fire. The head was a nearly shapeless black mass, with the charred tongue protruding from it. The physician who was consulted could suggest no other explanation than that the body of the countess must have taken fire spontaneously, and not even by ignition of her dress by a candle. On this evidence, she was buried; but circumstances having led to the suspicion that she had been murdered by her valet Stauff (who had been detected in attempting to poison the count), her body was exhumed in August 1848, fourteen months after her death, and was subjected to a special examination by the Hesse Medical College, who reported that she had not died from spontaneous combustion. The case was then referred to Liebig and Bischoff, and their report was issued in

March 1850, when Stauff was put upon his trial. They found no difficulty in concluding that the body was wilfully burned *after death*, for the purpose of concealing the murder (either by strangulation or a blow on the head), which had been previously perpetrated. The prisoner was convicted, and subsequently confessed that he had committed the murder by strangulation, as indeed the protruded tongue might have suggested. Since that date, there has not been any case of alleged spontaneous combustion.—On this subject, the reader is referred for much curious and interesting matter to the various articles on 'Spontaneous Combustion' in the Medical Dictionaries and Encyclopædias; to Dupuytren's *Leçons Orales*, p. 513; to Liebig's *Letters on Chemistry*; and to Taylor's *Principles and Practice of Medical Jurisprudence*.

SPONTOO'N, a weapon bearing resemblance to a halberd, which, prior to 1787, was borne instead of a half-pike by officers of British infantry. It was a medium for signaling orders to the regiment. The spontoon planted in the ground commanded a halt; pointed backwards or forwards, advance or retreat; and so on.

SPOOL, in Spinning, a wooden reel for winding yarn upon. In sewing and lace-making machines, the spools are of metal, and their forms vary according to the requirements of the machine.

SPOO'NBILL (*Platalea*), a genus of birds of the Heron family (*Ardeidæ*), much resembling storks both in their structure and their habits, but distinguished by the remarkable form of the bill, which is long, flat, broad throughout its whole length, and much dilated in a spoon-like form at the tip. The species are not numerous, but are widely distributed. The only European species is the WHITE S. (*P. leucorodia*), rare in Britain, although in former times, before the draining of the fens in England, it was a more frequent summer visitor. It is common in Holland, in marshy districts throughout the northern parts of Europe and Asia in summer, and in the salt marshes of the coast of Italy in winter. It also inhabits Africa, and its range extends over the whole of that continent. It is gregarious, and the flocks of spoonbills generally make their nests in woods, in the tops of lofty trees. It is considerably smaller than the Common Heron. Its colour is white, slightly tinged with pink; the bill and legs are black. A curious convolution of the windpipe, in the form of the figure 8, is found on dissection in the adult S., but does not exist in the young. The flesh of the S. is said to be tender and of good flavour. The S. is easily tamed, is quiet and inoffensive, and feeds readily on any offal.—The ROSEATE S. (*P. ajaja*) is an American species; very abundant within the tropics, and found in the most southern parts of the United States. It is nearly equal in size to the White S., which it resembles in its habits. It is a beautiful bird, with plumage of a fine rose-colour, of which the tint is deepest on the wings; the tail-coverts crimson.

SPO'RADES. See ARCHIPELAGO and TURKEY.

SPORA'DIC (Gr. scattered) is a term applied to any disease that is naturally epidemic or contagious, when it attacks only a few persons in a district, and does not spread in its ordinary manner. The conditions on which the occurrence of epidemic or contagious diseases in a sporadic form depend are unknown. Amongst the diseases which occur in this form may be especially mentioned catarrh, cholera, dysentery, measles, scarlatina, and small-pox.

SPORE, in Botany, may be called the *seed* of a cryptogamous plant, as it serves the same purpose of reproduction as the seed of a phanerogamous or flowering plant, and after remaining for a time in a state of rest, is developed into a new plant on the occurrence of the necessary conditions. A spore, however, differs very much from the seed of a phanerogamous plant, as it always consists of a single cell, and therefore does not contain any *embryo* or rudiment of the future plant. In its formation, it corresponds rather with the grains of pollen in the anther of a flower. Spores are small, often so minute as to be invisible to the naked eye—many of them extremely minute, so that they may be wafted about unperceived. This, indeed, might be expected from the very small size of many of the cryptogamic plants themselves, as moulds and many other fungi. But even the spores of the largest ferns are very small. Spores often remain capable of germination for many years, and they seem to be capable of enduring much drought without destruction. They seem to germinate indifferently from any part of their surface, in which they differ essentially from the seeds of phanerogamous plants. In the parent plant, they are either scattered singly, or are united in a fruit-like envelope, which is generally known as a *Sporangium*, or *Spore-case*. In some plants, they are united in definite numbers, as of four (a *tetraspore*), surrounded by an envelope (*perispore*, or *sporidium*). The peculiar reproductive organ, which in some cryptogamous plants produces the spores, is called a *sporocarp*, or a *sporophore*. In many plants, as in mushrooms, the production of spores belongs exclusively to a part of the plant called the *hymenium*.

SPORTS, BOOK OF, the name popularly given to a Declaration issued by James I. of England in 1618, to signify his pleasure that on Sundays, after divine service, 'no lawful recreation should be barred to his good people, which should not tend to the breach of the laws of his kingdom and the canons of his church.' The sports specified were dancing, archery, leaping, vaulting, May-games, Whitsun-ales, morrice-dances, and the setting up of May-poles. The occasion of this proclamation was the conduct of some Puritan authorities in Lancashire, who, in illegally suppressing, instead of regulating, the customary recreations of the common people, had excited much discontent, and increased the influence of the Roman Catholics by giving a repulsive aspect to the Reformed religion. Although the Declaration was ordered to be read in the parish churches of the diocese of Chester, this order was not enforced, and the king's design was allowed to drop. Among the excepted unlawful sports were bear-baiting, bull-baiting, bowling, and interludes. Nonconformists and others not attending divine service at church were prohibited from joining in the sports, nor was any one allowed to go out of his own parish for that purpose, or to carry offensive weapons. By republishing this Declaration in 1633, and enforcing with great severity the reading of it by the clergy in their churches (see SABBATH), Charles I. and Laud excited among the Puritans a degree of indignation which contributed not a little to the downfall of the monarchy and the church. In 1644, the Long Parliament ordered all copies of it to be called in and publicly burned.—Heylin's *Hist. of the Sabbath and Life of Laud*, Fuller's *Church History*, D'Israeli's *Life of James I.*, Southey's *Book of the Church*, Hallam's *Constitutional History of England*, and Cox's *Literature of the Sabbath Question*.

SPOTTISWOOD, JOHN, Archbishop of St Andrews, son of John Spottiswood, Superintendent of Lothian, was born in the year 1565. He was educated at the university of Glasgow, and on his

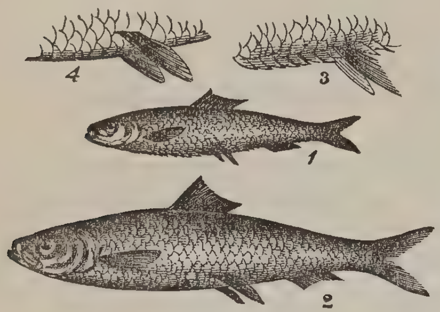
father's death, succeeded him as Parson of Calder. In 1601, he attended the Duke of Lennox as chaplain, when that nobleman was sent as ambassador to France by King James VI. When James succeeded to the English crown, S. accompanied him on his journey to London, and, soon after that event, on the death of Archbishop James Beaton, was appointed to the see of Glasgow. He was chosen Moderator of the General Assembly of the Scottish Church, which met at Glasgow in 1610, and completed the establishment of episcopal government, which James had laboured so long to accomplish. In October of that year, he was, along with the bishops of Brechin and Galloway, consecrated at London House by the Bishop of London and other English prelates. In 1615, he took a leading part in the examination of John Ogilvie, a Jesuit priest, who was apprehended at Glasgow, and hanged for refusing to disown the temporal power of the pope. The share he took in this matter was most discreditable to the archbishop. In the course of the same year, he was translated to the see of St Andrews. As primate of the Scottish Church, S. had now the chief management of ecclesiastical affairs, and great influence also in the civil government, and his rule was marked by uniform ability, and, with rare exceptions, by prudence and moderation. He presided at the Assembly which met at Perth in 1618, and sanctioned the five points of ecclesiastical discipline known as the Perth Articles. He was as much in favour with King Charles I. as he had been with King James, and at the coronation of that sovereign at Holyrood in 1633, he placed the crown on his head and anointed him. In 1635, S. was made Chancellor of Scotland, a dignity which no churchman had held since the Reformation; but in accepting an appointment so invidious to the nobles, he did not act with his usual discretion. He reluctantly entered into the king's unwise measures for the introduction of a liturgy into Scotland, and became one of the chief objects of popular dislike when the Covenanters acquired the ascendency. He soon found it necessary for his safety to retire to England, and in the end of 1638, at the king's request, he resigned the chancellorship. He protested against the lawfulness of the General Assembly which met at Glasgow in November of the same year, and was deposed and excommunicated by that body for alleged offences, which, so far as his private character was concerned, were improbable in themselves, and supported by no evidence whatever. The archbishop did not long survive the overthrow of the polity which it had been the work of his life to build up. He died at London on the 26th of November 1639, being then in the 74th year of his age. He had expressed a wish to be buried at Dairsie in Fife, where he had rebuilt the church after the English model, but this was found impracticable, and he was interred in Westminster Abbey. The writings of S. are his well-known *History of the Church of Scotland*, first published in 1655; a Sermon preached at the meeting of the Perth Assembly of 1618, which was published by Bishop Lindsay in 1621 in his account of the proceedings of that Assembly; and a Latin treatise, *Refutatio Libelli de Regimine Ecclesiæ Scoticanæ*, written in answer to a tract of Calderwood's, and published in 1620. The chief authorities for the biography of the archbishop are the Life ascribed to Bishop Duppa, prefixed to the folio editions of his *History*, and the Life by Bishop Russell, prefixed to the Spottiswood Society edition of the same work.

SPRAIN. A sprain or *strain* is a term employed in Surgery to designate a violent stretching of tendinous or ligamentous parts with or without rupture of some of their fibres. Sprains are very frequent in all the joints of the upper limbs, especially in the wrist and the articulations of the thumb. In the lower extremity, the ankle is the joint by far the most frequently affected; and this is accounted for anatomically by the small size of the articular surfaces, the great weight the astragalus (the bone presenting the lower articular surface) has to support, and the unyielding nature of the lateral ligaments. In slight sprains of this joint, the ligaments are only stretched or slightly lacerated, but in more severe cases they may be completely torn through. Sprains of the ankle are sometimes mistaken for fractures, and *vice versâ;* and the two injuries may co-exist. The pain and swelling sometimes make an accurate diagnosis difficult, especially if the patient is not seen for some time after the accident; and if any doubt exists, the case should be treated as for the more severe injury, since it is better that the treatment should be prolonged than that the patient should be maimed; and fortunately, that which is the proper treatment of a fracture is the best that can be employed for a sprain. Sprains of the knee are not uncommon, and are characterised by great swelling from effusion of fluid within the joint. Sprains of the back are not unfrequent accidents, and are the most serious of any, but in most cases it may be anticipated that after confinement in bed or on a sofa for two or three weeks, and with proper treatment, the patient will be able to walk, although he may feel stiffness and pain for several weeks longer. The treatment of sprains generally must be regulated by their severity. In a severe sprain, attended with much pain and inflammation, leeches should be applied, followed by hot-water fomentations, or the application of a hot linseed-meal poultice. In slighter cases, rest and cold lotions constitute sufficient treatment. In all cases of sprain of the extremities, thin pasteboard splints placed on the outer and inner surfaces of the joint, over a wet bandage previously laid round it, afford support to the part, and comfort to the patient. In sprains of the back, more decided antiphlogistic or lowering measures are required. 'After an active mercurial purge, a dose or two of Dover's Powder may be given, with salines at intervals. The diet ought to be spare. In those of vigorous constitution, the abstraction of blood may be required. Afterwards, nothing will conduce more to the comfort of the patient than well-managed fomentation of the back. Amendment will be denoted by the patient's turning in bed more freely, and seeking to sit up. At that period, stimulating liniments, or the application of the compound tincture of iodine, will be called for. When able to walk, he will be benefited by a warm plaster to his loins.'—Shaw on 'Injuries of the Back,' in Holmes's *System of Surgery*, vol. ii. p. 202.

SPRAINS, or STRAINS, are very common amongst horses, owing to the severe exertions required of them, often whilst they are young, and unprepared for such work. Various muscles, ligaments, and tendons are liable to strain, but none more frequently than the large tendons passing down the back of the fore-limbs. In slight cases, cold water continuously applied for several hours gives relief; but in all serious cases, diligent fomentation with water about the temperature of 100° is preferable; or the injured part may be swathed in a thick woollen rug, kept constantly moist and warm by frequent wetting with the hot water. Perfect rest is essential, and in order to insure the relaxation of the large tendons of the horse's limbs, he may in bad cases be kept slung for several days. Blisters, hot oils, firing, and all such irritants, are on no account to be used until the inflammation

subates, and the part becomes cool, and free from tenderness. Such remedies are then useful for causing the reabsorption of swelling, and perhaps also for invigorating the weakened part.

SPRAT (*Harengula sprattus*, formerly *Clupea sprattus*), a fish of the family *Clupeidæ*, very abundant on many parts of the British coast, and elsewhere in the northern parts of the Atlantic. It is smaller than the herring, being only about six inches in length when full grown, but much resembles it. It is, however, easily distinguished by the serrated belly, and by the position of the fins, the ventral fins beginning immediately beneath the first ray of the dorsal fin, and not beneath the middle of it, as in the herring and pilchard. Another easily observed distinction is the want of axillary scales to the ventral fins, which both the herring



Sprat and Herring:
1, sprat; 2, herring; 3, belly of sprat; 4, belly of herring.

and pilchard have. The dentition is also different, and on this account Valenciennes has constituted, for the S. and a number of other species, the new genus *Harengula*, characterised by having teeth on the jaws, tongue, palatines, and pterygoids, but no teeth on the vomer. The herring has teeth on the vomer. Valenciennes states also that the S. has only 48 vertebræ, whilst the herring has 56. Notwithstanding all this, an old opinion has recently been revived, and urged with some pertinacity on public attention, that the S. is the young of the herring, which, therefore, it is injurious to a more important fishery to capture. Except that it is not common to find sprats full of roe, nothing has been stated in support of this notion more to the purpose than that the serratures of the belly may possibly be a provision for the growth of the fish; a provision to which it may be remarked that nothing analogous appears in any province of nature. Nor is it wonderful that many sprats may be examined without roe being found, as the greater part of those taken on the British coasts have not attained their full size. Sprats abound especially on the coasts of Norfolk, Suffolk, Essex, and Kent in November and several following months. The net used for their capture has smaller meshes than the herring-net. Drift-net fishing is practised as for herring, and a method called *stow-boat* fishing, in which a large bag-net is suspended between two horizontal beams beneath the boat, and about a fathom from the bottom of the water; ropes from the ends of the upper beam enabling the fisherman in the boat to keep the mouth of the bag always open and against the tide. Vast quantities of sprats are taken in this way, so that they are used as manure by farmers, although London is also very largely supplied with them, and being sold at a very cheap rate, they are a favourite article of food of the poorer classes. The Firth of Forth also produces sprats—in Scotland, called *garvies*—so abundantly that they are sold both in Edinburgh and Glasgow by measure, and cheaper than any other kind of fish. But there are many parts of the British coast where the S. is rare, some of these being parts where the herring is plentiful. Notwithstanding its cheapness, the S. is a very fine fish, of flavour quite equal to the herring, although decidedly different. Dried sprats are a very common article of provision, and sprats are also sometimes salted. The *kilkies* brought from Riga and other ports on the Baltic, are sprats cured with spices; and many of the boxes of *Sardines* which are sent to market from the west coast of France, are really filled with sprats. The value of the S. does not seem to be as yet fully appreciated in Britain.—Very closely allied to the S. is another fish (*Harengula latulus*), the *Blanquette* of the French, which is caught in great abundance on some parts of the west coast of France.—Other species of *Harengula* are found in other seas. One of them (*H. humeralis*), which abounds in the West Indies, and southwards as far as Rio Janeiro, is much esteemed, but becomes dangerous at certain seasons, from some unknown cause.

SPREAD EAGLE. See EAGLE.

SPREE, a river of Prussia, rises near Ebersbach in the east of Saxony, on the borders of Bohemia, and after an irregularly winding, but generally north and north-western course of 220 miles, falls into the Havel (q.v.) at Spandau. It has all the peculiarities of a stream flowing through a low and marshy region—abounding in fish, and frequently expanding into lakes, the largest of which are the *Schwielochsee* and *Müggelssee*. Its banks are flat, sometimes sandy and wooded, and sometimes rich in meadow-pastures. It becomes navigable for small craft at Kosenblatt. The principal towns past or through which it flows are Bautzen, Spremberg, Kottbus, Lübben, Beeskow, and Berlin. Its trade is very considerable. By the Friedrich Wilhelm's or Müllrose Canal, it is connected with the Oder.

SPRING, a stream of water issuing from the earth. The source of springs is the rain and snow that falls from the clouds. Very little of the water precipitated in any district finds its way immediately by rivers to the sea; the great proportion is either evaporated from the surface of the earth, and, reabsorbed by the atmosphere, is employed by plants and animals, or sinks into the earth. All loose soils and gravels greedily absorb water, which descends until it meets with a stratum through which it cannot penetrate. A pit dug into the water-charged soil would speedily fill itself by draining the water from the soil. All rocks contain water; some retain it by capillary attraction, like a sponge, others hold it merely mechanically, and easily part with it. Chalk will absorb and retain one-third of its bulk of water; and sand, on the other hand, while it will absorb as much, will part with nearly the whole amount to a well dug in it. Argillaceous deposits and compact rocks are barriers to the passage of water, and cause the superincumbent pervious strata to become water-logged, where there is no outlet. Sometimes the edges of the strata are exposed on the sides of a valley, and permit the free escape of the contained water, which pours from them over the neighbouring land. But rents and fissures, as well as inequalities on the surface of the impervious beds, give the water a circumscribed course, and cause it to issue in springs.

The water, as it percolates through the earth, always becomes more or less charged with foreign

matter, owing to its solvent property. Carbonate, sulphate, and muriate of lime, muriate of soda, and iron, are the most common impurities in spring-waters; magnesia and silica also frequently occur. These substances, from the evaporation of part of the water, or the escape of the carbonic acid gas, by which so large a quantity is often held in solution, are frequently deposited on the margins of the springs, or in the courses of the streams flowing from them. Such deposits are found in all so-called petrifying springs; and the hot wells of Iceland and the Azores are surrounded with basins formed of siliceous sinter which has been derived from the water. When the foreign ingredients have medicinal qualities, the springs are known as Mineral Waters (q. v.).

Springs are either associated with the superficial strata, or rise from a considerable depth. *Surface-springs* occur where the absorbent surface-deposits rest on an impervious bed, which prevents the further

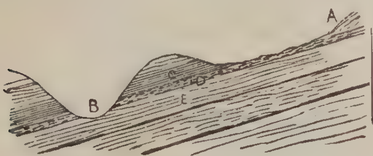


Fig. 1.

downward progress of the water, or where the beds through which the water flows are near the surface, as shewn in fig. 1, where C and E are impervious clay-beds, and D is a bed of sand or gravel, which in the upper portion is exposed on the surface, or is only overlaid by loose soil, and after being covered for some distance by the clay-bed C, makes its appearance again at B, where the valley cuts it through: here the water collected over the area, A, is discharged. Surface-springs, depending as they do so directly on the rain for supplies, are very variable in the amount of water they deliver. They frequently fail entirely in the summer, and always after great droughts. Their temperature varies with that of the district where they exist, being warm in summer, and cold in winter, as they do not penetrate below that plane in the earth's crust which is affected by the seasonal changes in temperature.

When the bed which forms the reservoir for the spring is at such a distance from the surface as to be beyond the zone of season changes, and yet within that which is influenced by the climate, the water has a temperature equal to the mean temperature of the locality where it springs. Such springs have generally a large area for the collection of the superficial water, and are consequently regular in the quantity of water they give out. They are brought to the surface by means of faults. The celebrated Well of St Winifred at Holywell, in Flintshire, rises through a fault in the Coal Measures. It discharges at the rate of about 4400 gallons per minute, being the most copious spring in England, and the water, in its short course of little more than a mile to the sea, is used to propel 11 mills.

Most deep wells have a lower origin than the zone of climate temperature, which in Britain is between 200 and 300 feet. It is well known that a regular increase in the temperature is observed after this zone is passed, equal to 1° of F. for every 55 feet. As wells have a temperature corresponding to that of the strata from which they spring, it follows that the deeper the spring the higher will be its temperature. Local conditions may affect the thermal state of springs, as in the case of the Geysers in the active volcanic district in Iceland, and the warm springs near Naples; but where no such local influences exist, the depth of the bed from which the water comes may be to some extent estimated by its temperature. Thermal springs occur in Britain at Matlock (66° F.) and Buxton (82°) in Derbyshire, at Bath (117°) in Somerset, and at Clifton (76°) in Gloucestershire. Artificial communications have been opened with deep-lying strata, by which the water they contain has been brought to the surface, and in these the temperature is found to increase in proportion to the depth of the bore. See Artesian Wells. The most remarkable thermal springs are the Geysers of Iceland, which are fully described under Geyser.

Intermittent springs are sometimes produced by the ebb and flow of the tide, as at Richmond, where the rise at high water is seen in the wells which flow from the arenaceous strata on the banks of the Thames; and sometimes they depend on the supply of rain-water. But there is a kind of spring the intermittences of which are believed to be owing to the structure of the internal cavities from which the supply is obtained. This will be more easily understood by a reference to the accompanying diagram (fig. 2). The large reservoir, A, is fed by the rain percolating through the rock. It communicates with the surface by a siphon-shaped tube, BCD. As long as the water in the reservoir is at a lower level than the arch of the siphon at C, no

Fig. 2.

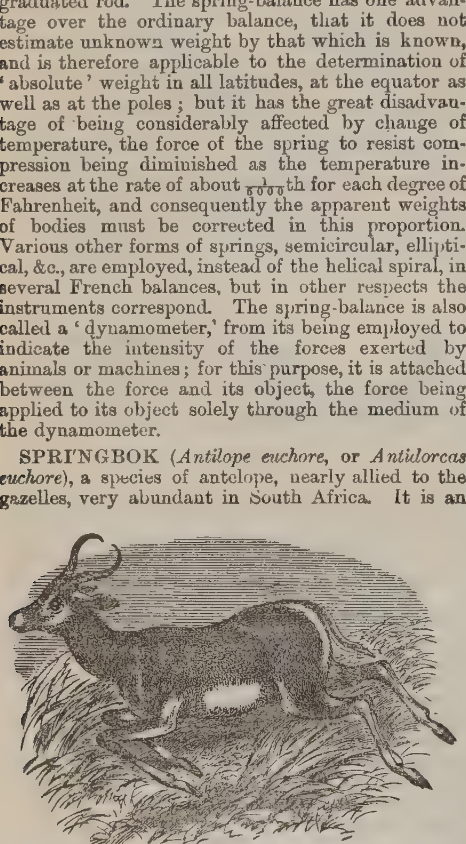
water can escape; but as soon as it reaches that level, the whole of the water in the cavity will be drawn off, the spring will then cease, and will only make its appearance when sufficient water has accumulated to permit the siphon again to act.

SPRING-BALANCE, The, for determining the weight of bodies, consists of a spring in the form of a cylindrical coil, through which passes freely a graduated bar, having a hook attached to its under end, and a plate to its upper (fig.). The spring is enclosed in an oblong or cylindrical box, quite closed except at the bottom, where there is a hole just large enough to allow the free passage up and down of the graduated bar. When the instrument is to be used, it is suspended by a ring fastened to the upper part of the box; the weight to be estimated is then hung on the hook, and pulls down the rod, the button or plate at the top of which compresses the helical spring within against the bottom of the box; and the graduation corresponding to this amount of compression of the spring, is read off at that part of the rod which just shews itself outside. In another form of the spring-balance, known as Salter's Balance, a brass index plate is attached to the side of the box, and a

Spring-balance.

vertical slit through both plate and box is made from top to bottom; the weight is in this case read off on the plate by a pointer fastened to the spring, and protruding through the slit. In a third form, known as Martin's 'index weighing-machine,' the interior rod, instead of being graduated, is furnished with a rack on one side; this rack moves a toothed-wheel fastened on the side of the instrument; and this wheel, again, has at one extremity of its axis a long index, which, on the wheel being put in motion, traverses a circular dial-plate, on which the graduations of weight are marked. The advantage of this last construction consists in the arrangement of the size of the toothed-wheel to that of the dial-plate, so that, since the toothed-wheel and index make a complete revolution simultaneously, a small motion of the former may produce a large motion of the latter, and the weight of the body be much more accurately read off than can be done directly on the graduated rod. The spring-balance has one advantage over the ordinary balance, that it does not estimate unknown weight by that which is known, and is therefore applicable to the determination of 'absolute' weight in all latitudes, at the equator as well as at the poles; but it has the great disadvantage of being considerably affected by change of temperature, the force of the spring to resist compression being diminished as the temperature increases at the rate of about $\frac{1}{5000}$th for each degree of Fahrenheit, and consequently the apparent weights of bodies must be corrected in this proportion. Various other forms of springs, semicircular, elliptical, &c., are employed, instead of the helical spiral, in several French balances, but in other respects the instruments correspond. The spring-balance is also called a 'dynamometer,' from its being employed to indicate the intensity of the forces exerted by animals or machines; for this purpose, it is attached between the force and its object, the force being applied to its object solely through the medium of the dynamometer.

SPRI'NGBOK (*Antilope euchore*, or *Antidorcas euchore*), a species of antelope, nearly allied to the gazelles, very abundant in South Africa. It is an



Springbok (*Antilope euchore*).

extremely beautiful creature, of graceful form, and fine colours. It is larger than the roebuck, and its neck and limbs much longer and more delicate. The general colour is fulvous brown on the upper parts, pure white beneath, the colours separated on the flanks by a broad band of deep vinous red. The whole head is white, except a broad brown band on each side from the eye to the mouth, and a brown spot in the centre of the face. Two curious folds of skin ascend from the root of the tail, and terminate near the middle of the back; they are usually closed, but open out when the animal is bounding, and disclose a large triangular white space which is otherwise concealed. The S. derives its name from the prodigious leaps which it takes either when alarmed or in play, often to the height of 7 feet, and sometimes of 12 or 13 feet. Its ordinary residence is in the *karroos* or arid sandy plains; but when all pasture there is burned up, immense herds congregate together, and migrate to more fertile regions, often devastating the fields of the colonist. Mr Pringle speaks of seeing the country near the Little Fish River specked with them as far as the eye could reach, and estimates the number in sight at once as not less than 25,000 or 30,000. Captain Cumming describes a still more extraordinary scene, a vast herd pouring through an opening among hills, in one living mass, half a mile in breadth, and so continuing for hours together. So dense are these herds sometimes in their migrations, that the lion or the leopard, which ordinarily hangs on their skirts with a view to prey, is taken prisoner, and compelled to march along in the midst. The strongest animals are generally foremost, but when satiated with food, they fall behind, and others, hungry and active, take their place. When taken young, the S. is easily tamed, and becomes very familiar, troublesome, and tricky.

SPRINGER. See ARCH.

SPRINGER, a kind of dog, regarded as a variety of the Spaniel (q. v.). It is small, elegant, usually white, with red spots, black nose and palate, long pendent ears, and small head. Its aspect is very lively, and its manners equally so. It is used by sportsmen for raising game in thick and thorny coverts. There are several breeds or sub-varieties.

SPRI'NGFIELD, a city of Massachusetts, U. S., on the east bank of Connecticut River, 98 miles west-by-south of Boston. It is the seat of many important manufacturing establishments, which are supplied with water-power by the falls of Mill River, and among which is the United States Armory, the most extensive in the Union, situated on an eminence called 'Armory Hill,' numerous foundries, manufactories of cotton and woollen goods, machinery, cotton-presses, steam-engines, fire-engines, locomotive-wheels, railway-carriages, India-rubber goods, &c. At the immense station-house of S. three important lines of railway meet. S. has a large city hall, 25 churches, city library and museum, a superior public-school system, including a high-school, 8 banks, and 2 daily and 3 weekly newspapers. The town, one of the finest in New England, was settled in 1635. Pop. (1860) 15,199; (1870) 26,703; (1880) 33,340.

SPRINGFIELD, the capital of Illinois, U. S., is built on a vast prairie, near the middle of the state, 188 miles south-west of Chicago, on the Chicago, Alton, and St Louis Railway. It is regularly laid out with broad streets and gardens, which have given it the name of the 'Flower City.' The State House, built in a great central square, is the principal architectural ornament. S. is also the seat of the Illinois state university, and has 13 churches, 3 newspapers, 4 banks, with foundries and flouring-mills, and is the entrepôt of a rich agricultural country. Pop. (1860) 6499; (1880) 19,743.

SPRINGFIELD, a city of Ohio, U. S., on Lagonda Creek and Mad River, 43 miles west of Columbus. It contains 10 churches, the Wittenburg Lutheran College, 1 daily and 3 weekly newspapers, 5 banks, flouring-mills, iron-foundries, woollen and paper mills, extensive railway connections, and a large trade in corn, cattle, and hogs. Pop. (1860) 7202; (1870) 12,652; (1880) 20,730.

SPRINGS, MECHANICAL, are very variously constructed for different purposes. The simplest form

of spring is a piece of elastic metal wire, rolled on a mandrel, so as to form a continuous single cylindrical coil of any length needed. Clock and watch springs are made in flat coils, thin bands of steel being used. The *balance-spring* of watches is, however, made of fine wire often thinner than hair. Coach-springs are formed of a series of curved narrow plates of steel of different sizes, placed one over the other, the largest being at the bottom, and the others in regular succession according to size, the whole being held together with nuts and screws. These are some of the commonest forms, but very many others are in use.

SPRIT (*spriet*, Dutch; old English verb, *sprit*, to sprout or spring out) means a pole or spar. The word occurs most frequently in the compound, bowsprit, which explains itself. When used alone, a sprit is a diagonal yard for sustaining a quadrilateral (usually square) fore-and-aft sail. The sprit's heel is held on the mast in a ring of rope,

Spritsail.

called a 'snotter,' and its head reaches to the after upper corner of the sail. The sail thus extended is a spritsail, and is frequently employed in boats.

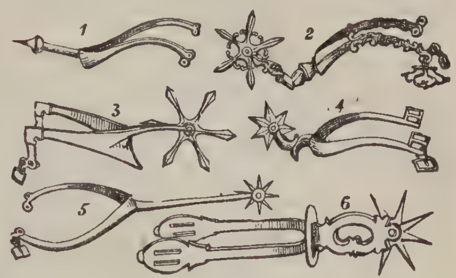
SPRUCE. See FIR.

SPRUCE, ESSENCE OF, AND SPRUCE-BEER. The essence of spruce is obtained by boiling the green tops of the Black Spruce (*Abies nigra*) in water, and then concentrating the decoction by another boiling without the spruce tops. The young shoots of this fir, like most others of its family, are coated with a resinous exudation, which is dissolved in the water. The beer is made by adding the essence of spruce to water in which sugar or treacle has been dissolved, in the proportion of about four ounces of essence of spruce to ten pounds of sugar, or three quarts of treacle, and ten or eleven gallons of water, with about half a pint of yeast. Various spices are used for flavouring. A similar beverage is made largely in the north of Europe, from the buds of the Norway Spruce (*Abies excelsa*), and is known as Black Beer, that of Danzig being the most famous. The Antiscorbutic Beer of the Russian Army Pharmacopœia is made by mixing spruce tops and fresh horse-radish root with common beer, ginger and *Calamus aromaticus* being added for flavouring, and after fermentation, a little cream of tartar, tincture of mustard, and proof spirit.

SPUI'LZIE, in the Law of Scotland, is the taking away of the movable goods in the possession of another against his will, and without any legal authority. Whenever a spuilzie has been committed, an action of damages may be brought against the wrong-doer, not only for restoration of the goods, but for all the profits which the owner might have made with the goods in the meantime. This action must be brought within three years, but the action for ordinary damages may be brought within forty years.

SPU'NGING-HOUSES are, in the Law of England, the private houses of the bailiffs, who may detain there a debtor who has been arrested for debt for twenty-four hours, to admit of his or his friends' arranging to settle the debt; and the name is derived from the extortion often practised in this state on the debtor.

SPUR, an apparatus fastened to the heel of a horseman, for goading the horse. It is much less



Various Kinds of Spurs.
(From Antiquarian Museum, Edinburgh.)

1, bronze prick spur found at Linlithgow Palace; 2, iron spur found near Bannockburn; 3, bronze spur found at Colchester; 4, brass spur found at Culloden; 5, spur found at Halidon Hill; 6, spur found in making a drain in High Street, Edinburgh.

used than formerly. All cavalry soldiers wear spurs; but their use, except in the heat of an actual charge, is discouraged as much as possible. In the days of chivalry, the use of the spur was limited to knights, and it was among the emblems of knighthood. To win his spurs, was for a young man to earn knighthood by gallant conduct. The degradation of a knight involved the hacking off of his spurs; and the serving before a knight of a pair of spurs on a dish, was a strong hint by his host that he had outstayed his welcome.

SPURGE (*Euphorbia*), a genus of plants of the natural order *Euphorbiaceæ*, having monœcious naked flowers, the male flowers membranous, and surrounding a tricoccous stalked female flower, the whole placed within a cup-shaped involucre. The fruit has three valves and three cells, the cells one-seeded, and bursting elastically. The species are very numerous, natives of warm and temperate climates, mostly herbaceous, but some of them woody. About twelve species are natives of Britain. All contain a resinous milky juice, which in most is very acrid. One of the most common British species is *E. helioscopia*, an annual plant, which has a simple stem of 4—8 inches in height, crowned by an umbel of five principal branches. The milky juice is used to destroy warts. Of the other British species, *E. peplus* and *E. exigua*, both small annuals, are among the most common, the former being generally found in gardens, the latter in fields and waste grounds. A much rarer plant in Britain is the Cypress Spurge, *E. Cyparissias*, a species with linear-lanceolate leaves, common in Germany, sometimes used as a purgative, but dangerous from its very poisonous qualities. *E. Gerardiana*, a species somewhat similar, found in many parts of Europe, is deemed a safer medicine. The CAPER SPURGE (*E. Lathyris*), a very rare plant in Britain, and probably not a true native, but common in thickets in the south of Europe, is remarkable for its violently acrid and at the same time narcotic qualities, which are especially resident in the bark of the root and the oil of the

seeds. This oil is used instead of Croton oil.—*E. officinarum* and *E. antiquorum* bear the name of EUPHORBIUM (q. v.), and yield the excessively acrid resin so called. *E. Ipecacuanha*, a North American species, growing in sandy places, yields a substitute for Ipecacuanha, but of quality less mild and less safe.

SPURGE LAUREL. See DAPHNE.

SPURN HEAD, the name given to the extreme point of a long, low, narrow, and shingly peninsula in the south-east of Yorkshire, at the mouth of the Humber, 24 miles south-east of Hull. Two light-houses have been built here, one of which is in lat. 53° 34′ 7″ N., and long. 0° 7′ 2″ E.

SPU′RREY (*Spergula*), a genus of plants which has been variously ranked by botanists in the natural orders *Caryophylleæ*, *Illecebraceæ*, and *Crassulaceæ*. The species are annuals, dichotomously branched, or with whorled branches; their leaves linear-filiform, in clustered whorls, with membranaceous stipules; the flowers in terminal divaricating corymbs. The flowers have a calyx of five sepals, five white petals, five or ten stamens, and five styles; the capsule is five-valved, with numerous round seeds, which are surrounded with a membranous wing or border. COMMON S., or YARR (*S. arvensis*), is plentiful in corn-fields, especially on light stony or sandy soils in Britain and most parts of Europe. It has weak spreading stems, sometimes two feet long in good soil, and is covered with clammy hairs. Its seeds are covered with yellowish-brown papillæ. It is commonly regarded in Britain as a mere weed; but in some parts of Europe, as Holland, Brabant, and the sandy districts of Germany, a larger variety with seeds destitute of papillæ is frequently sown for fodder. It is of very rapid growth, and is said to be as productive as an ordinary crop of clover. It is much relished by cattle. The seeds yield a bland oil, and the cake is equal in value to rape-cake.

SPURZHEIM, JOHANN GASPAR, a German physician and phrenologist, was born near Treves, December 31, 1776. While studying medicine at Vienna, he was introduced to Dr F. J. Gall (q. v.), whose pupil, and afterwards colleague, he became, in investigating the structure and functions of the brain (see PHRENOLOGY), in lecturing on the subject, and in writing for the press. In 1807 they settled in Paris, but parted in 1813; and next year S. came to England, where he published *The Physiognomical System of Drs Gall and S.* (Lond. 1815), *Outlines* of the same (1815), and a treatise on *Insanity* (1817). The first of these works having been severely handled by Dr John Gordon in No. 49 of the *Edinburgh Review*, S. proceeded to Edinburgh, and, in the lecture-room of his critic, demonstrated the reality of the anatomical discoveries which had been denied and ridiculed. To the same and other opponents, he replied in *An Examination of the Objections made in Britain against the Doctrines of Gall and S.* (Edinburgh, 1817). It was about this time, and under his tuition, that George Combe (q. v.) became a student of phrenology. After lecturing in many British and Irish cities, S. returned, in 1817, to Paris; but from 1825 till his death, he resided much in England, teaching and defending his opinions in lectures and books. In 1832, he went to America for the same purpose, and began his labours at Boston, but was cut off by fever on 10th November in that year. Besides the English works already mentioned, he wrote: *Elementary Principles of Education* (Edinburgh, 1821; 2d ed., Lond. 1828; French translation, Paris, 1822); *Phrenology* (Lond. 1825); *Philosophical Principles of Phrenology* (1825); *Phrenology in Connection with the Study of Physiognomy* (1826); *Anatomy of the Brain* (1826), supplemented, in 1829, by an Appendix, with *Remarks on Charles Bell's Animadversions on Phrenology; Outlines of Phrenology* (1827); and *Sketch of the Natural Laws of Man* (1828). Some of these were reprinted at Boston, U. S. His French works (besides those written jointly with Gall) are: *Obs. sur la Folie* (Paris, 1818); *Obs. sur la Phrénologie* (1818); *Essai Philosophique sur la Nature Morale et Intellectuelle de l'Homme* (1820); and *Manuel de Phrénologie* (1832). See *Phren. Jour.*, vol. viii. p. 126; *For. Quart. Rev.*, vol. ii. p. 15; *Memoir of S.*, by A. Carmichael (Dublin, 1833); and Combe's *System of Phrenology.*

SPY, in War, is a useful but not highly honoured auxiliary, employed to ascertain the state of an enemy's affairs, and of his intended operations. Spies have been used in all wars from the time when Moses sent Joshua on such a purpose to the present time. Their employment is quite recognised by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonour to a general to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and one devoid of honour. If taken by the enemy, he is put to death ignominiously and without mercy. As, however, the calling is so dangerous, and so little redounds to honour, it is never permissible for a general to compel by threats any person, whether of his own or the hostile party, to act as spy; but he is at liberty to accept all such services when proffered. A spy is well paid, lest he betray his employer. In the British army, spies are usually controlled by the quartermaster-general. Martial law, though distinct enough in ordering the death of a spy, is not clear in defining what constitutes a spy. A man—not of the enemy—within the enemy's lines, and in the enemy's uniform, would presumably be a spy. If in civil dress, and unable to give a good account of himself, his chance of hanging would be considerable; but if found in one camp in the uniform of the opposite side, he may not be treated otherwise than as a prisoner of war, or at least as a deserter from the enemy.

Both as regards honour and penalties, it would seem that spies ought in fairness to be divided into two classes—first, those who betray their own country to an enemy; secondly, those who, being enemies, contrive surreptitiously to obtain information by penetrating into the opposing army. The first class are traitors of a deep dye, for whom no ignominious death is too bad; but the second class are often brave men, who dare much in the service of their country. It is unfair to accord them the same treatment as the traitors.

SQUA′DRON (Ital. *squadra*, from Lat. *quadra*, a square), in military language, denotes two troops of cavalry. It is the unit by which the force of cavalry with an army is always computed. Three or four squadrons constitute a regiment. The actual strength of a squadron ranges from 120 to 200 sabres.

In naval affairs, a squadron is a section of a fleet, under command of a junior flag-officer or commodore.

SQUA′LODON, Grat. A genus typical of a peculiar family of extinct cetaceans of the miocene period. Their structure is intermediate between that of *Basilosaurus* (Zeuglodon) and more typical whales. The front teeth are subcylindric, the posterior flat, two-rooted, and serrate, the brain-case not quite so contracted as in typical whales. There are several N. American species (*S. atlanticus*, etc.), and others are European.

SQUA′LUS AND SQUA′LIDÆ. See SHARK.

SQUAMIPENNES. See CHÆTODONTIDÆ.

SQUARE, in Military Evolutions, is the forming of a body of men into a rectangular figure, with several ranks or rows of men facing on each side. With men of ordinary firmness, a square should resist the charges of the heaviest horse. The formation is not new, for a Grecian syntagma was a solid square of 16 men in every direction; but in modern warfare, the solid square having been found cumbrous, has been abandoned for the hollow square, with officers, horses, colours, &c. in the centre. The front rank kneels, and the two next stoop, which enables five ranks of men to maintain a rolling fire upon an advancing enemy, or to pour in a murderous volley at close quarters.

SQUARE, in Geometry. See PARALLELOGRAM.

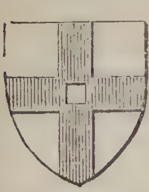
SQUARE AND SQUARE ROOT are particular cases of *Involution and Evolution* (q. v.), in which the second power and root are alone involved. The process by which the square root of a number is obtained resembles division, differing only by the circumstance, that the divisor is changed at each successive step. The rule adopted in arithmetic is deduced from algebra in the following manner: The square of $a + b$ is $a^2 + 2ab + b^2$, which may be written $a^2 + b(2a + b)$; and to find the square root of the latter, we have merely to subtract a portion (a^2), taking care that it be a square number, and forming a divisor with twice the square root of this portion ($2a$) increased by (b) the remainder of the root (which, in arithmetic, must be found by trial, as in division), and putting (b) the remainder of the root now found, in the quotient, proceed as in division. This mode of obtaining a divisor from the part of the root already obtained (a), and the part next to be obtained (b), and employing it, must be repeated till the whole square root is found. In the extraction of the square root in arithmetic, it is assumed that the squares of the nine digits are known; and also that the square of a number contains either twice, or one less than twice, as many digits as the number itself contains; the former being the case when the square number has an *even* number of digits, the latter when the number of digits is *odd*. By dividing, then, a number into periods of two figures each, we can at once see how many digits its root contains. To illustrate the method of operation adopted in arithmetic and algebra, let the square root of 128,881 be required; remembering that the square of $a + b + c$ is $a^2 + 2ab + b^2 + 2(a + b)c + c^2$:

	12,88 81(300 + 50 (or 350) + 9 = 359	
$(a^2 =)\ 300^2 =$	90000	$a + b$ (or $a + b) + c$
	38881	
$(2ab + b^2 =)\ 2 \times 300 \times 50 + 50^2 =$	32500	
$(2(a + b)c + c^2)$	6381	
$2 \times 350 \times 9 + 9^2 =$	6381	

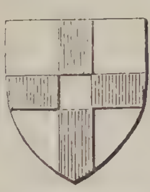
$a = 300$	12 88 81(300	$= a$
300	90000	$50 = b$
$2a + b = 650$	)38881	$9 = c$
50	32500	359
$2(a + b) + c = 709$	)6381	
	6381	

In the common arithmetical mode, the zeros are omitted, and we subtract from 12 the square nearest to it, not recognising the portion of the root, 3, as more than a digit of units, till the next period, 88, has been brought down for the second step, when it is evident that the 3 is *at least* 3 tens, and consequently the 6 in the divisor represents 60; similarly, it is only at the commencement of the third step that we find the 5 to represent 50, and the 3, 300. A comparison of the above examples will shew the agreement and difference between the two modes.

SQUARE-PIERCED, in Heraldry, a term used to designate a charge perforated with a square opening, so as to shew the field. A cross square-pierced is often improperly confounded with a cross quarter-pierced, where the intersecting part of the cross is not merely perforated, but entirely removed.



Square-pierced.



Quarter-pierced.

SQUARES, METHOD OF LEAST, in Astronomy, the best mode hitherto discovered of obtaining the most correct result from a number of observations upon any phenomenon. These observations are assumed to differ slightly from each other, and to be all of equal value, that is, taken under equally favourable conditions, and with equal instruments. The ordinary and long-established mode of approximating to the truth in such cases, is by finding the arithmetic mean, and accepting it as the correct result; but in all cases where the result required does not come directly from observation, but requires to be discovered by calculation, this simple and useful method is inapplicable, and that of 'Least Squares,' which gives more probable corrections, is adopted. The method is founded on a theorem which was first propounded by Legendre in 1806, more for the sake of insuring uniformity among calculators than from any belief in its intrinsic value; but it was afterwards thoroughly discussed and proved by Gauss and Laplace, that 'if the mean of a number of distinct observations be so taken, that the sum of the squares of its differences from the actual observations (generally designated *errors*) shall be a minimum, this mean will be, under these circumstances, the correctest obtainable value.' The process by which the mean thus obtained is shewn to be the most trustworthy approximation is too long for insertion here; but it may not be undesirable to give an example of the most common form of the method as occurring in astronomy. Let there be a series of equations—

$$\begin{aligned} X &= x + y + 2z, \\ X_1 &= 3x + 2y + 5z, \\ X_2 &= 4x + y + 4z, \\ X_3 &= -x + 3y + 3z; \end{aligned}$$

where the unknown quantities are x, y, and z, connected by various (the more the better) equations with X, X_1, &c., quantities which must be determined by actual observation. Suppose the values of the quantities thus found to be 3, 5, 21, and 14, then, since by hypothesis all these four observations are erroneous, the errors are $3 - X$. $5 - X_1$, $21 - X_2$, $14 - X_3$, or

$$\begin{aligned} 3 &- x - y - 2z, \\ 5 &- 3x - 2y - 5z, \\ 21 &- 4x - y - 4z, \\ 14 &+ x - 3y - 3z. \end{aligned}$$

The squares of these four errors are now added together; and, to find the values of x, y, and z, which will render this sum (call it S) a minimum, we must differentiate S with respect to x, y and z in turn, and putting each of these partial differential coefficients equal to zero, we obtain the three equations

$- 88 + 27x + 8y + 30z = 0$; $- 76 + 8x + 15y + 25z = 0$, and $- 157 + 30x + 25y + 54z = 0$; from which the most trustworthy values of x, y, and z can be found by common algebra.—For a full review of the whole of this subject, see a paper by Mr Ellis in the *Cambridge Transactions*, vol. viii.

SQUASH. See GOURD.

SQUIER, EPHRAIM GEORGE, American author and archæologist, was born at Bethlehem, New York, June 17, 1821. In his youth he was a school-teacher and engineer, and in 1840 was editor of *The Mechanic*, at Albany; in 1843, of the Hartford *Journal;* and in 1844, of the *Scioto Gazette*, in Ohio. His attention being attracted to the antiquities of the Scioto Valley, he made an exploration of similar monuments through the Mississippi Valley, an account of which was published in 1848, forming the first volume of the *Smithsonian Contributions to Knowledge.* He made similar explorations in New York, and on being appointed *chargé d'affaires* to Guatemala and the other states of Central America, he used his position as a means of making geographical and archæological explorations in those interesting regions. In 1851, he was honored with the medal of the French Geographical Society and Society of Arts, and made a member of other learned societies. In 1853, he surveyed a railway route through Honduras, and drew up the treaty between that country and England for the retrocession of the Bay Islands. Among his works are—*Nicaragua: its People, Scenery, Ancient Monuments, and Proposed Inter-oceanic Canal* (2 vols. 8vo, New York and London, 1862); *The Serpent Symbol, or Worship of the Reciprocal Principles of Nature in America* (1852); *Notes on Central America* (1854); *Waikna, or Adventures on the Mosquito Shore* (1855); *Question Anglo-Américaine* (1856); *The States of Central America* (1857); *Tropical Fibres* (1861); *Honduras; Descriptive, Historical, and Statistical* (London, 1870); articles in the *Encyclopædia Britannica*, &c. He was in 1864 appointed U. S. Commissioner to Peru, where he spent two years in examining the remains of the Incas, about whom he has written much, which is embodied in his book, *Peru; Incidents of Travel and Explorations* (New York, 1875).

SQUILL (*Scilla*), a genus of bulbous-rooted plants of the natural order *Liliaceæ*, nearly allied to Hyacinths, Onions, &c., and having a spreading perianth, stamens shorter than the perianth, smooth filaments, a 3-parted ovary, and a 3-cornered capsule with three many-seeded cells. Many of the species are plants of humble growth, with scapes like those of hyacinths, and beautiful flowers. Of these, two are natives of Britain: *S. verna*, which is common on the western and northern coasts, and particularly in Orkney and Shetland, and has fragrant flowers of a deep blue colour; and *S. autumnalis*, which grows chiefly on the coasts of the south of England, and has pinkish purple flowers. *S. bifolia* is a very doubtful native of Britain, but adorns hill-pastures and borders of woods in many parts of Europe with its blue flowers in early spring. *S. amœna* is another very beautiful species found in many parts of Europe. Few plants are better adapted than these for the adorning of flower-borders, or for house-culture.—Very different in habit from these is the OFFICINAL S. (*S. maritima*, or *Urginea Scilla*), a native of the sandy shores of the Mediterranean, which has a scape from two to four feet high, with a raceme of many whitish flowers, and large leaves. The bulb is of the size of a man's fist, or sometimes as large as a child's head, and contains a viscid juice so acrid as to blister the fingers if much handled, whilst the vapour arising from it irritates the nose and eyes. Squill was used in medicine by the ancients, and continues to be so still. The bulb is dug up in autumn, divided into four parts, the centre being cut out as being inert, and the remainder being cut into thin slices, which are quickly dried by a gentle heat. It is imported from Malta and other Mediterranean ports; also from St Petersburg and Copenhagen. The dried slices are white, or yellowish white, slightly translucent, scentless, disagreeably bitter, brittle, and easily pulverisable if very dry. The chemical composition of squill is not accurately known, its most active principle being a very acrid, poisonous, resinoid substance, soluble in alcohol, but not in ether. Whatever its active ingredients may be, they are taken up by alcohol, vinegar, and the dilute acids. This medicine is prescribed as a diuretic and expectorant, and occasionally as an emetic; but it must be recollected that in moderately large doses it acts as a narcotico-irritant poison, 24 grains having proved fatal. When given as a diuretic, it is usually prescribed in combination with digitalis and calomel, when it seldom fails to produce an increased secretion of urine, while at the same time it promotes the absorption of the effused fluid in the dropsy, which is generally present when diuretics are ordered. Its use is counter-indicated if inflammatory symptoms are present. Its dose as a diuretic is from one to three grains of the powdered bulb, or about twenty minims of the tincture. As an expectorant, it is much employed in the subacute stages and chronic forms of pulmonary affections, and is very serviceable in bronchitis and pneumonia of children. From its property of promoting the secretion of mucus, it gives relief by facilitating the expectoration in cases of asthma, &c., in which the sputa are viscid. In these cases, it is usually associated with some of the more stimulating expectorants, as senega or sesquicarbonate of ammonia. As an expectorant, the dose of the powdered squill should not exceed one grain, repeated several times daily. For children, the syrup, in doses of from ten to thirty minims, may be given. As its action as an emetic is uncertain, it should not be prescribed with the view of inducing vomiting, if other and more certain remedies are at hand.

Squill.

SQUI'LLA, a genus of Crustaceans, of the order *Stomapoda*, the type of a family, *Squillidæ*, to which the names *Mantis Crab*, *Mantis Shrimp*, and *Sea-mantis*, are popularly given, from the strong general resemblance to the insects of the genus *Mantis* (q. v.). The form is elongated; the carapace only covers the anterior part of the thorax, the latter part of which is formed of rings like the abdomen; the eyes are carried on stalks; the claws are very large, and furnished with spines, forming powerful instruments of prehension; the tail is

expanded into a broad fin. The species are numerous, and mostly inhabit tropical seas. A species about seven inches long, *S. mantis*, is found in the Mediterranean. The *Squillæ* are extremely active, and very bold and voracious.

SQUINCH, small arches or corbelled courses across the angles of square towers, to bring in the form to carry an octagonal spire, lantern, &c. See PENDENTIVE.

SQUI'NTING, or **STRABI'SMUS**, is a well-known and common deformity, which may be defined as a want of parallelism in the visual axes, when the patient endeavours to direct both eyes to an object at the same time. The squint is said to be *convergent* when the eye or eyes are directed towards the nose, and *divergent* when they are directed towards the temple, and is termed *single* or *double* according as only one eye or both are displaced. The divergent form is comparatively rare, except in consequence of a prolonged loss of sight of one eye. The causes of this affection are various. Intestinal irritation, such as the presence of worms, will often induce it slightly in children. In other cases, it may be traced to the temporary cerebral irritation produced by teething; and it is a very common symptom in hydrocephalus and other serious head-affections. Amongst other causes are a want of equal normal visual power in both eyes, in extreme short-sight; but from extensive observation with the ophthalmoscope, Mr Dixon, surgeon to the Royal Ophthalmic Hospital, Moorfields, has come to the conclusion, that 'in the great majority of instances of confirmed squint existing in children, the optic nerves themselves are ill-developed, being usually smaller than natural, of a more or less oval form, and of a dusky colour.'—Holmes's *System of Surgery*, vol. ii. p. 890. If the squint is only temporary, and possibly arises from intestinal irritation, the bowels must be well cleared out, and tonics subsequently given. If it is due to some peculiarity in the visual focus of the eyes, it may be removed by the judicious use of glasses. 'In every case,' says Mr Dixon, 'a careful ophthalmoscopic examination is the first duty of the surgeon; and he should also take every possible care to ascertain that no organic disease exists in the brain or orbital nerves; and that there is no tumour in the orbit, mechanically burdening the movements of the eye.' The surgical operation for the cure of squint consists in the division of the muscle which, by permanently drawing the eye inwards or outwards, and overpowering its antagonistic muscle, induces the deformity. It is better to dispense with the use of chloroform in this operation, if the patient have sufficient nerve to bear the operation without flinching, as in that case the doubt that sometimes arises as to whether the muscle has been sufficiently divided can be at once solved by directing the patient to attempt inversion of the eye; but in the great majority of cases, chloroform is found necessary.

SQUINTS, narrow apertures cut in the walls of churches (generally about two feet wide), to enable persons standing in the aisles to see the high altars. These openings are always in the direction of an altar.

SQUIRE, an abbreviated term for Esquire (q. v.). The same word is also popularly applied in England to country gentlemen; and in the United States of America to magistrates and lawyers, and sometimes to judges and justices of the peace.

SQUIRREL (*Sciurus*), a Linnæan genus of rodent quadrupeds, now the family *Sciuridæ*. They belong to the section of *Rodentia* having perfect clavicles, and are further characterised by a long bushy tail; the fore-paws furnished with four toes, which have curved claws, and a tubercular thumb; the hind-legs long, their feet with five toes; two incisors in each jaw; four molar teeth on each side in each jaw, simple, with tuberculous crowns, and a fifth in the front of the upper jaw, which soon falls out. Most of the species commonly carry the tail curved over the body, whence the Greek name *Skiouros* (*skia*, a shade, and *oura*, a tail), of which the English *squirrel* is a corruption. The species are numerous, and are found in almost all parts of the world, except Australia; some inhabiting temperate and even cold regions, whilst some belong to tropical countries. Squirrels are very active and lively creatures, at once shy and pert, very adroit in hiding themselves on the appearance of danger, but resembling monkeys in their inquisitive curiosity. They inhabit woods, and mostly spend their lives in trees, which they climb with wonderful agility, running along the branches, and leaping from tree to tree. Their running is a kind of bounding, and the tail is then stretched out, as it is also in their leaps from branch to branch, which are often to great distances. The Flying Squirrels are already noticed. Even the true squirrels resemble them in spreading out their limbs and tail to the utmost in leaping, particularly when they descend from a high branch to the ground, and they thus leap from a great height without injury. Some species, however, seldom ascend trees, but burrow in the ground, and are further distinguished by having cheek-pouches, whilst the tail is shorter than in the tree squirrels, and its hair not so distinctly arranged in two lateral rows. These *Ground Squirrels* form the genus *Tamias*. All the squirrels feed on fruits and seeds, the young shoots of trees, and other such vegetable substances; although they sometimes vary their diet by plundering birds' nests, and not only sucking eggs, but devouring young birds. They are also fond of the larvæ of insects. In eating, they often sit erect, and hold the food in their fore-paws. The hardest nut presents no difficulty to their sharp strong teeth. Many of the species, and probably all those of temperate and cold climates, lay up stores for winter.—The COMMON S. (*S. vulgaris*) of Europe is a beautiful little animal

Common Squirrel.

about eight inches and a half in length without the tail, which is fully six inches long, besides being apparently lengthened by its long hair. It is brownish red on the upper parts, and white beneath; the colour changes more or less in winter to a grayish brown, and in northern countries to gray, and even to white. The long hairs which fringe the ears, and are drawn up into a fine point, are longer in winter than in summer. The Common S. is

widely distributed over the northern parts of the Old World, and is plentiful in England, and in some of the southern parts of Scotland, into which, however, it is said to have been introduced. It is generally protected and its presence desired in the vicinity of mansions; although it often does considerable injury in plantations by gnawing off the top-shoots of trees, particularly of firs and pines. Morning is generally the time of the squirrel's greatest activity, except in winter, when it prefers the warmest hours. Although numbers are often seen together, they live mostly in pairs, which seem to continue attached throughout life. The S. makes a beautiful nest of moss, twigs, and dry leaves, curiously interwoven, most frequently in the fork of a tree at a considerable height from the ground. Here the young are produced, three, four, or five at a birth, in the middle of summer. They continue with their parents till the spring of next year. The winter hoards of the S., containing nuts, beech-mast, grain, and the like, are usually in holes in the ground about the roots of trees, not far from its ordinary abode, the same pair of squirrels having often a number of these hoards. The seeds of firs form a very considerable part of the winter-food of squirrels, and to obtain them, the scales are gnawed away from the cones. The S. is easily tamed, and is an amusing pet. It is almost in constant motion, except when asleep.—The only other European species is the ALPINE S. (*S. alpinus*), a native of the Alps and Pyrenees, about the same size with the Common S., deep brown, speckled with yellowish white.—North America abounds in species of squirrels. The GRAY S. (*S. migratorius*) occurs in the northern parts of the United States, and as far north as Hudson's Bay. It is much larger than the European S., the whole length with the tail being nearly two feet. It is usually light gray, with yellowish-brown head, and longitudinal stripes of yellowish brown, but it is often found almost entirely black. Its habits are very similar to those of the Common S., but it is more gregarious. Gray squirrels sometimes visit corn-fields in large numbers, and make great devastation. In Pennsylvania, an old law gave a reward of threepence a head for every S. destroyed, and in the year 1749 no smaller a sum than £8000 was paid out of the treasury on this account, so that 640,000 squirrels must have been killed. Hosts of this species of S. sometimes leave their native woods, and migrate like the Lemming (q. v.) of Northern Europe, whether urged by scarcity of food or through some other unknown impulse. These migrations usually occur in autumn, and are regarded with great horror by farmers. The squirrels advance in a straight course; mountains are no impediment, and although they swim with difficulty, they cross large rivers and the narrow bays of lakes.—The CAROLINA GRAY S. (*S. Carolinensis*) is a rather smaller species, abundant in the south-eastern parts of the United States, where its flesh is highly esteemed. A number of other species are found in different parts of North America, and very beautiful species occur in tropical countries, some of which live mostly in palms.—Of Ground Squirrels, several species are natives of North America, of which the best known is the CHIPPING S., HACKEE, or CHIPMUCK (*Tamias Lysteri*), abundant in almost all the eastern part of the United States, and as far as 50° N. lat. Its length, with the tail, is fully ten inches; the general colour gray, longitudinally striped with black and yellowish white. It derives its name from its *chipping* or chattering cry, which is like that of a young chicken. It seldom ascends trees; and is not troublesome to the farmer, as it does not attack standing corn, but gleans the fields, and feeds on fallen nuts in the woods. It burrows near the roots of trees, and several squirrels generally inhabit one burrow, which is deep and winding, and in which stores are laid up for winter use. In carrying nuts or other food to its retreat, it makes use of its cheek-pouches, cramming and distending them to the utmost.—A very similar species (*T. striatus*) inhabits Siberia.

The fur of some of the American squirrels is an article of commerce. It is one of the cheapest kinds of fur.

SQUITCH. See COUCH GRASS.

S'RÂDDHA (from the Sanscrit *s'raddhâ*, faith, belief) is the name of the funeral ceremony of the Hindus, in which balls of food, and water, are offered to the deceased ancestors of the sacrificer, or to the *Pitr'is* or manes collectively. It is especially performed for a parent recently deceased, or for three paternal ancestors, and is supposed necessary to secure the ascent and residence of the souls of the deceased in a world appropriated to the manes. But this ceremony is observed also on occasions of rejoicing as well as of mourning; and hence various S'râddhas are enumerated—viz. 1. S'râddhas which are *constant*, or the daily offerings to the manes in general, and those offered on the eighth lunation of every month; 2. S'râddhas which are *occasional*, as those for a relative recently deceased, or those to be performed on various domestic occurrences, as the birth of a son, &c.; and 3. S'râddhas which are *voluntary*, performed for a special object, such as the hope of religious merit, &c. The proper seasons for the worship of the manes collectively are the dark fortnight or period of the moon's wane, the day of new moon, the summer and winter solstices, eclipses, &c. The presentation of the ball of food to the deceased, and to his progenitors in both lines, is the office of the nearest male relative, *and is the test and title of his claim to the inheritance.*—See for further detail, H. H. Wilson's *Glossary of Judicial and Revenue Terms* (Lond. 1855), under *S'râddha*.

S'RÂVAKA (from the Sanscrit *s'ru*, to hear) is the name of the disciples of Buddha, who, through the 'hearing' of his doctrine, and by practising the four great Buddhistic truths, attain to the qualification of an Arhat, or Buddhist saint. From among the number of the disciples of Buddha, 80 are called the *Mahâs'râvakas*, or the great S'râvakas. The S'râvakas are entitled to the predicate *Âyushmat*, or 'one possessed of (long) life.'

S'RUTI (from the Sanscrit *s'ru*, hear, hence, literally, the hearing, or that which is heard) is, in Sanscrit Literature, the technical term for all those works which are considered to have been revealed by a deity. It applies, therefore, properly speaking, only to the Mantra and Brâhmana portion of the Vedas; but at a later period, it is applied likewise, if not especially, to the Upánishads. See VEDA.

SS, COLLAR OF, a collar composed of a series of the letter S in gold, either linked together or set in close order, on a blue and white ribbon, with the ends connected by two buckles and a trefoil-shaped link, from which hangs a jewel. Such collars have been much worn in England by persons holding great offices in the state, as well as by the gentry of various ranks, from esquires upwards. They are of frequent occurrence on sculptured monuments; but the origin of the device has not been satisfactorily explained. Among the numerous conjectures which have been formed regarding its meaning, one is, that the letter S stands for 'souveraigne,' the favourite motto of Henry IV.; others have suggested 'seneschal;'

and M. Planché hints that it may, with equal probability, owe its origin to the swan of the De Bohuns, that badge being found in one of the earliest examples of this collar (1402), pendent round the neck of the poet Gower, in St Saviour's Church, Southwark. The collar had, without doubt, originally a Lancastrian character. Collars of SS are still worn, with certain recognised distinctions, by the Lords Chief Justices, the Lord Chief Baron of the Exchequer, the Lord Mayor of London, the Heralds and the Serjeants-at-Arms.

STA'BAT MA'TER, a celebrated Latin hymn on the Crucifixion, beginning

> Stabat mater dolorosa
> Juxta crucem lacrimosa
> Dum pendebat filius.

The *Stabat Mater* forms part of the service of the Roman Catholic Church during Passion-week. Its authorship has been assigned to Jacopone, a Franciscan, who flourished in the 13th century. It has been set to music by many composers of eminence. Pergolese's *Stabat Mater*, written by that eminent musician on his deathbed, is justly celebrated for its pathos and expression. Rossini's more secular *Stabat Mater* is also well known to all lovers of music.

STABI'LITY AND INSTABI'LITY. When a body rests upon a surface, in such a manner that a vertical from its centre of gravity falls within the largest polygon which can be formed by joining the various points of contact of base and surface, it will stand; but if the contrary is the case, it will fall, unless extraneously supported. If the base of the body be a plane, and the supporting surface convex, or *vice versâ*, or if both base and surface be convex, there will be only one point of support, and if the body be at rest, its centre of gravity must be vertically over the point of contact. Should a body so placed receive a slight impulse, it will either oscillate to and fro, ultimately returning to its original position, or remove further and further from its original position, shewing a tendency not to return, or appear indifferent to any one position. In the first case, the body is said to be in *stable*, in the second case, in *unstable*, and in the third, in *neutral* equilibrium. Fig. 1

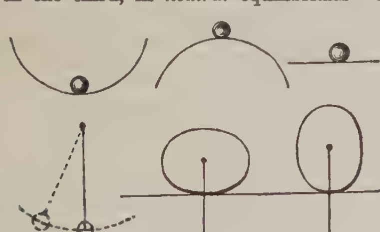


Fig. 1.

shews various illustrations of these three species. It will appear at once that the predetermining cause of equilibrium being of one rather than of another of these species, is the tendency of the centre of gravity of every body to seek a lower position; and the illustrations shew that in stable equilibrium the centre of gravity of the body may, and in unstable equilibrium may not, attain a lower position, while in neutral equilibrium its position continues unaltered. In illustration of the mode in which the species of equilibrium possessed by a body which has received a slight impulse is determined, let us take the case of a body with a spherical base resting upon a spherical surface (fig. 2); let S and O be the centres of the spherical surfaces respectively, and let A be their point of contact (the centre of gravity being consequently in the line SA, or in it produced towards S, and after displacement, in the line S′A′, produced if necessary), let the new position of S, after the body

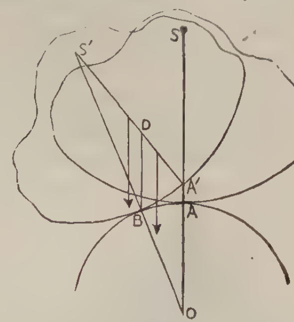

Fig. 2.

has been slightly displaced, be S′, and the new point of contact B; join OS, OS′, S′A′, and draw BD vertically, that is, parallel to OC. Then $A'D : A'S' :: OB : OS'$, or $A'D = \frac{A'S' \times OB}{OS'}$, that is, $A'D$ = the product of the radii of the two surfaces divided by their sum. Now, should the centre of gravity of the displaced body fall between D and A′, it will have a moment round B tending to restore the body to its former position (*stable equilibrium*); should the centre of gravity be beyond D from A′, its moment round B will tend to increase the displacement (*unstable equilibrium*); while, if it fall in the line BD, it will still be above the point of contact, as it was at first, and there will be no tendency either to return to, or to move further from, the original position (*neutral equilibrium*). These conditions may be briefly expressed by the following formulæ, in which R is the radius of the supporting surface, r of the spherical base of the body, and X the distance of the centre of gravity from the point A; when equilibrium is stable, X is less than $\frac{R \times r}{R + r}$; when unstable, X is greater than $\frac{R \times r}{R + r}$; and when neutral, $X = \frac{R \times r}{R + r}$. From these formulæ, the conditions of equilibrium of a body, with a spherical base on a plane surface, can be at once deduced by making $R = \infty$, the three species of equilibrium being then represented in order by X less than r, X greater than r, and $X = r$; the simplest illustrations of these being respectively a segment of a sphere, a tall cone on a spherical base, and a sphere.

STACCA'TO (Ital. detached), in Music, a term implying a detached, abrupt mode of performance. A certain amount of time is subtracted from the proper value of any note played staccato, and a rest substituted. A dot placed over a note indicates that it is to be played staccato: . A dash implies a greater degree of staccato: , and a very slight degree of staccato is expressed by uniting the dot with the slur: ; the slur being the sign of a *legato* expression, the converse of staccato.

STA'CHYS, a genus of plants of the natural order *Labiatæ*, containing a great number of species, mostly European, having a ten-ribbed calyx, with five nearly equal teeth, the upper lip of the corolla entire, and the lower lip three-lobed. Several species are natives of Britain. *S. sylvatica* is very common in shady places, a coarse herbaceous plant, sometimes called *Hedge Nettle*, with stem 2—3 feet high, ovate heart-shaped leaves on long stalks, whorls of purple flowers, and unpleasant smell. *S. palustris* is another very common British species, growing in moist places, and sometimes proving a

Betony (*Stachys officinalis*).

very troublesome weed in meadows. The plant was formerly used as a vulnerary, and has therefore the English name *Woundwort.* Several species are not unfrequently to be seen in flower-gardens. To this genus some botanists refer the COMMON BETONY or WOOD BETONY (*S. betonica*, or *Betonica officinalis*), plentiful in woods and thickets in the southern parts of Britain, a plant one or two feet high, with hairy stem, oblong heart-shaped leaves, whorls of purple or white flowers, and a fetid smell. It was formerly much used in medicine. The roots, in small doses, are emetic and aperient.

STADE, a small but very ancient fortified town of Prussia, province of Hanover, about a mile from the mouth of the Schwinge in the Elbe. Pop. 8544.

The *Stade Dues* were a toll or duty which was formerly charged by the Hanoverian government on all merchandise carried up the Elbe to Hamburg. The original duties, as regulated by a treaty of date 1691, were comparatively light, but they had been gradually increased till they brought to Hanover a revenue of £40,000. After several modifications in 1844 and 1854, this vexatious toll was finally abolished in 1861, Hanover receiving a compensation equivalent to £30,000 annually, of which Great Britain paid one-third, another third was contributed by Hamburg, and the remaining third divided proportionally among the other countries that traded to the Elbe.

STA'DIUM, the course set apart for foot-races and all the other games excepting horse-racing, which were wont to be celebrated at Olympia and other places in Greece; the horse and chariot races being held in the *Hippodrome* (q. v.). The stadium was of the same form as the hippodrome, and the arrangement of the spectators was similar. The distance between the starting-point and the goal was, in the Olympic stadium, about 600 Greek feet, and the stadia of other places adopted the dimensions of that at Olympia. This distance of 600 Greek feet was adopted as the chief Greek measure of length, and called a *stadium.* It was equivalent to 625 Roman feet, or 125 Roman paces; hence the Roman mile of 1000 paces contained exactly 8 stadia.

STA'DTHOLDER (Ger. *stadthalter*, Dutch *stadhouder*, lieutenant or governor of a province). In the German cantons of Switzerland, the name is given to the second civil officer, who ranks next to the landamman. In the republic of the Seven United Provinces, the chief magistrate or president of the union was called the stadhouder. In the 16th c., when the tyranny of Ferdinand, Duke of Alva, governor under Philip II., drove the principal towns into revolt, they chose William, Prince of Orange, for their governor, and with the view of letting it be understood that the revolt was not against Philip, but against Alva, they conferred on William no higher title than that of Stadhouder. On the assassination of William in 1584, the provinces of Holland, Zeeland, and Utrecht agreeing to have one stadhouder, appointed Maurice of Nassau to that office, which came tacitly to be looked on as hereditary. The stadhouderate thus instituted was considered to be at an end or in abeyance on the extinction of the line of William I., by the death of William III. However, on the triumph of the Orange party over the Republican in 1747, William IV., descended from a collateral branch of the House of Nassau, was proclaimed stadhouder, captain-general, and admiral-in-chief of the Seven United Provinces, those dignities being made hereditary in his family. His son, William V., the seventh stadhouder, was driven from his country by the French in 1795, and resigned his office in 1802; since which time, the stadhouderate has never been revived, the Netherlands having, at the Congress of Vienna, been formed into a kingdom.

STAËL-HOLSTEIN, ANNE LOUISE GERMAINE NECKER, BARONNE DE, was born at Paris, April 22, 1766. Her father was the celebrated M. Necker (q. v.), finance minister of Louis XVI., in the times immediately preceding the Revolution. Her mother was a woman of severe character, and from her earliest years subjected her to a discipline almost puritanic in its rigour. The daughter, in consequence, had no very warm attachment for her; but for M. Necker, who softened as he could by his indulgent tenderness the harsh rule of his spouse, she entertained the most ardent affection, regarding him then and always with what was almost an idolatry of fondness and admiration. Her talents were precociously developed, and whilst yet the merest girl, she would listen with eager and intelligent interest to the conversation of the Parisian *savans* who used to frequent the house of her father. In 1786, she was married to the Baron de Staël-Holstein, Swedish minister at Paris, an elderly gentleman, with whom her happiness was probably not great, inasmuch as, a few years after, a separation between them took place, two sons and a daughter having been meantime the fruit of their union. In 1788, she issued her first work, *Lettres sur les Ecrits et le Caractère de J. J. Rousseau*, which are rather a passionate eulogy of a girlish idol than a just and discriminating criticism.

Her sympathy with the Revolution in its earlier stage of promise was profound, but gave place, as its later enormities were developed, to a reaction of horror, which is vividly set forth in her subsequent *Considérations sur la Révolution Française.* Her grief was extreme on the failure of the attempt to

escape on the part of the royal family, and she engaged in a secret scheme for securing them a flight to England. This, however, came to nothing; and she then, along with her father, betook herself to Switzerland, his native country. The news of the king's execution inexpressibly shocked her; and she sought to save the life of the queen by publishing *Réflexions sur le Procès de la Reine, par Une Femme*, which, however, was too late to be effective. In 1795, she published at Lausanne, under the title *Recueil de Morceaux Détachés*, a collection of her juvenile writings; and the year after, a treatise *De l'Influence des Passions sur le Bonheur des Individus et des Nations*, a work full of originality and genius. In 1797, order having been re-established under the Directory, she was once more in Paris. From the first, she distrusted the designs of Napoleon, and her *salon* became the headquarters of the anti-Bonapartist faction. In vain she was offered restitution of two million livres since 1788 due to her father from the royal treasury; she scornfully declined the bribe; and as neither fear nor favour could lead her to disguise her hostility to him, it seemed well for Napoleon to rid himself of her. She was forbidden to live in Paris, and subsequently (1802) exiled from France itself. Meanwhile, she had greatly increased her reputation by the publication of her romance of *Delphine*, and a work *Sur la Littérature considérée dans ses Rapports avec l'Etat Moral et Politique des Nations*. She now, for two years, travelled in Italy and in Germany, making at Weimar the acquaintance of Goethe, Schiller, Herder, Wieland, &c. The death of her father in 1804 recalled her to Coppet, in Switzerland. Subsequently, she was permitted to return to Paris, and there, in 1807, she published her famous *Corinne, ou l'Italie*, the success of which was instant and immense, and won for her a really European reputation. As a bitter in the sweet of fame, however, fresh difficulties with Napoleon occurred, and she was banished anew to Coppet. Her son, the Baron Auguste, then 17 years old, sought to intercede for his mother in a personal interview granted him by the emperor, whose inexorable deliverance on the occasion is too characteristic and amusing to be omitted: 'Avec l'exaltation de sa tête, la manie qu'elle a d'écrire *sur tout et à propos de rien*, elle pouvait se faire des prosélytes; j'ai dû y veiller.' And in candour it is to be admitted, despite of the shrieks which have ever since been put forth about Napoleon's so-called 'ungenerous persecution,' that he acted on the dictate of a sound prudential policy. A woman who would keep no terms with him, who was uncompromising and fearless, and an influence by the weight of her genius and reputation, was clearly in Paris, of all places, a phenomenon not to be tolerated by the head of a government such as his, more or less the sport of the hour, as always in its basis precarious. After this, when disgusted with Coppet, where she found herself subjected to a petty *surveillance*, Madame de S. rushed restlessly over Europe to Vienna, Moscow, St Petersburg, thence through Finland to Stockholm, and afterwards to London, where, in 1813, she published her great book, *De l'Allemagne*, which had previously been suppressed in Paris. As the first decisive revelation of the genius of Germany to the French people—somewhat as the earlier writings of Mr Carlyle revealed it to the reading public of Britain—this may perhaps rank as the most important and influential of her works. Of her various experiences of travel, an interesting record is preserved in her *Dix Années d'Exil*. At the Restoration, she returned to her beloved Paris; from Louis XVIII. she met with a most gracious reception; and restitution was granted her of the two millions on her father's account before mentioned. Soon after, her health failed; she sought its restoration in a visit to Italy in 1816, but without effect, and on July 14, 1817, she died at Paris. She was buried at Coppet; and by her will the fact was revealed that, in 1812, she had privately married M. de Rocca, a French officer of hussars, aged 25; which may be looked upon as something of an *escapade* for a mature matron of 46. In this wedlock, she gave birth to a son. M. de Rocca survived her only a few months. On the whole, she had scantly been happy, as cursed with the 'desires infinite and hopes impossible' which make life little better than a sad unfulfilled longing to many of her peculiar temperament and genius. Her touching wail of '*Jamais, jamais, je ne serai jamais aimé comme j'aime*' was a cry out of her inmost heart. In this light, there may perhaps seem some element of pathos in this marriage, which looks otherwise a little ridiculous.

Madame de S.—all just deduction from her claims being made—must be ranked in the first class of female genius. Without question of her real power and originality, in the combination she presents of such a force of intellect as women have but rarely exhibited, with depth and tenderness of sentiment seeking its natural outlet in a rich and impassioned rhetoric, she may curtly, yet with clearness sufficient, be defined as a sort of Rousseau in petticoats.

STAFF, in Music, the name given to the five parallel lines and four intermediate spaces on which the characters indicating musical sounds are placed, the various degrees of the staff indicating differences of pitch .

STAFF, in a Military sense, consists of a body of skilled officers, whose duty it is to combine and give vitality to the movements and mechanical action of the several regiments and drilled bodies composing the force. The distinction between an officer on the staff of an army and a regimental officer is that the latter is concerned with his own regiment alone, while the former deals with his army, or section of an army exceeding a regiment, and regulates the combined action of the several arms and bodies of men. A good staff is all-important to the success of a military enterprise.

The *General Staff* of an army comprises the general in actual command, with the subordinate generals commanding the several divisions and brigades: as assistants to these, the officers of the adjutant-general's department—i. e., the adjutant-general, his deputy, assistants, and deputy-assistants, if the army be large enough to require all. Similarly, the officers of the quartermaster-general's department; the brigade-major; the provost-marshal; and the judge-advocate; the functions of all of whom are described under their respective heads. The general staff of the British army consists at present of a field-marshal commanding-in-chief, whose head quarters are at London; under him, of a lieutenant general commanding-in-chief in Ireland. This command includes, of course, the general officer commanding in each military district of the United Kingdom and in each colony; each of these generals having the usual subordinate staff subject to his orders. India forms a nearly independent command, under a commander-in-chief, whose headquarters are in Bengal. There are subordinate commanders-in-chief in Bombay and Madras; and in each presidency there are several military divisions. A certain period of military service, and certain qualifications, are required in an officer before he can be appointed to the general staff, and the

preference is given to officers who have passed the Staff-College.

The *Personal Staff* consists of the aides-de-camp and military secretaries to the respective general officers. These officers, who are treated of separately, are appointed, within certain limits, by the generals whom they serve, and their appointments expire on those generals ceasing to command.

The *Garrison Staff* consists of the officers governing in fortresses and garrisons; as Commandants (q. v.), Fort-majors (q.v.), Town-majors (q. v.), Fort-adjutants (q. v.), and Garrison-adjutants.

The *Civil or Departmental Staff* includes those non-combatant officers who have to provide for the daily requirements of the troops. These are the commissariat, barrack, medical, chaplains, purveyors, store and veterinary departments. These departments are described under their several names.

The *Recruiting Staff* consists of inspecting field-officers, district paymasters, district adjutants, and superintending officers. See RECRUITING.

The *Pensioner Staff* includes only the staff-officers of the enrolled force. See PENSIONERS.

The *Volunteer Staff* has an inspector-general, with his deputy, and assistant-inspectors in the several volunteer districts. See VOLUNTEERS.

The *Regimental Staff* includes the colonel, lieutenant-colonel, major, adjutant, paymaster, quartermaster, inspector of musketry, and medical officers. See REGIMENT.

In the French and most of the continental armies, the staff is divided into the *état-majeur*, or general staff, and the *intendance*, under an *intendant-général*, which comprises all the civil departments. There is, of course, a regimental staff in addition. The want of this concentration of the civil departments has been often felt in the British service. See INTENDANT.

In the Navy, the staff of a fleet consists of the Flag-officers (q. v.), the Flag-lieutenants (q. v.), and Secretaries (q. v.); also of the inspector-general of hospitals (see MEDICAL DEPARTMENT, NAVY), and an inspector of machinery.

STA'FFA, a celebrated islet on the west of Scotland, lies about 7 miles off the west coast of Mull. It forms an uneven tableland, rising at its highest to 144 feet above the water, 1½ miles in circumference, and oval in shape. In the north-east, in the lee of the prevailing winds, is a tract of low shore, stretching out in beaches, and forming a landing-place. The other parts of the coast are girt with cliffs of from 84 to 112 feet high. Regarded in section, the rocks shew themselves to be of three kinds—conglomerated tufa forming the basement; columnar basalt, arranged in colonnades, which form the façades and the walls of the chief caves; and amorphous basalt, overlying the columnar basalt, but pierced here and there by the ends of columns and by angular blocks. The most remarkable feature of the island is Fingal's or the Great Cave, the entrance to which is formed by columnar ranges on each side, supporting a lofty arch. The entrance is 33 feet wide, and 60 feet high, and the length of the cave is 212 feet. The floor of this marvellous chamber is the sea, which throws up flashing and many-coloured lights against the pendent columns, whitened with calcareous stalagmite, which form the roof, and against the pillared walls of the cave.

STAFF COLLEGE is a British institution founded in 1858, about two miles from Sandhurst, to the Military College at which place it is affiliated, for the purpose of giving higher instruction to 30 officers aspiring to appointments on the staff. It thus took the place, though more effectively, of the old senior class at the Royal Military College. To be entitled to compete for entrance, an officer must have been three years in active service, must have passed the qualifying examination for a captaincy, and must have the recommendation of his commanding officer. A very serious examination decides which among the competitors shall be admitted to the college, one only being eligible from any battalion. While at college, the students receive their regimental pay, and the whole educational charges (annually £8670) are borne by the public. The course lasts two years. At the end of each year, there is an examination; that of the second fixing the order of the candidates' choice for staff employment. After passing the Staff College, the officer is attached for duty, for a short period, to each of the arms with which he may not have already served. He then becomes eligible for appointment to the staff as opportunity may occur.

STAFF CORPS. During the wars of Wellington, the generals and staff officers were aided by a staff corps composed of intelligent officers and men who performed camp duties, made reconnaissances, and executed other necessary labours for which regimental officers or soldiers were unsuited. This corps died out after the peace. At present, there are three staff corps—the Commissariat Staff Corps, Army Hospital Corps, and Military Store Staff Corps—which consist of artificers, labourers, and orderlies, to aid in the work of their respective departments—as butchers, wardmasters, armourers, copyists, &c. The annual cost of these three corps is about £65,000.

STA'FFORD, an inland county of England, bounded on the W. and N.-W. by Shropshire and Cheshire, has an area of 728,468 acres, and a pop of (1881) 981,385. The most elevated portion of the county is the north, where wild moorlands in long ridges, separated by deeply cut valleys, extend from north-west to south-east, and subside as they near the valley of the Trent. The surface is low or undulating in the midland regions, but becomes hilly again in the south. New red sandstone occupies the whole of the central parts; the Pottery coal-field occupies the north, and the Dudley coal-field, remarkable also for its abundant and rich iron ores, occupies the south. The Trent, flowing first south-west through the county, then north-east along its eastern border, is the chief river. The climate is cold and humid, and though three-fourths of the area are arable, much of the soil is cold and clayey, and agriculture is in a backward condition. The Potteries lie around Stoke (q. v), Burslem, and Hanley, and here most extensive manufactures of china and earthenware are carried on. See POTTERY and WEDGWOOD. In the south, iron is very largely manufactured in all its branches, from mining to the production of articles in iron and steel. The numerous canals (including the Grand Trunk Canal) and railways which intersect and traverse the county, afford abundant and most useful means of communication and conveyance. The county of S. returns six members to the House of Commons.

STAFFORD, the county town of Staffordshire, stands on the Sow, 25 miles north-north-west of Birmingham. The usual municipal institutions of county towns are the chief buildings, and there are two fine and partly ancient parochial churches Tanning, cutlery, and the manufacture of shoes are the chief branches of industry. S. sends two members to the House of Commons. Pop. (1881) 19,901.

STAG, a name familiarly given to a person who applies for an allocation of shares in a joint-stock concern with a view of selling the allocation letter to another party for a small consideration.

When no such consideration or premium is obtainable, the *stag* does not pay the deposit, which by his application he had become bound to do, and relinquishes any further interest in the undertaking. Persons acting thus, however, are liable to prosecution and exposure as defaulters. During the great railway mania of 1846, the stock-market was thronged with stags.

STAG, or RED DEER (*Cervus elephas*), a species of Deer (q. v.) with round antlers, which have a snag at the base in front. The female has no horns, and is called a *Hind*. The young male, during the first year, acquires mere knobs in place of horns. In the second year they are longer and pointed, when the animal is called a *Brocket*. The branching of the horns increases every year till the sixth, when the name Hart (q. v.) begins to be applied. After this, the age is no longer indicated by an increased number of branches, but the antlers become larger and thicker, their furrows deeper, and the *burr* at the base more projecting. The oldest stags have seldom more than ten or twelve branches, although an instance has occurred of 33 on each antler. A fine S. is four feet or more in height at the shoulder. The colour is reddish brown in summer, the rump pale; in winter, it is brownish gray. The female is smaller than the male. The young is at first spotted with white. The S. is a native of Europe and the north of Asia. It was anciently common in all parts of Britain, but is now almost extinct, except in the Highlands of Scotland, where large herds still exist, particularly on the Grampians, and the sport of deer-stalking is pursued, in which the rifle is now generally used; although, in former

Stag, Hind, and Calf (*Cervus elephas*).

times, the S. was hunted, hounds of a peculiar breed, called Staghounds (q. v.), being employed for the purpose. The forest laws of England were extremely strict for the preservation of this noble game, the unauthorised killing of a S. being even a more unpardonable offence than the killing of a man. The S. feeds on the buds and young shoots of trees, and on grass; or, in the severe weather of winter, on bark and mosses. The speed of the S. is very great. It has also great powers of swimming, and has been known to swim ten miles. When hard pressed by hunters, it turns to bay, and is not approached without danger. At the pairing season, which is in August, even tame stags become so excited that it is not safe to approach them. The domestication of the S. is never very complete. In fighting, the S. uses not only its horns, but its fore feet, with which it gives severe blows to an adversary. The flesh of the S. is not so good as that of the Fallow Deer.—Among the species of deer most nearly allied to the S. are the Wapiti (q. v.), an American species, and several species belonging to the warmer parts of Asia and the north of Africa. They all have round branched antlers, with a basal snag in front, and a tuft of hair on the hind legs above the middle of the metatarsus.

STAG BEETLE (*Lucanus*), a genus of coleopterous insects, of the family *Lamellicornes*, remarkable for the large projecting mandibles of the males

Stag Beetle (*Lucanus cervus*).

which have large denticulations, and somewhat resemble stags' horns. The antennæ terminate in a club composed of many leaflets, disposed on an axis like the teeth of a comb. The COMMON S. B. (*L. cervus*) is one of the largest of British insects, the males being fully two inches long. It flies about in the evening in the middle of summer chiefly frequenting oak-woods. The larva feeds on the wood of the oak and willow, and is injurious to the trunks of trees, into which it eats its way very rapidly. It is supposed to be the *Cossus* of the ancient Romans, much esteemed by them as a delicacy. It lives for several years before undergoing its transformations. In its perfect state, the S. B. is a formidable-looking insect, and its powerful mandibles are capable of inflicting a pretty severe bite, if it is incautiously seized, but it is not venomous. Some of the tropical stag beetles are remarkable for their brilliancy of colour.

STAGE. See THEATRE.

STA'GGERS is a popular term applied to several diseases of horses. Mad or Sleepy Staggers is inflammation of the brain, a rare but fatal complaint, marked by high fever, a staggering gait, violent convulsive struggling, usually terminating in stupor, and treated by bleeding, full doses of physic, and cold applied to the head. Grass or Stomach Staggers is acute indigestion, usually occasioned by overloading the stomach and bowels with tough hard grass, vetches, or clover, a full meal of wheat, or other indigestible food. It is most common in summer and autumn, is indicated by impaired appetite, distended abdomen, dull aspect, unsteady gait; and is remedied by full doses of purgative medicine, such as six drachms of aloes and a drachm of calomel rubbed down together, and given in a quart of thin well-boiled gruel. Frequent clysters, with hand-rubbing and hot water to the belly, are likewise useful. Where the dulness increases stimulants should be freely given.

STAGHOUND, a large and powerful kind of Hound (q. v.), formerly much used in England for hunting the stag, but now almost extinct. It is supposed to be a breed of the old English Southern

Hound. In scent, it is almost equal to the bloodhound; in fleetness, it is inferior to the foxhound. It has great power of endurance, and has been

Staghound.

known to run 50 miles after the stag. It is also courageous, and does not hesitate to attack the stag when at bay.

STAHL, Georg Ernst, a celebrated German physician and chemist, was born at Anspach, 21st October 1660, studied medicine at Jena, and after practising successfully for some time, was called, in 1694, to the chair of Medicine, Anatomy, and Chemistry, in the newly-founded university of Halle; whence he removed to Berlin in 1716, where he was appointed physician to the king of Prussia. He was a member of the Berlin Academy, and died in that city 14th May 1734. According to Blumenbach, S. is to be considered as one of the greatest and most profound physicians the world has ever seen, though the mysticism with which his works are imbued is to be reprehended. S.'s system of medicine, which was a combination of the physiology of Van Helmont (q. v.) with the psychology of Descartes, is founded upon the supposition of the existence of a mysterious force residing in, but independent of, and superior to matter; this force, the *anima* (or 'soul'), not only forms the body, but directs it in the exercise of all its functions, and this, too, sometimes unconsciously; though the way in which this influence is exercised he does not explain. Being subject to error by nature, the 'anima,' by negligence or maladroit action, originates diseases in the body, which it then attempts to cure, through the functional action of the various parts. S. held that art ought only to commence where nature had ended, and to be useful, it should follow a similar course of action; he was also of opinion that plethora, either local or general, was one of the chief causes of disease. His system of therapeutics corresponded with his pathological principles, and was confined mostly to bleeding and the use of mild laxatives. His psychological theory of the connection between the soul and body led him into a discussion with Leibnitz (who had falsely charged him with propounding materialism), from which he emerged victorious on the essential points of their respective theories; though Leibnitz had the advantage in matters of detail. Subsequent physiologists have made S.'s opinions the object of ridicule, though his doctrine of the 'anima' is, under the name of 'vital principle' and 'nature,' generally adopted at the present day; but his supercilious contempt for chemistry as a medical agent has long ceased to be generally upheld. Nevertheless, S. was one of the ablest chemists of his time, destroyed, in his usual trenchant style, numberless absurd opinions which had found their way into the science, and propounded the first theory of combustion (see Phlogiston), which was universally accepted till the time of Lavoisier (q. v.). His works, according to Haller, number 250, but the chief are—*Theoria Medica vera* (Halle, 1707, 1708, 1737), which contains his medical theory, and *Zymotechnia Fundamentalis, seu Fermentationis Theoria Generalis* (Halle, 1697), in which his chemical opinions are set forth. An account of his opinions is found in Haller's *Bibliotheca Medicinæ Practicæ*, vol. iii.; Sprengel's *Histoire de la Médecine;* A. Lemoine's *Le Vitalisme et l'Animisme de Stahl* (Paris, 1864), and numerous other works.

STAINED GLASS. See Glass.

STAINS FOR WOOD. A variety of stains have recently been invented for the purpose of giving to the cheaper kinds of wood, such as deal, &c., the appearance of the more costly kinds. These are chiefly solutions of certain metallic salts, combined with vegetable infusions.

STAI'RCASE. This feature, now so important in all houses, was of small note till about the time of Queen Elizabeth. Previously, stairs were all constructed on a circular plan, revolving round a central axis or newel, and were called turret or corkscrew stairs. During the 16th and 17th centuries, staircases with wide straight flights were first introduced, and were made leading features in the mansions of the Elizabethan style. They had usually massive oak balusters with carved pedestals, and were ornamented with carved panels, pendants, &c. Staircases of this description are still in common use, but are lighter in style, light cast-iron railings being substituted for the heavy oak balustrades.

STAKE NETS. See Salmon.

STALA'CTITES and STALAGMITES are found in caves and other places where water charged with carbonate of lime is subject to evaporation. Water impregnated with carbonic acid is able to dissolve lime, and as all rain and surface water contains more or less carbonic acid, it takes up in its passage through the earth to the roofs of caves a certain amount of lime. When the water is exposed on the roof or floor of the cave, evaporation takes place, and so both the bulk of the water and its solvent power are reduced, and a thin pellicle of solid carbonate of lime is deposited. When this takes place on the roof of the cave, long icicle-like pendants are formed, which are called stalactites; and when the water drops upon the floor, a stalagmitic layer is formed, which rises at the points where the largest supply of material exists, in the form of pillars to meet the overhanging stalactites. In some caves, the descending and ascending points have met, and formed a series of natural columns as if supporting the roof. The colour of the limestone thus formed is affected by the superincumbent strata, but it is generally white or yellowish. The stalactites have a rich subcrystalline structure, being composed of acicular radiating crystals, arranged in concentric layers from their exogenous growth. Sometimes, from metamorphic changes that have taken place subsequent to their formation, they become more truly crystalline. The amount of the deposition is very great in some caves, and the wonderful variety and singular groupings of the stalactites give them a peculiar beauty. The caves most remarkable in

this way are the Cave of Adelsberg in Styria, the Grotto of Antiparos in the Grecian Archipelago, Wyer's Cave in the United States, and the caves of the Peak in Derbyshire.

The remains of primeval man found in the caves in France, and the fossils from the bone caves in Britain and elsewhere, are generally cemented together into a stalagmitic deposit on the floor of the cave.

STALL, a fixed seat enclosed at back, and with elbows at the sides. One or more rows of these extended along each side of the choir of most churches before the Reformation, and fine examples still remain in nearly all the cathedrals. They are generally enclosed at back with a high screen, and covered with canopies ornamented with pinnacles, &c.

STA'LYBRIDGE, a market-town and municipal borough, partly in Lancashire and partly in Cheshire, stands on the Tame, eight miles east of Manchester. It is remarkable chiefly for its cotton manufactures, which are very extensive. The print-works, iron-foundries, and machine-shops are also numerous and important. Free communication by railway is afforded in every direction. There are in S. 39 mills employing 10,000 hands, and 28 foundries and machine shops employing 1100 hands. Pop. (1881) of municipal borough, 22,784.

STAMBOU'L. See CONSTANTINOPLE.

STA'MENS are those parts in the flowers of phanerogamous plants which excite the pistil to the formation of the fruit, and thus effect fertilisation or Fecundation (q. v.). A stamen consists of a receptacle—the *anther;* which contains a dust—the *pollen*—various in colour, but generally yellow, and is generally supported on a stalk called the *filament;* the anther being the blade of a metamorphosed leaf, and the filament the leaf-stalk. The filament is, however, sometimes awanting, and the anther is then said to be *sessile.* Each anther generally consists of two cells, forming two lobes, which, before they open to give forth the pollen, are again divided into two cell-like parts, and at the time of their maturity open by longitudinal clefts, by pores, or by valves, to scatter the pollen, which is conveyed to the stigma either by its own falling, by the wind, or by the insects which seek honey in flowers. See PISTIL. The pollen consists of single cells, which are usually free; more rarely,

Stamens.

the pollen of each cell is united into a mass, called the *pollen-mass* or *pollinium*, as in the *Orchideæ* and *Asclepiadaceæ.* The stamens are either found along with the pistil in the same flower, and are then arranged around it, in which case the flower is *hermaphrodite;* or they are placed by themselves in separate flowers, which are therefore called *male* flowers. The stamens are sometimes united together, generally by the filaments, which form a tube, and the flower is *monadelphous;* sometimes, by their union, they form two sets, when the flower is *diadelphous;* sometimes three or more, when it is *polyadelphous;* and the filaments are sometimes united with the pistil into a column, from which the anthers spring, as if they grew from the pistil, when the flower is *gynandrous.* See BOTANY. The stamens form either one or more whorls, and when in one whorl are either opposite to the petals or alternate with them. The latter is regarded as their normal position. Sometimes, by abortion, there is only one stamen. Being leaf-organs, stamens arise from the axis; but they very frequently grow upon the corolla, so that they seem to derive their origin from it. When the stamens seem to arise from the corolla or from the calyx, they, and also the flower, are said to be *perigynous* (Gr. *peri*, around, and *gyne*, a wife); when they grow from the pistil, they are *epigynous* (Gr. *epi*, upon); and when from beneath it, *hypogynous* (Gr. *hypo*, under). These distinctions have been much made use of, by Jussieu and others, in classification. The transition of petals into stamens can be easily traced in some flowers, for example, in the Water Lily. In double flowers, the stamens have been changed into petals. Linnæus adopted the stamens as the means of his division of plants into classes (see BOTANY); but in so far as the classification was founded on their mere number, it was artificial, the number of stamens being various in plants very closely allied. Stamens are among the organs of plants which most frequently display Irritability (q. v.).

The filament assumes a great variety of forms. Sometimes it is short and thick, sometimes long and slender; sometimes dilated at the base; sometimes petal-like, with the stamen at its tip; sometimes forked, or divided into three teeth, of which the central one bears the anther; sometimes bent or jointed, sometimes spiral. The form of the anther varies still more than that of the filament; indeed, the variety of forms is endless. The *connective* is a body which unites the lobes of the anther. When the filament is continuous with the connective, the anther-lobes seeming to be united to it through their whole length, the anther is said to be *adnate* or *adherent;* when the filament ends at the base of the anther, the anther is *innate* or *erect.* In many flowers, as in those of grasses, the anther is attached to the filament by a mere point, and is very movable, easily turned by the wind. It is then said to be *versatile.*

STA'MFORD, an ancient market-town and a parliamentary and municipal borough of Lincoln, on the Welland, which is navigable hence to the sea, 11 miles north-west of Peterborough. Agriculture is almost the exclusive pursuit of the inhabitants of the district around, and S. is chiefly remarkable for its ancient remains. It first appears in history in 449, when the Britons and Saxons here defeated the Picts and Scots. Many of the Jews of S. were slain, and the whole community plundered in 1190 by those who had enlisted for the Crusade. In the middle ages several parliaments and councils were held here, and the town contained about 16 churches, and a number of religious houses. In 1572, a number of Flemish Protestant refugees settled here, and introduced the weaving of silk and serge. Portions of the walls and gates of the Carmelite and Franciscan priories, as well as other curious remains, are still extant. There are numerous schools and other important institutions. Pop. (1881) 8775. S. returns a member to the House of Commons.

STAMFORD, a township and borough of Connecticut, U. S., at the entrance of Mill River into Long Island Sound, 36 miles north-east of New York, on the New York and New Haven Railway. It is a favourite residence and summer resort of opulent

New Yorkers. It has 2 banks, newspaper, 8 churches, a small coasting-trade, and manufactures of iron, boots and shoes, dye-stuffs, carriages, coal oil, &c. Pop. in 1860, 7185; 1880, 11,298.

STA'MMERING AND DEFECTIVE SPEECH. Stammering is an affection of the vocal and enunciative organs, causing a hesitancy and difficulty of utterance, and respecting the nature and the origin of which a variety of different opinions has been entertained. Stammerers themselves often attribute the varying conditions of their impediment to causes which must be purely imaginary, such as the state of the wind, the changes of the moon, &c. There can be no doubt that the impediment is aggravated by depression of spirits, derangement of the digestive organs, physical debility, &c.; but these influences have nothing to do with the primary cause of the infirmity. A nervous dread of speaking is usually associated with stammering; but this is rather the result than the cause of the impediment. If constitutional nervousness were productive of stammering, the number of sufferers would be vastly greater, and it would include a larger proportion of females than of males; whereas the robust sex furnishes by far the greater number of cases; and it is noticeable, besides, that stammerers are not in general persons of weak nerves, otherwise than in connection with the act of speaking. Any physical defect will render a person nervous when the peculiarity is made a subject of observation, and it is in this way only that nervousness is associated with speech in cases of stammering. The strength of this impediment lies in *habit*, in mismanagement of the breath and the organs of utterance, rendered habitual before the development of reason and observation; and the removal of the defect depends on the acquirement of voluntary control over the mechanical agents of speech. The nervousness which unfits the stammerer for self-direction gradually subsides as his will attains a mastery over the processes of speech; and perseverance in a discipline of systematic and guarded utterance rarely fails to remove the impediment, and the fear which accompanied it.

The first manifestations of stammering usually take place during the weakness attendant on disease, or after a fall or sudden fright; but sometimes the impediment appears to arise from imitation, and children have been known to be infected by even the most casual example. Thus, when one member or visitor of a family stammers, the younger members of the family are very apt to be similarly affected. From this cause defects of speech run so much in families, that many persons have thought them to be hereditarily transmitted. This, however, is altogether a mistake. In the early stages, a little patient direction on the part of parents and nurses would suffice to check the tendency to stammer, and prevent the formation of the unfortunate habit.

Stammering generally begins about the fourth or fifth year of age; but harshness in checking children, or impatience in connection with messages or lessons, may induce the impediment at a considerably later period. Boys of ten or eleven years of age have been excited into the habit by injudicious hurry and peremptoriness at school. The little stammerer, when he cannot be more directly assisted, should be kindly counselled to take time and speak slowly, and he should by no means be ridiculed or reproved for what he cannot help, and is not taught how to avoid.

The varieties of stammering are so great, that scarcely two cases are found precisely alike. In some there is but little outward manifestation of effort; in others, the futile attempts are painfully demonstrative. The silent straining to speak causes the eyeballs to protrude, and the veins of the face and neck to swell, till relief from apparent choking comes in fitful, ungovernable bursts of sound. In almost all cases the head oscillates loosely on the neck, and is forced upwards by the misdirected current of breath; while the larynx, the organ of sound, is from the same cause agitated in continual efforts to ascend, and the voice is consequently abrupt and intermittent, and unnaturally acute. The muscles of the face participate in the general upward action, and sometimes the spasmodic contortions extend over the whole body, causing the stammerer to rock in his chair, or start wildly to his feet. These muscular disturbances arise simply from disordered respiration, and they disappear when the habit of closing the glottis and compressing the organs of articulation is overcome, and the air is allowed to pass freely in or out of the lungs.

The terms stuttering and stammering are often used synonymously, but the former term is properly, or, at least, conveniently, limited to a loose and imperfect action of the organs of articulation, as distinguished from the irregularity of breathing and the convulsive and choking symptoms which invariably accompany stammering. In stuttering, the organs meet and rebound again and again in reiteration of syllables before words can be fully formed. The source of this difficulty lies mainly in the lower jaw. When this organ is brought under control, and the effort of speech is transferred from the mouth to the throat—where all voice is formed—the power of fluency is readily obtained. But stuttering is rarely unaccompanied by some degree of spasmodic stammering, and the two forms of impediment, while theoretically distinct, are generally blended in mutual aggravation.

Stammering is, in nearly every case, perfectly curable, as it seldom arises from organic defect. The means of cure must, however, often be continued for a length of time before the stammerer is free from the danger of relapse. The best time for the cure is undoubtedly the earliest, before the habit has acquired full strength, and before the sufferer has endured the most grievous mortifications and drawbacks of the impediment. But the adult stammerer generally brings to the curative task a higher appreciation of its importance, and a greater care and concentration of effort than the child is capable of; and these qualities almost compensate for the disadvantage of long-established habit. Parents often unwisely defer the attempt to correct impediments of speech, in the hope that the defects will disappear as the child gains strength and reaches riper years. But the hope is very rarely realised; and were it otherwise, the misery of years of impediment, and the hindrance to education which stammering certainly involves, are evils to be avoided by all possible means. With this, as with all habits, 'prevention is better than cure;' and stammering would be easily and certainly prevented by timely advice carried out with ordinary care in the nursery.

The means that have been proposed for the cure of stammering have been as various as the theories of the nature of the defect; and sometimes the 'cure' has been apparently but little better than the disease. Drawling, singing, interpolations or elisions of letters, speaking with the teeth closed, or with the tongue pressed to the roof of the mouth, sniffling, whistling between words, beating time to utterance, stamping the foot, jerking the body, forks on the tongue, pebbles in the mouth, or tubes fixed between the organs, bands compressing the larynx, and other absurd and uncouth devices, have been, under cover of expedient secrecy, practised on unhappy stammerers. But the removal of this defect

as above shewn, depends on the skilful application of scientific principles, respecting which there is no mystery save that which arises from the little attention that has been paid to the science of speech.

From the preceding account of the nature of stammering, it is almost superfluous to add that the cure of this impediment does not fall within the province of surgery. Yet the barbarous operation of cutting a wedge from the root of the tongue—introduced from Germany about 30 years ago—and the equally futile and cruel operation of excising the tonsils, have been, within no distant date, extensively practised by surgeons in Great Britain.

The habit of stammering can only be counteracted by the cultivation of a habit of correct speaking; and the latter can only be acquired by studying the processes of speech, the relation of breath to articulate sounds, the positions of the tongue and the other oral organs in moulding the outward stream of air; and by a patient application of these principles in slow and watchful exercise. The lungs constitute a pair of bellows, and the mouth, in all its varying shapes, the nozzle of the bellows. The passage of the throat must be kept open, and the breath expelled by means of the ascent of the diaphragm, not by downward pressure of the chest. All sound originates in the throat, and all effort in speech must be thrown back behind the articulating organs, which must be kept *passive*, yielding to the air, always opening to give it exit, and never resisting it by ascent of the tongue or of the jaw. The head must be held firmly on the neck, to give free play to the attached organs; and the great principle must never be lost sight of that *speech is breath*; and that, while distinctness depends on precision and sharpness of the oral actions, *fluency* depends on the unrestrained emission of the material of speech—the air we breathe.

Besides stammering and stuttering, there are many other forms of vicious articulation, which are rather defects than impediments of speech. The elementary sounds most subject to mispronunciation are those of *r* and *s*, giving rise to the common defects of burring and lisping. Burring consists in vibrating the uvula or the edge of the soft palate, instead of the tip of the tongue; and lisping consists in applying the tongue to the teeth or the gum, so as to intercept the breath, and force it over the sides instead of the centre of the tongue. The sound of *l* also is often defective, *w*, *y*, *ng*, or a *vowel* being substituted for the lingual articulation. Other substitutions of one element for another are common, such as *t*, *d*, and *n*, for *k*, *g*, and *ng*; *s* or *z* for *th*; *s* for *sh*, &c. There are also defects which arise from organic malformation, and require the aid of surgery; as when fissure exists in the palate, and the breath cannot be enclosed behind the lips or tongue, but escapes into the nostrils; when the tongue is too closely tied to the bed of the mouth, and the tip cannot be raised to the palate; when the teeth are so irregular or abnormally numerous as to leave the tongue too little room to act, &c. In some cases the breath escapes into the nostrils when there is no organic cause for the peculiarity, and *r*, *l*, *s*, and other elements are nasally affected, merely from habit. The nasal passages are, in other cases, insufficiently free, and *m*, *n*, and *ng* are scarcely distinguishable from *b*, *d*, and *g*.

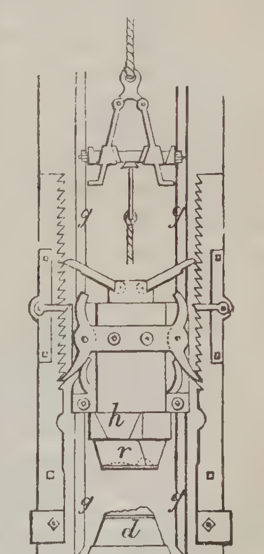
There are comparatively few persons who have perfect command over their vocal organs. Speaking, which is in reality an art, is exercised only as an instinct; and thus, as an eminent American author (Dr Rush) observes, 'some men only bleat, bark, whinny, or bray a little better than others.' It is some consolation to those who have been compelled by defects to study the art of speech, that they exercise the crowning faculty of man's nature more worthily than others, and thus become, perhaps, better speakers than they would have been without the stimulus of defect or impediment.

Speaking, when the respiration is properly conducted, is one of the most healthful exercises; but violent or long-continued effort is injurious to the chest, when the lungs are not kept well inflated. Frequently, also, under such circumstances, the vocal chords become permanently relaxed, and total loss of voice sometimes ensues.

The acquirement of the power of speaking in infancy is dependent on the possession of hearing, so that deaf children are also mute. Under proper training, however, they may be taught to articulate, as the organs of speech are very rarely imperfect. Children who have been subject to fits or other cerebral affections, or who are deficient in imitative power, are sometimes very backward in learning to speak. In such cases, great care is requisite to direct the early attempts, and prevent the formation of bad habits. Many of the worst forms of defect and impediment owe their origin simply to the want of proper direction in the production of elementary sounds, when the little sufferers have failed to enounce them correctly by natural imitation.

It is unnecessary to enumerate the various English, American, and foreign authors who have propounded conflicting theories of the cause, and schemes for the cure of impediments of speech. Of the systems practised in England at the present day, those of Dr Hunt and Mr Melville Bell have been most fully published. The views of these authors differ but little, and are in substance the same as those contained in this article.

STAMPING OF METALS. There are different kinds of stamping. The plan adopted for producing coins or medals is described under MINT, and the preparation of the dies used, under DIE-SINKING. For the ordinary stamped brass-work, so extensively made in Birmingham, a stamping-machine is employed, of which the essential parts are a *die*, a *reverse* or counter-die, and a *hammer*. It is shewn in the annexed figure; but the toothed rack, with arrangement for catching the hammer after it rebounds, is only used for special purposes. The die *d*, which is made of cast iron or steel, is fixed to the bottom of the stamp, and the reverse, *r*, is attached to the hammer *h*, which works between two guides *g*, *g*. Pieces of thin rolled brass are cut to size, and one placed upon the die; the hammer, with the counter-die, is now raised to a sufficient height by a windlass and rope, or other means, and allowed to fall, and thus force the thin plate into the die. The plates from the first blow are then annealed. Repeated blows and annealings follow until the article is 'brought up,' slight alterations



Stamping-machine.

in the reverse being from time to time required. Sometimes as many as 30 blows are necessary, but 10 or 12 strokes will suffice for an object with a considerable depth of raising. Globular articles are stamped in two or more pieces, and then soldered together.

The stamping process was first adapted to the production of hollow shapes in sheet-iron by Mr T. Griffiths, in 1841; and since then, the manufacture of such goods as dish-covers, basins, and teapots has been improved and extended to a surprising extent. In the case of a dish-cover, for example, a single sheet of iron is brought to the required shape by repeated stampings and burnishings upon a chuck. It is afterwards tinned with great ease, there being no joints to interfere with the operation; for the same reason, iron basins stamped out of a single sheet can be readily enamelled. The old way of forming these articles by hand-labour was very tedious and clumsy.

German silver is too brittle a metal to be stamped like brass or iron, consequently it has only hitherto been made into small objects, such as spoons and forks, by this process. But the Messrs Elkington of Birmingham are now making articles of considerable size in this material, by means of a stamping-press worked by hydraulic power. A number of graduated dies are used for one object, each pair coming gradually nearer the desired shape, but none of them making an impression deep enough to strain the metal.

For stamping-machines used in dressing metallic ores, see METALLURGY.

STAMPS, or STAMP DUTIES, are taxes imposed on all parchment and paper whereon private deeds or other instruments of almost any nature are written. It is a convenient mode of raising the public revenue, and was first instituted by a statute of 5 and 6 Will. and Mary, c. 21. A stamp tax was imposed for the first time by the United States after the war of the Southern rebellion.

STA'NCHIONS, or STANCHELS, upright iron bars fixed in the stonework to protect windows. They are sometimes let into the stone at top and bottom; sometimes at bottom only, and ornamented with fleurs-de-lis, &c., at top.

STA'NDARD. In its widest sense, a standard is a flag or ensign under which men are united together for some common purpose. The use of the standard as a rallying-point in battle takes us back to remote ages. The Jewish army was marshalled with the aid of standards belonging to the four tribes of Judah, Reuben, Ephraim, and Dan, and the Egyptians had ensigns with representations of their favourite animals. The flag of Persia was white, and, according to Xenophon, bore in his time a golden eagle with expanded wings; it was fixed on a chariot, and thus conveyed to the field of battle. Æschylus, in enumerating the six chiefs who, headed by Polynices, set themselves in battle array against Thebes, describes the device on the standard of each. In the earliest era of Roman history, a bundle of hay or fern is said to have been used as a military standard, which was succeeded by bronze or silver figures of animals attached to a staff, of which Pliny enumerates five—the eagle, the wolf, the minotaur, the horse, and the boar. In the second consulship of Marius, 104 B.C., the other animals were laid aside, and only the eagle retained; and down to the time of the later emperors, the eagle, often with a representation of the emperor's head beneath it, continued to be carried with the legion. On the top of the staff was often a figure of Victory or Mars. Each cohort had also an ensign of its own, consisting of a serpent or dragon woven on a square piece of cloth, and elevated on a gilt staff with a cross-bar. Under the Christian emperors, the *Labarum* (q. v.) was substituted for the imperial standard. Various standards of great celebrity occur in medieval history, among which may be enumerated the Flag of the Prophet (q. v.); the standard taken from the Danes by Alfred of England; and the Oriflamme, originally belonging to the Abbey of St Denis, and borne by the Counts of Vexin, which eventually became the standard of the French kingdom.

In strict language, the term standard is applied exclusively to a particular kind of flag, long in proportion to its depth, tapering towards the fly, and, except when belonging to princes of the blood-royal, slit at the end. Each baron, knight, or other commander in feudal times, had a recognised standard, which was distributed among his followers. The length of the standard varied according to the rank of the bearer. A king's standard was from 8 to 9 yards in length; a duke's, 7 yards; a marquis's, 6½ yards; an earl's, 6 yards; a viscount's, 5½ yards; a baron's, 5 yards; a banneret's, 4½ yards; and a knight's, 4 yards. There was never a complete coat-of-arms on the standard; it generally exhibited the crest or supporter with a device or badge of the owner, and every English standard of the Tudor era had the cross of St George at the head. Standards were registered by the heralds, and the charges on them selected and authorised by an officer of arms.

The so-called Royal Standard of Great Britain is more properly a Banner (q. v.), being a square flag with the national arms covering the entire field without any external accessories. The so-called cavalry standards in use in the British army are also in strictness banners. They are small in size; their colour is determined by the colour of the regimental facings, and they are charged with the cipher, number, insignia, and honours of the regiment. The banners of the household troops are, however, all crimson and richly embroidered with the royal insignia of England. Corresponding to the standards of the cavalry are the colours of the infantry regiments, of which each has 'a pair,' one, called the Queen's colour, being the Union Jack (q. v.), charged with some ornamental device; the other, the regimental colour, with the cipher, number, device, motto, and honours of the corps, cantoned with a small union jack. When a regiment obtains new colours, they are usually given by the wife of the colonel, or some lady of distinction.

STANDARD, BATTLE OF THE, a battle between the English and Scots which took place on Cutton Moor, near Northallerton, when the latter were defeated with great loss. On the usurpation of Stephen, David I. of Scotland, who, along with Stephen, had sworn to defend the rights of Matilda, daughter of Henry I., invaded England in pursuance of his oath, and compelled the barons of the northern part of the kingdom to swear fealty to that princess. After a war of nearly three years' duration, David encountered the English troops at Cutton Moor, on 22d August 1138, with a large but undisciplined army, who, partly in consequence of a rumour that the king was slain, were thrown into confusion, and the most disastrous rout followed, in which the Scots are said to have lost 10,000 men. The battle derived its name from the circumstance that a ship's mast, bearing on its summit the consecrated host, and surrounded by the banners of St Peter of York, St John of Beverley, and St Wilfred of Ripon, elevated on a wagon, marked the centre of the English army.

STANDARDS. In Carpentry, the quarters or

upright posts in wooden partitions are so called. The upright timbers to which doors are hung are called door-standards.

STANDING ORDERS is the name given to those permanent regulations which may be made by either House of Parliament for the conduct of its proceedings, and are binding on the House by which they are made as continual by-laws enduring from parliament to parliament unless rescinded. A standing order of the House of Lords, when rescinded, is said to be *vacated;* in the Commons the corresponding term is *repealed.* In the Lords, a motion for making or dispensing with a standing order cannot be granted on the same day that the motion is made, or till the House has been summoned to consider it; and every standing order, as soon as agreed to, is added to the 'Roll of Standing Orders,' which is carefully preserved and published from time to time. In the House of Commons there was, until 1854, no authorised collection of standing orders, except such as related to private bills. In that year a manual of rules, orders, and forms of proceeding relative to public business was drawn up and printed by order of the House.

Standing orders are occasionally suspended when it is desirable that a bill should be passed with unusual expedition.

STANDING STONES. Large rude unhewn blocks of stone, artificially raised to an erect position at some remote period, have been found in almost every part of the world where man has fixed his habitation. We find them in Britain, in continental Europe, in Assyria, India, Persia, and even in Mexico, and they are generally of such a size that their erection presupposes some degree of skill in the use of mechanical power. They are especially abundant in the British Isles, where they sometimes stand singly, and sometimes in more or less regular groups; and it was long the general opinion of archæologists that they were connected with the Druidical worship of the Celtic races. The result of modern investigation has been to throw doubts on the Druidical theory, while no other explanation has been given which is in all cases satisfactory. The erection of a large stone not easily shifted from its place is perhaps the earliest mode which man's instinct would contrive of preserving the memory of an event or of a hero; and there can be no doubt that many of these monoliths mark the site of a grave or of a battlefield. Human skeletons, and bronze and iron weapons, have been in numerous cases found underneath them. A traditional remembrance of this origin is preserved in the name of 'Cat Stane' (from Celtic *cath,* battle), given to some of them in Scotland, and 'bauta stein' (battle stone) in Norway. Another possible purpose is preserved in the Scottish name of 'hair stane,' or boundary stone, by which they are occasionally known; not a few of them, whatever their original object, having been long used as landmarks, and being alluded to as such in very early charters. A third use of these monoliths is at least as old as the historical books of the Old Testament. We read in Judges ix. 6, of Abimelech being made king 'by the pillar which was in Shechem,' and in 2 Kings xi. 14, of Joash, when he was anointed king, standing 'by a pillar, as the manner was;' and a like usage prevailed in ancient Britain, where the king or chief was elected at the 'Tanist stone' (from *Tanist,* the heir-apparent among the Celts), and there took a solemn oath to protect and lead his people. A very celebrated stone of this kind was the Lia Fail of Ireland, which was brought to Icolmkill for the coronation of Fergus Erc; and after being removed to Scone, became the coronation stone of Scotland, till conveyed away by Edward I. to Westminster, where it now forms part of the coronation chair of the sovereigns of the United Kingdom. In all these cases there is an idea of a solemn religious sanction attached to the stone; and a peculiar degree of sacredness seems to have invested any contract entered into at one of those perforated stones which are or were occasionally to be met with in England and Scotland. Such a stone, with an oval hole large enough to admit a man's head, till lately adjoined the monolithic group of Stennis in Orkney. It was known as the 'Stone of Odin,' and continued till the middle of last century to be the scene of the interchange of matrimonial and other vows, he who broke the vow of Odin being accounted infamous. It is said to have been the popular belief that any one who had in childhood been passed through the opening would never die of palsy. The power of curing rheumatism was ascribed to a perforated stone at Madderty in Cornwall. While many of the monoliths in Britain are undoubtedly of a very remote age, there are some indications that the practice of erecting them continued for a time after the introduction of Christianity, and that they were used to subserve purposes connected with the new faith. A series of monoliths in the island of Mull are traditionally said to have been guide-posts to pilgrims visiting Iona, and it has been suggested that they point out the route which St Columba must have pursued on his way to the residence of the Pictish king, Brude Mac Meilochon.

Still more puzzling to archæologists than the single monoliths are the large symmetrical groups of them, of which the most remarkable are Stennis in Orkney, Stonehenge and Avebury in Wiltshire, and Carnac in Brittany; all which, till lately, existed comparatively entire, though they have all been in the memory of the present generation more or less despoiled for building purposes. The most imposing of these monuments is Stonehenge (q.v.). At Stennis, from 70 to 80 stones were grouped in two separate circles of 360 and 100 feet diameter respectively, the largest stones being in the smaller circle. At Avebury, two double concentric circles were surrounded by an outer circle of 100 stones, the whole being approached by two long avenues of stones in double lines. In all these, and other instances, the circles were surrounded by a trench

Standing Stones of Stennis.

and mound. At Carnac the stones are placed not in circles but in straight lines, with a curved row at one end—an arrangement which has suggested the idea of a burial-place on the site of a great battlefield. All around Carnac, as well as Stonehenge,

Barrows and Cromlechs (q. v.) are to be found. While the popular notion of all these monuments is that they were Druid temples, the circular form so frequent among them has also suggested the idea that they may originally have been connected with the worship of the sun, and it is not impossible that they may have been used in turn for the successive religious worship of different races. They seem also to have served the purpose of courts of justice, or battle-rings for the duel and judicial combat. See STONEHENGE.

A remarkable description of monument, whose purpose is utterly unknown to us, is the *Rocking-stone* or *Logan-stone* (q. v.). Standing stones ornamented with a peculiar description of sculpture are found largely in Scotland. See SCULPTURED STONES.

STANFIELD, CLARKSON. See SUPP. in Vol. X.

STANHOPE, LADY HESTER LUCY, the eldest daughter of Charles, third Earl Stanhope, and his wife Hester, daughter of the great Lord Chatham, was born on the 12th March 1776. She grew up to be a woman of great personal charm, and of unusual force and originality of character. Very early she went to reside with her uncle, William Pitt, and as mistress of his establishment, and his most trusted confidant during his season of power, and till his death, she had full scope for the exercise of her imperious and queenly instincts. On the death of Pitt, a pension of £1200 a year was assigned her by the king. Mr Fox proposed to provide for her much more munificently, but she proudly declined his offers, as unwilling to accept benefit at the hands of the political enemy of her dead uncle. The change from the excitements of a public career, as it might almost be called, to the life of an ordinary woman of her rank with means somewhat insufficient, was naturally irksome to her, and in 1808, she was tried still further by the death, at Coruña, of her favourite brother Major Stanhope, and of Sir John Moore, for whom she is known to have cherished an affection. The precise relations between them have never been made known; but the last words spoken by the dying hero were: 'Stanhope' (a Captain Stanhope of his staff, who stood by him), 'remember me to your sister.' Conceiving a disgust for society, she retired for a time into Wales, and in 1810, she left England never to return to it. In mere restlessness of spirit she wandered for a year or two on the shores of the Mediterranean, and finally settled herself among the semi-savage tribes of Mount Lebanon. Here she led the strangest life, adopting in everything the Eastern manners, and by the force and fearlessness of her character, obtaining a curious ascendency over the rude races around her. She was regarded by them with superstitious reverence as a sort of prophetess, and gradually came so to consider herself. With the garb of a Mohammedan chieftain, she adopted something of the faith of one, and her religion, which seems to have been sincere and profound, was compounded in about equal proportions out of the Koran and the Bible. Her recklessly profuse liberalities involved her in constant straits for money; and her health also giving way, her last years were passed in wretchedness of various kinds, under which, however, her untamable spirit supported her bravely to the end. She died in June 1839, with no Frank or European near her, and was buried in her own garden. The main sources of information about her are the notes of the frequent travellers who visited her in her strange seclusion, and the *Memoirs* derived from her own lips, and afterwards (3 vols. Lond. 1845—1846) published by a medical gentleman who went abroad with her, and from time to time lived with her in her retirement.

STANHOPE, PHILIP HENRY, EARL, historian and biographer, was descended from one of the best families of England, boasting three peerages—Chesterfield, Stanhope, and Harrington. This branch springs from the Stanhopes, Earls of Chesterfield. Its founder was the Hon. Alexander Stanhope, a distinguished diplomatist in the reigns of William III. and Queen Anne, who was son of the first Earl of Chesterfield by his second marriage. James, first Earl Stanhope, was an eminent military commander, who effected the reduction of the celebrated port of Mahon, in the island of Minorca, but who was subsequently with his army captured in Spain by the Duke of Vendome. He was the favourite minister of George I., who made him First Lord of the Treasury, and Chancellor of the Exchequer. He was created an earl in 1718. His statue, by Kent and Rysbrach, occupies a conspicuous place in Westminster Abbey. His grandson, the third earl, born 1753, and distinguished for his mechanical genius and scientific researches, died 1816. He was the inventor of a printing-press which bears his name, an arithmetical machine, and a monochord. This Lord S. was connected with the Pitts by marriage, having married Lady Hester Pitt, daughter of the great Earl of Chatham. Lady Hester Stanhope (q. v.) was a daughter of this marriage.

The subject of this notice, only son of the fourth earl, was born at Walmer, 1805. His courtesy title was Viscount Mahon. He received a private education, but graduated at Oxford, where he took his B.A. degree, 1827; created D.C.L., 1834. He entered the House of Commons in 1830 for Wooton Bassett, and afterwards sat for Hertford from 1835 to 1852. He was greatly instrumental in 1842 in securing the passing of the Copyright Act (q. v.); was Under-secretary for Foreign Affairs during the brief Peel administration, 1834—1835; and Secretary to the Indian Board of Control under the same minister, 1845—1846. He was a moderate Conservative in politics, and was warmly attached to Sir R. Peel, who named him one of his literary executors. His contributions to history are numerous and valuable. Macaulay, in a review of one of his earliest works, the *War of the Succession in Spain*, accredits him with some of the most valuable qualities of a historian, viz., perspicuousness, conciseness, 'great diligence in examining authorities, great judgment in weighing testimony, and great impartiality in estimating characters.' His most considerable work, *A History of England from the Peace of Utrecht to the Peace of Versailles* (1713—1783), in 7 vols., is a valuable contribution to modern history. His *Life of the Right Hon. W. Pitt* is better than that of Gifford, and more complete than that which was interrupted by the death of Bishop Tomline. S. had access to the entire series of letters from George III. to his favourite statesman; Pitt's familiar letters to his mother and elder brother; and his confidential correspondence with his friend and colleague Dundas deposited at Melville Castle and Arniston, near Edinburgh. His other works include a *History of Spain under Charles II.*, being for the most part extracts from the correspondence of the Hon. Alexander Stanhope, British minister at Madrid from 1690 to 1700; a *Life of the Great Condé*; a *Life of Belisarius*; a volume of *Historical and Critical Essays*, contributed to the *Quarterly Review*, and containing the *Story of Joan of Arc*, since reprinted separately; and a volume of *Miscellanies*. Of the *Life of Condé*, it may be remarked that it was originally written by the author in the French language, and that the English work is really a translation, executed under his superintendence

He also, in conjunction with the Right Hon. E. Cardwell, and under the title of *Memoirs of Sir R. Peel*, published the narratives drawn up by that minister on the Roman Catholic Question; the Peel Ministry of 1834—1835; and the Corn Laws. S. also published an edition of *Lord Chesterfield's Letters*, prefixed to which is the sketch of Lord Chesterfield's life and character, published in his *History of England*. He was mainly instrumental in procuring the appointment of the Historical Manuscripts Commission. He was elected President of the Society of Antiquities, 1846; Lord Rector of the University of Aberdeen, 1858; and one of the six foreign members of the Academy of Moral and Political Sciences at Paris, May 11, 1872. He died December 24, 1875.

STANISLA'WOW, or STANISLAU, a town in the Austrian crownland of Galicia and Lodomeria, pleasantly situated between two branches of the Bistricza, 75 miles south-east of Lemberg. It is the seat of active trade and manufactures. Pop. 13,047.

STANLEY, THE RIGHT HON. EDWARD HENRY SMITH, Earl of Derby, an eminent English statesman, eldest son and heir of the 14th Earl of Derby (q. v.), was born at the family-seat, Knowsley Park, Lancashire, July 21, 1826, was educated at Rugby, and at Trinity College, Cambridge, where he concluded a distinguished university career by taking a first class in classics in 1848, together with a declamation prize and mathematical honours. He early adopted the profession of statesmanship, and especially applied himself to the study of social and economical questions. During his absence on a tour in Canada, the United States, and the West Indies, he was elected (December 1848) M.P. for King's Lynn, on the death of Lord G. Bentinck. He afterwards visited the East, and was still in India when his father received the Queen's commands to form an administration, in which S. was appointed Under-secretary for Foreign Affairs. In 1855, on the death of Sir W. Molesworth, Lord Palmerston paid him the compliment of offering him the seals of the Colonial Office. The offer was declined; but in 1858 he was appointed to the Secretaryship of the Colonies in Lord Derby's administration, and was soon called upon to succeed the Earl of Ellenborough (q. v.) as President of the Board of Control for the affairs of India. The great Indian mutiny had not yet been quelled, and it devolved upon S. to frame resolutions and bring in a bill abolishing the East India Company (q. v.), and transferring their Indian possessions to the direct government of the crown. This duty he performed with consummate ability. The great mutiny was put down during his secretaryship, and in February, 1859, he had to meet the legacy of financial disorganisation which it bequeathed. The Derby government resigned before S. could carry out his plans for establishing the finances of India on a sounder basis, but he gave effective support to his successor in office, in reducing the military expenditure, and by other measures of administrative improvement. When his party went into opposition he kept himself resolutely in the background. On the formation of a new ministry by his father, in June, 1866, he was made Secretary of Foreign Affairs, which office he held until 1868. In May, 1867, he presided at the European conference which met in London to settle the dispute between France and Prussia. He favoured the abolition of church rates, and has been described, with apparent truth, as 'by nature—and, as it would seem, by opinion—a cold, strong-headed reasoning Liberal.' In April, 1869, he was installed Lord Rector of the University of Glasgow, and in October of the same year, on the death of his father, he became Earl of Derby, and took his seat in the House of Lords. On the formation of another Conservative cabinet in 1874 by Mr Disraeli, he was reinvested with the Secretaryship of Foreign Affairs. He has distinguished himself by the support he has given to Workingmen's Institutes, and to the cause of popular education. His speeches are remarkable for admirable good sense and practical philosophy.

STANLEY, THE VERY REV. ARTHUR PENRHYN, D.D., an eminent scholar and divine of the Church of England, was the son of the late Edward Stanley D.D., Bishop of Norwich, and nephew of the lat Lord Stanley of Alderley. He was born 13th December, 1815, while his father was rector of Alderley, and resided there. Educated at Rugby under the care of Dr Arnold, he passed (1834) as an Exhibitioner to Balliol College, Oxford, where he achieved a brilliant reputation, winning the Ireland Scholarship, and taking a first class in classics (1837), the Latin essay prize (1839), and the English essay and theological prizes (1840). In 1838 he was chosen a Fellow of University College, of which he was tutor and examiner for many years. Appointed Canon of Canterbury (1851), Professor of Ecclesiastical History at Oxford, Canon of Christ Church, and Chaplain to the Bishop of London (1858), he succeeded Archbishop Trench in 1864 as Dean of Westminster. He was also chaplain to the Prince of Wales, and chaplain-in-ordinary to the queen. In 1863 he married Lady Augusta Bruce, daughter of the 7th Lord Elgin. S. was one of the most accomplished and liberal theologians of the present age, and may be fairly regarded as the leader of the 'Broad Church' party, having taken an active part in the formidable minority within the church of the upholders of Bishop Colenso. In virtue of his great literary genius, his solid acquirements, his manly sense, and his sympathetic and generous piety, he ranked among the most eminent and estimable of Christian teachers. His principal writings, besides his contributions to Smith's Classical Dictionaries, are the *Life of Dr Arnold* (1844), *Sermons and Essays on the Apostolical Age* (1846), *Memoir of Bishop Stanley* (1850), *The Epistles to the Corinthians* (2 vols. 1854), *Sinai and Palestine* (1855), *Sermons on the Unity of Evangelical and Apostolical Teaching* (1859), *Lectures on the Eastern Church* (1861), *Lectures on the Jewish Church* (1863–1865), *Sermons on various Subjects preached before the University of Oxford* (1860–1863), *Memorials of Westminster Abbey* (1867), *The Three Irish Churches* (1868), *Essays on Church and State* (1870), *The Athanasian Creed* (1871), and *Lectures on the History of the Church of Scotland* (1872). He died July 18, 1881.

STA'NNARIES (Lat. *stannum*, tin), the mines from which tin is dug. The term is most generally used with reference to the peculiar laws and usages of the tin mines in the counties of Cornwall and Devon. By an early usage peculiar to these counties, the prerogative of the crown, elsewhere reaching only to gold and silver mines, is extended to mines of tin, which are the property of the sovereign, whoever be the owner of the soil. A charter of King John to his tinners in Cornwall and Devonshire, of date 1201, authorised them to dig tin, and turf to melt the tin, anywhere in the moors, and in the fees of bishops, abbots, and earls, as they had been used and accustomed—a privilege afterwards confirmed by successive monarchs. When Edward III. created his son, the Black Prince, Duke of Cornwall, he at the same time conferred on him the Stannaries of Devon and Cornwall, which were incorporated in perpetuity with the duchy. Their administration is committed to an officer called the Lord Warden of the Stannaries, who has two substitutes or vice-wardens, one for Cornwall, and

as

one for Devon. In former times, representative assemblies of the tinners (called parliaments) were summoned by the warden under a writ from the Duke of Cornwall, for the regulation of the stannaries and redress of grievances: the last of them was held in 1752. The Stannary Courts are courts of record held by the warden and vice-warden, of the same limited and exclusive character as the Courts-palatine, in which the tinners have the privilege of suing and being sued. They were remodelled and regulated by acts 6 and 7 Will. IV. c. 106, 2 and 3 Vict. c. 58, and 18 and 19 Vict. c. 32. The last-mentioned statute provides, that from all the decrees and orders of the vice-warden on the common law side, there shall be an appeal to the Lord Warden, who is to be assisted by two assessors, members of the Judicial Committee of the Privy Council, or judges of the High Court of Chancery, or Court of Common Law at Westminster; and from the Lord Warden there is a final appeal to the Judicial Committee of the Privy Council.

In the county of Cornwall, the right to dig tin in unenclosed or 'wastrel' lands within specified bounds may be acquired by one who is not the owner of the lands, on going through certain formalities, the party acquiring this right being bound to pay one-fifteenth to the owner of the lands. An ancient privilege, by which the Duke of Cornwall had the right of pre-emption of tin throughout that county, has long fallen into abeyance; and certain duties to which he was entitled on the stamping or coinage of tin were abolished by 1 and 2 Vict. c. 120.

STA'NNIC ACID. See TIN.

STANOVOI', or STANOWOI KHREBET (Framework Mountains), an extensive mountain chain in Siberia, in the extreme north-east of Asia, forms the watershed between the rivers which flow north into the Arctic Ocean, and those which are tributary to the Amur. The chain extends in an east-north-east direction from the Transbaikal territory along the shores of the Sea of Okhotsk, separating into several branches, one of which stretches east to Behring's Strait. Of this great mountain chain, the length of which is estimated at 3000 miles, little is known further than that it is elevated and rugged, and that its peaks are covered with perpetual snow.

STA'NZA. See RHIME.

STAPE'LIA. See CARRION FLOWERS.

STAPHYLE'A AND STAPHYLEA'CEÆ. See BLADDER-NUT.

STAPHYLO'MA (from the corresponding Greek word, derived from *staphylē*, a bunch of grapes, or in this case, rather a grape at the end of a stalk) is a term employed by the oculist to signify any protrusion on the anterior surface of the eye. Staphyloma of the iris occurs when there is a protrusion of the iris through a perforation of the cornea, consequent either on ulceration or on a wound. Staphyloma of the cornea occurs when that coat of the eye is more or less completely destroyed, and when the cicatrix with which the iris has become covered is caused to protrude by the pressure of the fluids of the eye, in the form of an opaque white prominence. It is unnecessary to enter into details of the treatment of these affections, which must be left entirely to the hands of the surgeon.

STAPLE (A.-S. *stapel*, a prop, support; a heap, and hence a place where goods are stored up or exposed for sale), a term applied, in the commerce of the middle ages, in the first instance, to the towns in which the chief products of a country were sold, and afterwards to the merchandise that was sold at the staple towns. The staple towns, at first chosen from convenience, came in the course of time to be invested with important privileges. The staple merchandise of England has been enumerated as wool, wool-fells (i.e., sheepskins), leather, lead, and tin, to which have sometimes been added butter, cheese, and cloth. *Wool* was, however, in point of fact, a far more important article of export than any of the rest, and was really the subject of those multitudinous regulations which fixed the staple in particular towns, both of England and of the continent. Goods intended for exportation had, in the first instance, to be exposed for sale at the staple town; the principal purpose of this regulation being, probably, to restrict commerce to those places where the officers who collected the king's customs could superintend it. Another object kept in view in the provisions made in the 13th and 14th centuries with respect to the staple, was the encouragement of the resort of foreign merchants; indeed, greater privileges seem to have been accorded to the foreign than to the English merchants who attended the staple.

A tribunal of great antiquity, called the Court of the Staple, had cognizance of all questions which should arise between merchants, native or foreign. It was composed of an officer, called the Mayor of the Staple, re-elected yearly by the native and foreign merchants who attended the staple; two constables, appointed for life, also chosen by the merchants; a German and an Italian merchant; and six mediators between buyers and sellers, of whom two were English, two German, and two Lombard. The law administered was the *lex mercatoria*, and there was a provision that causes in which one party was a foreigner, should be tried by a jury one half of whom were foreigners. The most important legislative enactments regarding the Staple and the Court of Staple were the Statute of Acton Burnel (11 Edward I.), by which merchants were enabled to sell the chattels of their debtor, and attach his person for debt; 13 Edw. I. c. 3; and 27 Edw. III. c. 2, called the Statute of Staple, one object of which was to remove the staple formerly held at Calais to certain towns in England, Wales, and Ireland. With the growth of commerce the staples became more and more neglected, and at last fell altogether into disuse.

STAR, in Heraldry. The star is of frequent occurrence as a heraldic bearing; it sometimes represents the heavenly body so called, and sometimes the rowel of a spur. In the latter case, it is blazoned a *Mullet* (q. v.). Stars of more than five

Stars.

points should have the number of points designated, and the points may be wavy. A star, or *estoile*, with wavy points, is often designated a blazing star; and when the points are more than six in number, it is usual to represent only every second point as waved.

The star is a well-known ensign of knightly rank. A star of some specified form constitutes part of the insignia of every order of knighthood.

STAR, ORDER OF THE, an order of knighthood formerly existing in France, founded by John II. in 1350, in imitation of the then recently instituted order of the Garter in England. The ceremony of installation was originally performed on the festival

of the Epiphany and the name of the order is supposed to have been allusive to the Star of the Magi.

STARAI'A-RU'SSA, a town of Russia, on a tributary of Lake Ilmen, 184 miles south-south-east of St Petersburg. The town is remarkable for its salt springs, which attract many visitors in summer. The means of communication between St Petersburg and S., by the Moscow railway and the river Volkhov, are easy and rapid. Resident pop. upwards of 8700.

STAR ANISE. See ANISE.

STAR APPLE (*Chrysophyllum*), a genus of trees and shrubs of the natural order *Sapotaceæ*. The species are natives of tropical and sub-tropical countries. The S. A. of the West Indies (*C. Cainito*) is a shrub about eight or ten feet high. The fruit is large, rose-coloured, mixed with green and yellow; and has a soft sweet pulp of an agreeable flavour. Other species produce edible fruit.

STA'RBOARD. See LARBOARD.

STARCH, or **AMYLACEOUS MATTER** ($C_6H_{10}O_5$), is an organised substance of the class known as carbo-hydrates, which occurs in roundish or oval grains in the cellular tissue of certain parts of plants. It is very widely diffused through the vegetable kingdom, and is especially abundant in the seeds of the cereals, in the seeds of leguminous plants such as peas and beans, in the tuber of the potato, in the roots of arrowroot and tapioca, in the pith of the sago palm, &c. The grains of starch from the same kind of plant are tolerably uniform in size and shape, but vary in different species of plants from $\frac{1}{250}$th to less than $\frac{1}{3000}$th of an inch in diameter; and while some are circular or oval, others are angular: moreover, amongst other differences, some (chiefly the larger grains) exhibit a series of concentric rings, while in others no rings are apparent; and while the grains of potato-starch, if illuminated by polarised light, with a Nicol's prism placed between the object and the eye, present a well-marked black cross, in wheat-starch no such cross is perceptible.

Ordinary commercial starch occurs either as a white glistening powder, or in masses which are readily pulverised; and when pressed between the fingers it evolves a slight but peculiar sound. It is heavier than water, and is insoluble in cold water, alcohol, and ether. If, however, it be placed in water at a temperature of 150°, its granules swell from the absorption of fluid, and the mixture assumes a viscid, pasty consistence. Dilute acids rapidly induce a similar change, even without the agency of heat; and if heated with dilute sulphuric acid, the starch is first converted into dextrine, and finally into glycose or grape-sugar; and manufacturing chemists avail themselves of this property to obtain glycose on a large scale from starch. Starch dissolves in cold nitric acid, and on the addition of water to this solution, a white, tasteless, insoluble precipitate falls, which is known as *Xyloidin*, and explodes violently when struck by a hammer, or when heated up to about 350°. The composition of this substance is not positively known, but in all probability one or two equivalents of the hydrogen of the starch (most probably two) are replaced by a corresponding number of equivalents of peroxide of nitrogen (NO_2).

The reactions of starch with iodine and bromine are very remarkable. Iodine communicates to it a very beautiful purple colour, and hence starch-paste serves as a delicate test for free iodine. The purple colour which the iodine gives to the starch granules appears not to depend on a chemical combination, because on the application of heat the colour disappears, and reappears on cooling. Bromine communicates a brilliant orange tint to starch—a reaction by which the presence of free bromine may be readily detected. When heated to a temperature of from 340° to 400°, dry starch is converted into Dextrine (q. v.), or British gum. At a higher temperature, it undergoes decomposition, and yields on dry distillation the same products as sugar. When heated in steam under pressure, it also passes into dextrine, and finally into glycose. The addition of a little sulphuric acid hastens these changes.

During the germination of seed, the starch undergoes a kind of fermentation, and is converted into a mixture of dextrine and glycose. This change is due to the action of a peculiar ferment termed Diastase (q. v.), which exists in all germinating seeds during the process of growth, and is probably a mixture of albumen and gluten in a special stage of decomposition. Various animal matters, as, for example, saliva, pancreatic juice, the serum of the blood, bile, &c., exert the same action on starch as diastase. On treating starch with chlorine, a remarkable, colourless, oily fluid, *Chloral* (q. v.), is obtained. On prolonged exposure to the air, starch paste becomes acid, in consequence of the formation of lactic acid.

Starch is usually obtained by a simply mechanical separation of it from the other ingredients with which it is associated; advantage being taken of its insolubility in cold water. The details of the mode of separation vary according to the source from which it is procured. We extract from Miller's *Organic Chemistry* the method of procuring *potato-starch*: 'This variety is prepared on a large scale from potatoes, which contain about 20 per cent. of amylaceous matter. The cellular tissue of the tuber does not exceed 2 per cent. of the mass; whilst of the remainder about 76 per cent. consists of water, and the rest of small quantities of sugar, salts, and azotised matters. In order to extract the starch, the tubers are first freed from adhering earth by a thorough washing, and are then rasped by machinery. The pulp thus obtained is received upon a sieve, and is washed continuously by a gentle stream of water so long as the washings run through milky. This milkiness is due to the granules of starch which are held in suspension. The milky liquid is received into vats, in which the amylaceous matter is allowed to subside; the supernatant water is drawn off, and the deposit is repeatedly washed with fresh water until the washings are no longer coloured. The starch is then suspended in a small portion of water, run through a fine sieve to keep back any portions of sand, and after having been again allowed to settle, is drained in baskets lined with ticking; the mass is then placed upon a porous floor of half-baked tiles, and dried in a current of air, which is at first of the natural temperature; the drying is completed by the application of a moderate artificial heat' (pp. 100, 101). To obtain starch from wheat or rice, a more complicated process is required, as the large quantity of gluten which is associated with the starch in these grains requires to be removed either by fermentation, or, according to Jones's patent, by a weak alkaline solution, which dissolves the gluten, but does not affect the starch granules.

Commercially, there are two classes of starch—those used for food, and those used for manufacturing purposes. The former are treated under ARROW-ROOT (q. v.); the latter are chiefly made from wheat, rice, and potatoes; but in addition, large quantities of sago-starch are prepared in India and sent to Europe, and small quantities are from time to time prepared from other sources, such as the fruit of the horse-chestnut, &c.

The importance of starch becomes at once obvious when we consider that it may be regarded as the starting-point in the preparation of brandy and other forms of spirit, and of beer and porter, and that it enters largely into the great *saccharine* group, constituting one of the leading subdivisions of food. See DIGESTION. It is, moreover, largely employed as an article of domestic use for laundry purposes, and also in the manufacture of dextrine and grape-sugar.

We shall conclude with a few words on starch in its physiological and medical relations. It might have been inferred *a priori* that starch was an essential article of diet, from the fact of its abundant occurrence in edible vegetables, even if the fact had not been established by numerous physiological experiments. Thus various kinds of potatoes yield from 12 to 27 per cent. of starch; peas, 32½ per cent.; beans, 34 to 36 per cent.; wheaten bread, 53½ per cent.; wheaten flour, 56½ to 72 per cent.; oatmeal, 59 per cent.; ryemeal, 61 per cent.; barley-meal, 67 per cent.; maize, 81 per cent.; rice, 83 to 85 per cent.; and it occurs in even larger proportions in arrowroot, sago, and tapioca. In a state of health, the proper diet consists in the due admixture of the albuminous, saccharine (or starchy), oleaginous, and saline groups; but in certain forms of disease, an excess or a diminution of the starchy element is expedient. Thus, in cases of weak gastric digestion, it is not advisable to mix starchy food with the albuminous, as it soaks up the too scanty gastric juice without making any use of it. In such cases, moreover, articles of food like potatoes, new bread, pastry, &c., are apt to turn acid in the stomach, and check digestion. There are, again, some cases of gastric disorder in which a purely starchy diet is expedient. Thus, according to Dr Chambers, it is the best form of food 'during acute catarrhal bilious attacks at the commencement of treatment, in even chronic gastric cases, and whenever a dusky complexion, hypochondriasis, or general distress shew that arrested moulting has caused a collection in the body of effete tissues' (*Dietetics* in *Clinical Lectures*, 4th ed., p. 539). In the early stages of rheumatic fever and other acute diseases, it is usually expedient to limit the diet of the patient for a day or two to a purely starchy diet, such as arrowroot, tapioca, panado, &c. In returning from a purely starchy to a mixed diet, Dr Chambers suggests that such an arrangement shall be adopted as to prevent starchy and albuminous foods from being together in the stomach. For example, let the morning and evening diet be vegetable, with a mid-day meal of purely animal food. It should be recollected that although starch is converted into sugar by the saliva, pancreatic fluid, and intestinal juice (see DIGESTION), the change principally takes place from the action of the two last-named fluids in the small intestine. Hence, when the duodenum, jejunum, or ileum are morbidly affected, as in typhoid or enteric fever, in enteritis, in diarrhœa, &c., little or no starch should be given in the food.

Wheat-starch is the only variety of starch admitted into the Pharmacopœia. It is employed in medicine chiefly in the form of mucilage (prepared by triturating 120 grains of starch with 10 fluid ounces of distilled water gradually added, and boiling for a few minutes, constantly stirring). This preparation is used either alone or as a vehicle for more active agents, as an enema, in dysentery, diarrhœa, flatulent distention of the bowels, &c.; externally, it is used as an application to excoriations, to prevent bed-sores, &c., and as a basis for dusting-powders in various forms of discharging skin-diseases. Its use in Surgery for the construction of immovable bandages has been noticed in the article SPLINTS.

STAR-CHAMBER, a tribunal of considerable note in English history, which met in the old Council-chamber of the palace of Westminster, and is said to have its name from the circumstance that the roof of that apartment was decorated with gilt stars. It is generally supposed to have originated in early times out of the exercise of jurisdiction by the king's council, acting as the *concilium ordinarium* and not *privatum*. The powers of the council, however, had been abridged by several acts of Edward III., and had altogether greatly declined when act 3 Henry VII. c. 1, either revived and remodelled them, or instituted, according to the view taken by Mr Hallam, an entirely new tribunal. This statute conferred on the Chancellor, the Treasurer, and the Keeper of the Privy Seal, with the assistance of a bishop and a temporal Lord of the Council, and Chief-justices, or two other justices in their absence, a jurisdiction to punish, without a jury, the misdemeanours of sheriffs and juries, as well as riots and unlawful assemblies. Act 21 Henry VIII. c. 20, added to the other members of the court the President of the Council. Whether or not the above-cited act of Henry VII. meant to constitute a court distinct from the council, it is certain that, by the time of Elizabeth, the two jurisdictions were merged in one; and the resulting tribunal was, during the Tudor age, of undoubted utility as a means of bringing to justice great and powerful offenders who would otherwise have had it in their power to set the law at defiance. The civil jurisdiction of the Star-chamber, at that period, comprised controversies between English and foreign merchants, testamentary causes, disputes between the heads and commonalty of corporations, lay and ecclesiastical, and claims to deodands. As a criminal court, it could inflict any punishment short of death, and had cognizance of forgery, perjury, riots, maintenance, fraud, libels, conspiracy, misconduct of judges and others connected with the administration of the law, and all offences against the state, in so far as they could be brought under the denomination of contempts of the king's authority. Even treason, murder, and felony could be brought under the jurisdiction of the Star-chamber, where the king chose to remit the capital sentence. The form of proceeding was by written information and interrogatories, except when the accused person confessed, in which case the information and proceedings were oral; and out of this exception grew one of the most flagrant abuses of this tribunal in the later period of its history. Regardless of the existing rule, that the confession must be free and unconstrained, pressure of every kind, including torture, was used to procure acknowledgments of guilt; admissions of the most immaterial facts were construed into confessions; and fine, imprisonment and mutilation inflicted on a mere oral proceeding, without hearing the accused, by a court consisting of the immediate representatives of prerogative. The proceedings of the Star-chamber had always been viewed with distrust by the commons; but during the reign of Charles I., its excesses reached a height that made it absolutely odious to the country at large; and in the last parliament of that sovereign, a bill was carried in both Houses (16 Car. I. c. 10), which decreed its abolition.

STAR-FISH (*Asteriadæ*), a family of *Echinodermata* (q. v.), having in the centre of the body a stomach with only one aperture, but extending by two much-branched cæca, into each of the rays into

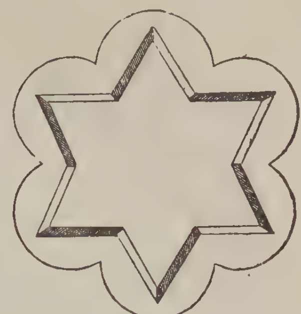
which the body is divided. In some, the central disc extends so as to include the rays, so that the general form is angular or lobed; in others, the disc is very small in comparison with the length of the rays. Locomotion is effected by very numerous Ambulacra (q. v.) placed in rows on the under side of the rays. A bony framework, of a vast number of pieces, extends to the extremity of each ray. The nervous system has its centre around the mouth, and sends a filament to each ray. Star-fishes are hermaphrodite, and produce vast numbers of eggs, which are retained for a time under the body of the parent, resting on the points of its rays at the bottom of the sea, and raising up the centre of the body, in order as it were to hatch them. The young are destitute of rays, and very unlike the mature form, so that their real nature was long mistaken. The mouth of star-fishes being on the under side, they seek their food—as indeed they perform all their motions—by crawling at the bottom of the sea, or on rocks, &c. They are very voracious, and

Star-fishes:

1, Common Cross-fish (*Uraster rubens*); 2, Gibbous Starlet (*Asterina gibbosa*); 3, Common Cross-fish, reproducing rays; 4, Eyed Cribella (*Cribella oculata*); 5, Lesser Sand-star (*Ophiura albida*).—From Forbes's *British Star-fishes.*

are troublesome to fishermen by devouring their bait. They possess, in a very high degree, the power of reproducing lost members; a disc with a single ray left will reproduce the other rays, and become a perfect star-fish. More extraordinary is the readiness which many of them display, particularly those with long and slender rays, in breaking off these members. Some species—BRITTLE STARS—can scarcely be procured for a museum in a tolerably perfect state, because they throw off ray after ray, and, in fact, break themselves to pieces upon any alarm. Star-fishes abound in the seas of all parts of the world. Almost no object is more familiar on the sea-coast of Britain than the COMMON S., CROSS-FISH, or FIVE FINGERS (*Asterias* or *Uraster rubens*), thrown up on the beach by the tide, or thrown out of fishing-boats in harbours. Some of the species are much larger; and some exhibit very beautiful colours; whilst others are interesting from their structure—the long serpent-like form of their rays, or the division of the rays by successive forkings, so that the whole creature is a globular mass, the surface of which is formed of a countless multitude of living tendrils.

STAR-FORT, in Field Fortification, is a strong work consisting of alternate salient and re-entering angles, arranged on a regular or irregular polygon. It is a common work for defending an eminence



Star-fort.

on a battle-field, or at the wing of a line, or as protection for the reserve-stores of an army.

STA'RGARD (Slav. *Starograd* or *Starigrod*, i. e., Old Town), a town of Prussia, province of Pomerania, is situated on the navigable river Ihna, 23 miles east-south-east of Stettin, with which, as with Posen and the whole east of Prussia, it is connected by railway. S. was formerly the capital of Lower Pomerania. It has various but not very important manufactures. Pop. 16,867. S. was raised to the rank of a town in 1129.

STAR JELLY. See NOSTOC.

STA'RLING (*Sturnus*), a Linnæan genus of birds, of the order *Insessores;* now the family *Sturnidæ*, nearly allied to *Corvidæ*, but in general of smaller size; the bill more slender and compressed, its point nail-like; the wings long and pointed. They are natives of almost all parts of the world, very generally gregarious, and some of them migratory. They feed on worms, insects, larvæ, and fruits. Some of them follow herds of quadrupeds, on account of the insects which attend them. The COMMON S. (*Sturnus vulgaris*) is a beautiful bird, rather smaller than the song-thrush or mavis, brown, finely glossed with black, with a pale tip to each feather, giving the bird a fine speckled appearance, particularly on the breast and shoulders; in advanced age it is more uniform in colour. The plumage of the female is less beautiful than that of

Starling (*Sturnus vulgaris*).

the male. Both sexes are more speckled in winter than in summer. The S. is abundant in most parts of Britain, and nowhere more so than in the

Hebrides and Orkneys. It is very abundant in the fenny districts of England. It is found in all parts of Europe, and throughout great part of Africa; and is also common in the north of Asia. Starlings make artless nests of slender twigs, roots, and dry grass, in hollow trees, in holes of cliffs, under eaves of houses, or, readily enough, in boxes, which are often placed for them in trees or elsewhere near houses. They unite in large flocks in autumn, and are readily known by their whirling mode of flight. The S. becomes very pert and familiar in confinement, displays great imitative powers, and learns to whistle tunes, and even to articulate words with great distinctness. Its natural song is soft and sweet.—The AMERICAN S., or MEADOW LARK (*S. Ludovicianus*), is larger than the Common Starling. It is common in the United States, migrating northwards in spring, and southwards in autumn, and congregating in great flocks in autumn and winter.

STARLINGS, in Architecture, are large piles driven in outside the foundations of the piers of bridges to break the force of the water and save the piers.

STAR-NOSE (*Condylura*, or *Astromyctes*), a genus of the Mole (q. v.) family, *Talpidæ*, having much general resemblance to moles, but with a longer tail, and an elongated slender muzzle, which bears at its extremity a remarkable structure of fleshy and somewhat cartilaginous rays disposed in a star-like form. The habits are very similar to those of moles. All the species of this genus are natives of North America. The best known is *Condylura cristata*, which inhabits Canada and the eastern parts of the United States.

STARODOU'B, a town of Little Russia, in the government of Tchernigov, and 100 miles north-east of the town of that name. It stands in the middle of a fertile district, but at a distance from any commercial highway. Pop. 12,474.

STAR OF BETHLEHEM (*Ornithogalum*), a genus of bulbous-rooted plants of the natural order *Liliaceæ*, nearly allied to Squills and Hyacinths.

Star of Bethlehem (*Ornithogalum umbellatum*).

The species are pretty numerous, natives almost exclusively of the eastern hemisphere, many of them of the Cape of Good Hope, and some of the south of Europe. The Common Star of Bethlehem (*O. umbellatum*), a native of France, Switzerland, Germany, the Levant, &c., is very common in flower-gardens. Its flowers are large, six to nine, in a corymbose raceme, white and somewhat fragrant. *Gagea lutea*, formerly *O. luteum*, with yellow flowers, is found in some parts of Britain in woods and pastures.

STAR OF INDIA, THE MOST EXALTED THE ORDER OF THE, an order of knighthood instituted by Queen Victoria in June 1861, with the view of affording the princes, chiefs, and people of the Indian Empire a testimony of her Majesty's regard, commemorating her Majesty's resolution to take on herself the government of India, and rendering honour to merit and loyalty. The order consists of

Star of India.

the Sovereign, a Grand-master, who is to be the Governor-general of India for the time being, and 25 knights, together with such extra and honorary knights as the crown may appoint. The members of the order are to be military, naval, and civil officers who have rendered important service to the Indian Empire, and such native chiefs and princes of India as have entitled themselves to her Majesty's favour. The insignia consist of a collar, badge, and star. The *collar* of the order is composed of the heraldic rose of England, two palm branches in saltire tied with a ribbon, and a lotus-flower alternating with each other, all of gold enamelled, and connected by a double golden chain. From an imperial crown, intervening between two lotus-leaves, depends the *badge*, consisting of a brilliant star of five points, and hanging from it an oval medallion, with an onyx cameo profile bust of Queen Victoria, encircled by the motto: 'Heaven's light our Guide,' in gold letters, on an enriched border of light-blue enamel. The *investment badge* is similar to the collar-badge, but with the star, the setting of the cameo, and the motto all of diamonds: it is worn pendent from a ribbon of pale blue with white borders. The *star* of the order is a five-pointed star or mullet of diamonds on an irradiated field of gold. Around it, on an azure fillet bordered with gold, is the same motto in diamonds, the whole encircled by wavy rays of gold.

STARS are distinguished from planets by remaining apparently immovable with respect to one another, and hence they were early called fixed stars, a name which they still retain, although their perfect fixity has been completely disproved in numerous cases, and is no longer believed in regard to any. Twinkling, or Scintillation (q. v.), is another mark which distinguishes stars from planets.

The first thing that strikes the observer is the apparent daily motions of the stars. The greater part appear to rise in the east, describe smaller or greater arcs in the heavens, and set in the west; while others describe complete circles round a point north of the zenith, that described by the so-called polar star being the smallest visible to the naked eye. These apparent motions arise from the rotation of the earth on its axis. Had the earth only this rotatory motion, the aspect of the starry heavens at any spot on the earth's surface would be the same at the same hour of the night all the year round; which is known not to be the case. In consequence of the earth's motion round the sun, or the apparent advance of the sun among the stars, the aspect of the heavens at a particular hour is always changing. The same position of the stars recurs four minutes earlier each night, and only at the same time after the lapse of a year.

With few exceptions, the *distance* of the fixed stars is still unknown, and must in all be enormously great. Since the time of Bradley, many attempts have been made to measure what is called the *yearly parallax* of the stars, and thus determine their distances. When we consider that the motion of the earth round the sun brings us at one time a whole diameter of its orbit (184 millions of miles) nearer to a particular region of the heavens than we were six months before, we should expect a change in the relative distances of the stars as seen from the two points—that as we approach them they should seem to separate. But no such change is seen to take place; and this was one of the early objections to the theory of Copernicus. The only answer that the Copernicans could give was, that the distance of the stars from us is so great that the diameter of the earth's orbit is as a point compared with it. The detection of the parallax of the fixed stars depended upon the perfection of instruments. The parallax of a star is the minute angle contained by two lines drawn from it, the one to the sun, the other to the earth. If that angle amounted to a second, the distance of the star would be 206,000 times that of the sun; and when the measurement of angles came to be reliable to a second, and still no parallax was discernible, astronomers could say that the distance of the nearest stars must be more than 206,000 times that of the sun—i. e., 206,000 times 92 millions of miles, or about 20 billions of miles. It is only since between 1832 and 1838 that anything like positive determinations of parallax have been made, chiefly by Henderson, Bessel, and Peters. The first published (Dec., 1838) was that of the double star 61 in the constellation of the Swan, by Bessel, who made the parallax 0″·37, giving a distance over 550,000 times that of the sun, or 52 billions of miles, so that the light of this star is about 8⅝ years in reaching the earth. The nearest of all the stars yet measured is *a Centauri*, the finest double star in the southern heavens, whose parallax was determined by Henderson and Maclear at the Cape of Good Hope to be 0″·9128 (the observations were made in 1832—1833; the result read before the Astronomical Society, Jan., 1839), or, as subsequently corrected, 0″·976, corresponding to a distance of about 20 billions of miles, and requiring 3⅛ years for its light to reach us. To Sirius, the brightest of the stars, a parallax of 0″·15, has been assigned, implying a distance six times that of *a* Centauri. 'It has been considered probable, from recondite investigations, that the average distance of a star of the *first* magnitude from the earth is 986,000 radii of our annual orbit, a distance which light would require 15½ years to traverse; and further, that the average distance of a star of the *sixth* magnitude (the smallest distinctly seen without a telescope) is 7,600,000 times the same unit—to traverse which, light, with its prodigious velocity, would occupy more than 120 years. If, then, the distances of the majority of stars visible to the naked eye are so enormously great, how are we to estimate our distance from those minute points of light discernible only in powerful telescopes? The conclusion is forced upon us that we do not see them as they appeared within a few years, or even during the lifetime of man, but with the rays which proceeded from them several thousands of years ago!'—Hind's *Astronomy*.

The stars have been divided into groups called Constellations (q. v.) from the earliest times. The several stars belonging to the same constellation are distinguished from one another by Greek letters, beginning the alphabet with the brightest; and when these are not sufficient, by Roman letters and by numbers. Many of the most brilliant stars have special names. They are also divided according to their brightness into stars of the first, second, third, &c., magnitudes—a division which is necessarily somewhat arbitrary. The smallest stars discernible by a naked eye of ordinary power are usually called stars of the fifth magnitude; but an unusually sharp eye can discern those of the sixth and even seventh magnitude. All below are *telescopic* stars, which are divided in a very undetermined way down to the twentieth magnitude. Sir J. Herschel has determined that the light of Sirius, the brightest of all the stars, is 324 times that of a mean star of the sixth magnitude. By processes of photometric observation and reasoning, it is concluded that the intrinsic splendour of α Centauri is more than twice that of our sun, and that of Sirius 394 times. Among stars of the first magnitude in the northern hemisphere are usually reckoned Aldebaran (in Taurus), Arcturus (in Bootes), Atair (in Aquila), Betelgeux (in Orion), Capella (in Auriga), Procyon (in Canis Minor), Regulus (in Leo), Vega (in Lyra). In the southern hemisphere are Achernes (in Eridanus), Antares (in Scorpio), Canopus (in Argo), Rigel (in Orion), Sirius (in Canis Major), Spica (in Virgo), and α Centauri and α Crucis that have no special names.

No apparent magnitude, in the proper sense of the word, has yet been observed in any star. In the best and most powerfully magnifying telescopes, even the brightest stars of the first magnitude appear, not with small discs as all the planets do, but as luminous points without any visible diameter, and always the smaller the better the telescope. We are therefore totally ignorant of the real size of the fixed stars; nor could it be determined though we were sure of their distances, for the apparent diameter is an essential element in the calculation. We cannot, then, say whether the greater brilliancy of one star, when compared with another, arises from its greater nearness, its greater size, or the greater intensity of its light, or from several of these causes together. It is, however, conjectured with reason that the fixed stars in general are not less than our sun, and that many, as Sirius, are much larger. It may be considered certain that none of the fixed stars shine with borrowed light; all are self-luminous.

The *number* of the stars is beyond determination. Those visible by the naked eye amount only to a few thousands. Stars of the first magnitude are usually reckoned at 15—20, of the second at 50—60, of the third about 200, of the fourth at 400—500, of the fifth at 1100—1200. But in the following classes, the numbers increase rapidly, so that stars of the sixth and seventh class amount to above 12,000. Stars are most dense in that region of the heavens called the Milky Way, which is

mostly composed of stars of the eleventh and twelfth magnitudes. W. Herschel observed 116,000 stars pass the field of his telescope in a quarter of an hour, while directed to the densest part of the Milky Way.

That the fixed stars are not really immovable, as their name would imply, is seen in the phenomenon of *Double* or *Multiple Stars*, which are systems of two or more stars that revolve about one another, or rather about their common centre of gravity. As they can be seen separate only by means of a telescope, and in most cases require a very powerful one, their discovery was possible only after the telescope was invented. Galileo himself discovered their existence, and proposed to make use of them in determining the yearly parallax of the fixed stars. After a long lapse of time, Bradley, Maskelyne, and Mayer again directed attention to the phenomena of double stars; but nothing important was made out respecting them till the elder Herschel made them the subject of a protracted series of observations, which led to the most remarkable conclusions as to their nature. The united observations of Struve, Savary, Encke, South, and especially those of Herschel the younger, continued for four years in the southern hemisphere at the Cape of Good Hope, have raised the number of observed double, or rather multiple, stars to more than 6000, of which the greater part are binary, or composed of two, but many are triple, some quadruple, and a few even quintuple, or consisting of five stars. The distance between the stars composing these systems is always apparently small (varying from less than 1″ up to 32″); but apparent nearness does not always constitute a double star, for two really distant stars are not unfrequently so nearly in the same line, as seen from the earth, that they appear to be close together. In real multiple stars, the individuals are not only comparatively near to one another, but they revolve around one another. Among stars of the first three magnitudes, every sixth is a multiple star; among the smaller stars, the proportion is much less. In some cases, one of the stars is much larger than the other, as in the star Rigel in Orion, and in the polar star; but oftener the connected stars are nearly equal in luminous power. The two members of double stars are mostly of one colour, but a difference of colour is observed in about one-fifth of the whole number. In many of these cases, the one colour is the complement of the other, and it is possible that the colour of the smaller star may be subjective, arising from the action of the other upon the eye.

It was in 1803, after 20 years' observation, that Sir W. Herschel advanced the view, which has been more and more confirmed since, that double stars are connected systems of two or more stellar bodies, revolving in regular orbits around one another, or rather round their common centre of gravity. Their motions are found to follow the same laws as prevail in the solar system, and the orbits are elliptical. These distant bodies are therefore subject to the Newtonian law of gravitation. The period of revolution has, in several cases, been roughly approximated; among the shortest is that of ζ Herculis, estimated at 30 years; others are set down at hundreds. In cases where the parallax is known, the size of the orbits can be determined; and thus the astronomer is able to assert in regard to the double star 61 Cygni that the orbit described by these two stars about each other undoubtedly greatly exceeds in dimensions that described by Neptune about the sun. Even the masses of these stars have been calculated as being together 0·353, that of our sun being 1. It is a consequence of these revolutions that many stars are now seen double that formerly seemed single, and *vice versâ*. If the plane of revolution have its edge presented to the earth, the stars will seem to move in a straight line, and at times to cover one another. The star ζ Herculis, seen by Herschel double in 1781, appeared single in 1802, and was first seen double again by Struve in 1826. The figure represents the relative positions of

Fig. 1.

the two stars composing γ in Virgo, at different times since the earliest observations. The period of revolution is presumed to be 182 years.

The *proper motion* of stars, discovered by Halley, is of another kind. It consists in a displacement in various directions of the individual stars, so that the configuration of constellations is slowly changing. 'The Southern Cross,' says Humboldt, 'will not always shine in the heavens exactly in its present form; for the four stars of which it consists move with unequal velocity in different paths. How many thousand years will elapse before its total dissolution cannot be calculated.' The proper motions yet observed vary from $\frac{1}{20}$th of a second to 7″·7. According to Bessel, the proper motion of the binary star 61 Cygni amounts to 5″·123, so that in 360 years it would pass over a space equal to the moon's diameter. It must thus take thousands of years to alter sensibly the aspect of the heavens; although, taking into account the enormous distances, the actual velocities must be great. Of 3000 stars observed by Bessel, 425 had a perceptible motion. Argelander has recently published a list of 560 stars having a proper motion.

It was first observed by Sir W. Herschel that there is a perceptible tendency in the stars generally to diverge or open up in one quarter of the heavens, and to draw together in the opposite quarter; and this he attributed to a proper motion of our sun with his planets in the direction of the former point. The apparent motion thus caused is complicated with the real independent motions of individual stars. The point towards which this motion is directed, which is called the 'solar apex,' was fixed by Herschel in the constellation Hercules; and the result of subsequent and independent researches gives a nearly coincident point. The velocity has been calculated at upwards of 150 millions of miles a year, or 17,600 miles an hour—i. e., rather more than one-fourth of the earth's velocity in its orbit.

The stars have not a uniform colour. This, as has been noticed, is the case with many of the double stars; but many single stars have a decided tint. 'Insulated stars of a red colour, almost as deep as that of blood, occur in many parts of the heavens; but no green or blue star (of any decided hue) has, we believe, ever been noticed unassociated with a companion brighter than itself.'—*Herschel.*

The relative brightness of stars appears to have altered. Of the two fine stars Castor and Pollux in Gemini, Castor was at one time the brightest, but now comes after Pollux; Aldebaran seems to have decreased, Atair (in Aquila) to have increased.

More striking than these gradual and not very well marked changes are the periodic alterations exhibited by several stars, hence called *variable* stars. A considerable number have been observed, of which the most remarkable are Mira (the 'wonderful') in Cetus, and Algol in Perseus. The first attains its greatest lustre every 334 days, and appears for 14 days as a star of the second, and even at times of the first magnitude; it then decreases for two or three months, till it becomes of the sixth and even tenth magnitude, so as to be for half a year invisible to the naked eye and usually to telescopes. After this it begins again to increase, but more rapidly than it decreased. It is visible to the naked eye for three or four months of its period. Of all the variable stars yet observed in Perseus, Algol has the shortest period, being 68 hours 49 minutes. It appears for about 60 hours a star of the second magnitude, then decreases for four hours, and appears for a quarter of an hour of the fourth magnitude, after which it increases again for four hours. Various explanations have been offered of these mysterious appearances; the stars are supposed to turn on their axes, and to have their surfaces unequally luminous in different places; or a large dark body is assumed to be revolving about the luminous one, so as to intercept more or less of its light in different positions; or the stars are lens-shaped, &c. There is nothing, however, inadmissible in the supposition that the intensity of the light itself may vary; and if in other suns, why not in our own?

Allied to the variable stars are the *new* or temporary stars that appear suddenly in great splendour, and then disappear without leaving a trace. A number of instances are on record. It is not impossible that these also may be periodic.

Star Systems.—From the appearances connected with the Milky Way or Galaxy (q. v.), Sir W. Herschel came to the conclusion that the stars forming our firmament do not extend indefinitely into space, but are limited in all directions, the mass having a definite shape. He conceived the shape to be something like that of a huge millstone, having one side cleft, and the two laminæ set apart at a small angle. Let the diagram (fig. 2) represent a vertical section of such a broad flat stratum, and suppose the solar system situated as at S, to a spectator looking on either side, in the direction of the thickness, as SB, the stars would appear comparatively sparse, but all round in the direction of the breadth (as SA) there would appear a dense ring, which would separate

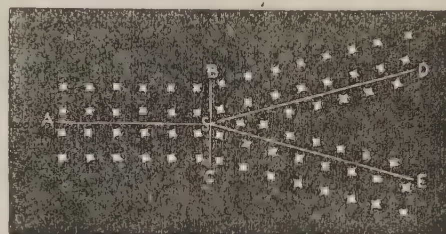


Fig. 2.

into two branches (SE, SD) in the direction of the cleft side. This supposition accounts for the appearance of the Milky Way, and all subsequent observations have tended to confirm the conjecture. Situated as we are within the system, we cannot hope ever to attain more than a rude notion regarding it; to get a definite outline we must be placed without it (see NEBULÆ).

But this star system, which we may call our own, as our sun belongs to it, is but an item in the stellar universe. The appearances known as nebulæ, for the most part at least, are believed to be similar agglomerations of suns, separated from our system and from one another by unfathomable starless intervals. Their forms are very various, but in general pretty well defined, and not without symmetry. The aspect of some of them is even

Fig. 3.

startling. A few specimens are given in the woodcut (fig. 3).

STAR-THISTLE. See CENTAUREA.

START POINT (A.-S. *steort*, a tail or promontory), a rocky headland in the south of Devonshire, with a lighthouse 204 feet above the sea, in lat. 50° 13′ 4″ N., and long. 3° 38′ W.

STARVA'TION, or INANI'TION, are terms applied to the phenomena resulting from an entire deficiency, or an insufficient supply of food. From M. Chossat's well-known experimental investigations of this subject (*Recherches Expérimentales sur l'Inanition*, Paris, 1843), it appears that the average loss of weight in mammals and birds, between the commencement of fasting and the death of the animal, was 40 per cent., the loss varying above and below 40 per cent. in the different organs and tissues, as shewn in the following table:

PARTS WHICH LOSE MORE THAN FORTY PER CENT.		PARTS WHICH LOSE LESS THAN FORTY PER CENT.	
Fat, ...	93·3	Muscular coat of Stomach,	39·7
Blood, ...	75·0	Pharynx and Œsophagus,	34·2
Spleen, . . .	71·4	Skin, ...	33·3
Pancreas, . . .	64·1	Kidneys, . . .	31·9
Liver, . .	52·0	Lungs, ...	22·2
Head, . . .	44·8	Bones, . . .	16·7
Intestines, . . .	42·4	Eyes, ...	16·0
Muscles of Locomotion,	42·3	Nervous System, .	1·9

Hence it appears that there is an almost complete removal of the fat, and a great reduction of the blood, while the nervous system is scarcely affected; and hence it would seem as if the supervention of death was coincident with the consumption of all the combustible materials of the body, and that previously the remaining nutritive force was concentrated on the nervous system.

The following are amongst the most prominent phenomena which Chossat observed either during the experiments or after the death of the animals: 1. Dropsical effusions. 2. Softening and destruction of the mucous membrane. 3. Blackening of the viscera, especially of the liver. 4. Bluish, livid, yellow, and reddish stains during life in the transparent parts of the skin. 5. Hectic fever, and a continuous decrease in the power of the body to resist cold. 6. At first a scanty excretion of dry, bilious, grass-green fæces, and afterwards diarrhœa of liquid saline matter. 7. Convulsions similar to those in death by hæmorrhage. 8. Death by starvation seems to be in reality death by cold; since the temperature of the body is not much diminished until the fat is nearly consumed, when it rapidly falls, unless it be kept up by heat applied externally. 9. Young animals succumbed far sooner than adults. 10. The results of insufficient food were in the end the same as those of total deprivation; the total amount of loss being almost the same, but the rate being less, so that a longer time was required to produce it.

Chossat did not find that much influence was exerted on the duration of life by permitting or withdrawing the supply of water; but there is no doubt that in man, and probably in mammals generally, death supervenes much earlier when liquids as well as solid food are withheld. For a full account of the symptoms of starvation as they occur in the human subject, we must refer the reader to the writings on hygiene and forensic medicine of Orfila, Rostan, Caspar, Taylor, &c.; and especially to Dr Donovan's account of the Irish famine of 1847, in the *Dublin Medical Press*, Feb. 1848, p. 67. The following are the most striking symptoms: In the first place, pain is felt in the stomach, which is relieved on pressure. The countenance becomes pale and cadaverous; the eyes are wild and glistening; the breath hot, the mouth parched, and the saliva thick and scanty. An intolerable thirst supervenes, which, if there be no access to water, becomes the most distressing symptom. The body becomes gradually emaciated, and begins to exhale a peculiar fœtor, while the skin becomes covered with a brownish dirty-looking and offensive secretion almost as indelible as varnish, which Donovan at first mistook for encrusted filth. The bodily strength rapidly declines; the sufferer totters in walking, like a drunken man; his voice becomes weak and whining, and he is ready to burst into tears on the slightest occasion. In the cases recorded by Donovan, imbecility, and sometimes almost complete idiocy, ensued, but in no instance was there delirium or mania, which has been described as a symptom of starvation in cases of shipwreck. On examination after death, the condition of the body is such as might be expected from Chossat's experiments, viz., extreme general emaciation; loss of size and weight of the principal viscera; almost complete bloodlessness, except in the brain; and the gall-bladder distended with bile, which tinges the neighbouring parts. Moreover, decomposition rapidly ensues.

It is impossible to fix the exact time during which life can be supported under entire abstinence from food or drink. Dr Sloan has given an account of a healthy man, aged 65, who was found alive after having been shut up in a coal mine for 23 days, during the first ten of which he was able to procure a small quantity of foul water. He was in a state of extreme exhaustion, and notwithstanding that he was carefully nursed, he died three days after his rescue. Dr Willan records the case of a young gentleman who, under the influence of religious delusion, starved himself to death. He survived for sixty days, during which time he took nothing but a little orange juice. In this case, life was probably abnormally prolonged in consequence of the peculiar emotional excitement of the patient. Judging from the cases of abstinence owing to disease of the throat and impossibility of swallowing, Dr Taylor infers 'that in a healthy person under perfect abstinence, death would not commonly take place in a shorter period than a week or ten days.'

It is worthy of notice that a deficient supply of food seems to check the elimination and removal of the effete materials of the body. This fact accounts not only for the tendency to putrescence, which is exhibited during the process of starvation, and for the rapidity with which putrefaction ensues after death, but for the pestilential diseases which almost always follow a severe famine; the excess of disintegrated matter in the blood rendering the system especially prone to the reception and multiplication of the diseases characterised as zymotic, such as fever, cholera, &c.

Statant.

STA'TANT, in Heraldry, a term applied to an animal standing still, with all the feet touching the ground. If the face be turned to the spectator, it is said to be *statant gardant*, or in the case of a stag, *at gaze*.

STA'TEMENT, in Scotch Law, is sometimes used technically to denote the account given before the sheriff by a person when arrested as a criminal. It is called the prisoner's declaration in England.

STATEN ISLAND, S. AM. See SUPP. in Vol. X.

STA'TEN ISLAND, a beautiful and picturesque island, which forms the western shore of the bay and narrows, and the southern shore of the harbour of New York. It contains 58½ sq. m., forming the county of Richmond, divided into five townships. Its shores are dotted with villages, and its heights crowned with villas. A narrow sound, the Kill van Kull, separates it from New Jersey. Four strong forts guard, with those on the opposite shores of Long Island, the entrance to the harbour, and the Hudson and East Rivers. It is also the site of a Seaman's Retreat, and Sailor's Snug Harbour, asylums for sick disabled seamen. Population in 1860, 25,493; in 1870, 33,029; in 1880, 38,994.

STATES, or ESTATES, in Politics, the name given to the classes of the population who either directly or by their representatives take part in the government of a country. In all European countries where the northern conquerors established themselves, the rudiments of representative government appeared in the form of assemblies brought together to deliberate with the sovereign on the common weal. These assemblies at first consisted of the two estates of the clergy and the nobility or baronage, who together constituted the whole free population of the realm; the nobility including not merely the greater barons, but the whole freeholders. As the burgesses gradually emancipated themselves, and rose into importance, they formed a third estate. In France, we find the *tiers état*, or citizens recognised in the States-general (q. v.) in 1302. In

Scotland, the earliest occasion on which the burghs are mentioned as attending and concurring in a grant of taxation, is in the Parliament held at Cambuskenneth in 1326, in which Robert Bruce set forth to the assembled estates the diminished condition of the royal income in consequence of the protracted struggle through which the country had come. The burgesses, represented by the commissioners for the burghs, continued in Scotland to be a separate estate, and were not, as in England, amalgamated with the knights and lesser barons, who, in the Scots parliament, were always classed with the baronage. The lesser barons were, however, first allowed, and latterly enjoined, to appear by representatives; and the three estates of clergy, barons, and burgesses all sat and deliberated in one house. In England, on the other hand, the knights and lesser barons were at an early period separated from the greater barons, and conjoined with the burgesses into the third estate, which occupied a separate chamber from the Lords Spiritual and Temporal. This peculiarity in the original constitution of the *tiers état* of England necessarily gave it a weight which it did not possess elsewhere, and exercised an important influence on the constitutional history of the country. As the peasants became emancipated, we also find them in some countries taking a share in the legislative power, either as a part of the *tiers état*, or, as in Sweden, forming a fourth estate. The four estates of nobles, clergy, citizens, and peasants are still recognised in Sweden; and in the Swedish legislature, as at present constituted, each has its separate chamber. Throughout Europe, except in Russia, Turkey, and some of the smallest German principalities, there are constitutional assemblies recognising more or less the co-operation of the estates with the sovereign in the legislative power. Some of these assemblies have but one chamber, but more of them have two. The lower chamber is always wholly, or partly, elective, but sometimes consists of separate delegates from the different orders of the community, as in Saxony, where there are representatives of landed proprietors, of towns, of peasants, and of traders and manufacture. The upper house, or senate, is in some constitutions hereditary: in some it consists of members named by the sovereign, or by the nobility, or some other class of the community, and often it combines these elements. In a few instances, as in the Netherlands and Brazil, it is elected by the same constituency as the lower house, and differs only in the higher property qualification required of its members.

STATES-GENERAL (Fr. *états généraux*), the name which was given to the convocation of the representative body of the three orders of the French kingdom; so named in contradistinction from the *états provinciaux*, or assemblies of the provinces. As far back as the time of Charlemagne, there were assemblies of clergy and nobles held twice a year to deliberate on matters of public importance; and in these assemblies the extensive body of laws bearing the name of the Capitularies of Charlemagne was enacted. The succeeding centuries, however, were adverse to free institutions; and these national convocations, becoming gradually less important, seem to have ceased to be held about 70 years after Charlemagne's death. From that time forward, there is no trace of any national assembly in France till 1302, when the *états généraux*, including the three orders of clergy nobles, and citizens, were convened by Philippe le Bel, with the view of giving greater weight to the course adopted by the king in his quarrel with Pope Boniface VIII. In 1314, we find the States-general granting a subsidy: during the reigns of Philippe IV. and his successor, the imposition of taxes by arbitrary authority was the subject of general discontent; and in 1355, the states were strong enough to compel the government to revoke the taxes so imposed. The States-general, however, though their consent seems in strictness to have been considered requisite for any measure imposing a general taxation, had, unlike the assemblies under the Carlovingian kings, no right of redressing abuses except by petition, and no legislative power. Under Charles VI. and Charles VII. the States-general were rarely convened, and it was often found more convenient to ask supplies from the provincial states. But as the royal authority increased, the formality of any convention of states general or provincial gradually ceased to be regarded as indispensable, and a final and unsuccessful struggle for immunity from taxation took place at the States-general of Tours in 1484. Louis XIII. convoked the States-general, after a long interval, in 1614, but dismissed them for looking too closely into the finances; and from that time down to the Revolution, the crown, with the tacit acquiescence of the people, exercised the exclusive powers of taxation and government. In 1789, the memorable convention of the States-general took place, which ushered in the Revolution. As soon as they had assembled, a dispute arose between the two privileged orders and the third estate as to whether they should sit and vote in one chamber or separately. The *tiers état*, of its own authority, with such deputies of the clergy as chose to join them—none of the nobles accepting their invitation—assumed the title of the *Assemblée Nationale*, a name by which the States-general had previously been sometimes designated. See ASSEMBLY, NATIONAL.

The name States-general is also applied to the now existing legislative body of the kingdom of the Netherlands (q. v.). It is so called in contradistinction from the provincial states, which are legislative and administrative assemblies for the several provinces.

STA'TICÉ, a genus of plants of the natural order *Plumbagineæ*, having a funnel-shaped, membranaceous, and plaited corolla; the flowers in spikes on one side of a panicled, leafless, flowering stem (*scape*). Several species are natives of Britain, growing near the sea, most of them on muddy shores and in salt marshes. The root of *S. Caroliniana*, called Marsh Rosemary, is used in North America for all the purposes of kino and catechu, and is a very powerful astringent.

Staticé Limonium.

STA'TICS (Gr. root *sta*, to stand), the science of the equilibrium or balancing of forces on a body or system of bodies, has gradually advanced from the days of Archimedes to the vast developments it has now acquired. Singularly enough, though most of its simpler theorems are

very generally known, are almost popular, in fact, there is no science in which elementary teaching is so defective. The ordinary proofs of its fundamental principles, such as the *Parallelogram of Forces*, the *Principle of the Lever*, &c., are usually founded on the supposition that a body in equilibrium is *absolutely at rest*. Now, any one who knows that the earth rotates about its axis, that it revolves about the sun, that the sun is in motion relatively to the so-called fixed stars; that *they* are, in all probability, in motion about something else which is itself in motion, &c., will at once see that there is no such thing as absolute rest, and that *relative rest* or motion, unchanged with reference to surrounding bodies, is all that we mean by equilibrium. He will then, at once, see that the foundations of statics are to be sought in the LAWS OF MOTION (q. v.). And, in fact, Newton's Second Law of Motion gives us the necessary and sufficient conditions of equilibrium of a single particle under the action of any forces; while his Third Law, with the annexed Scholium, gives these conditions for any body or system of bodies whatever.

The simplest statement of the conditions of equilibrium of a rigid body which can be given, is that furnished by this Scholium of Newton's, which is now known by the name of the Principle of Energy (see FORCE) or Work (q. v.). It is as follows: A rigid body is in equilibrium if, and is not in equilibrium unless, in *any* small displacement whatever, no work is done on the whole by the forces to which it is subject. In the case of what are called the *Mechanical Powers* (q. v.), this is equivalent to the statement, that work expended on a machine is wholly given back by the machine—or that the work done by the *power* is equal to the work spent in overcoming the *resistance*.

It is shewn in the geometrical science of Kinematics that any motion whatever of a rigid body can be reduced to *three* displacements in any three rectangular directions, together with *three* rotations about any three rectangular axes—so that the equilibrium of a rigid body is secured if no work be done on the whole in any of these *six* displacements. There are thus six conditions of equilibrium for a rigid body under the action of any forces—and these are reduced to *three* (two displacements and one rotation), if the forces are confined to one plane; and to *one* (a displacement), if the forces act all in one line.

Equilibrium may be *stable*, *unstable*, or *neutral*. It is said to be stable, if the body, when slightly displaced in any way from its position of equilibrium, and left free, tends to *return* to that position. It is unstable, if there is any displacement possible, which will leave the body in a position in which it tends to *fall further away* from its position of equilibrium. It is neutral, if the body, when displaced, is still in equilibrium. It is easily shewn, but we cannot spare space for the proof, that a position of stable equilibrium is, in general, that in which the Potential Energy (see FORCE) of the body is a minimum—of unstable equilibrium, where it is a maximum (for some one direction of displacement at least)—of neutral equilibrium, where the potential energy remains unchanged by any small displacement. Thus, a perfect sphere, of uniform material, is in neutral equilibrium on a horizontal plane—while an oblate spheroid, with its axis of rotation vertical, is in stable equilibrium; and a prolate spheroid, with its axis vertical, is in unstable equilibrium on the plane. Similar statements hold for other than rigid bodies. Thus, a chain, or a mass of fluid, is in stable equilibrium when its potential energy is least, i. e., when its centre of gravity is as low as possible. This simple statement is sufficient for the mathematical solution of either question.

STA'TIONERY, a very general term applied to the materials connected with writing, such as paper, books for accounts, drawing, &c., envelopes, sealing materials; and even writing-desks, blotting-books, albums, porte-feuilles, pocket-books, red tape, and many other necessaries of the writing-desk, are included.

STATIONERY OFFICE, an office in London established by the Lords of the Treasury in 1786, for the purpose of purchasing, wholesale, writing materials for the supply of the government offices at home and abroad. It also contracts for the printing of all Reports and other matters laid before the House of Commons. The duties are performed by a comptroller, a storekeeper, and about thirty clerks or other subordinate officers. There is a branch establishment in Dublin. The appointments are made by the Lords of the Treasury.

STATIONS (Lat. *statio*), a name applied in the Roman Catholic Church to certain places reputed of special sanctity, which are appointed to be visited as places of prayer. The name is particularly applied in this sense to certain churches in the city of Rome, which, from an early period, have been appointed as churches which the faithful are particularly invited to visit on stated days. The names of these churches are found on the several days in the Roman missal prefixed to the liturgy peculiar to the day. The word, however, is employed in a still more remarkable manner in reference to a very popular and widely-received devotional practice of the Roman Catholic Church, known as that of 'The Stations of the Cross.' This devotion prevails in all Catholic countries; and the traveller often recognises it even at a distance by the emblems which are employed in directing its observance—the lofty 'Calvary' crowning some distant eminence, with a series of fresco-pictures or bas-reliefs arranged at intervals along the line of approach. These representations, the subjects of which are supplied by scenes from the several stages of the Passion of our Lord, are called Stations of the Cross, and the whole series is popularly known as the *Via Calvaria*, or Way of Calvary. The origin of this devotional exercise, like that of local pilgrimages, is traceable to the difficulty of access to the Holy Places of Palestine, consequent on the Turkish occupation of Jerusalem and the Holy Land; these representations being designed to serve as some analogous incentive to the piety and faith of the Christian worshipper of our Lord in his Passion. The number of the so-called 'stations' is commonly 14, although in some places 15, and in others, as Vienna, only 11; but whatever may be their number, the subject of all is a sort of pictorial narrative of the Passion. The devotional exercise itself is performed by kneeling at the several stations in succession, and reciting certain prayers at each. Forms of prayer are prescribed to those who can read. The poor and ignorant recite the Lord's Prayer and Hail, Mary! all being directed to fix their thoughts in grateful memory upon 'the sufferings which each representation describes our Lord as having undergone, in atonement for the sins of mankind.' Many 'indulgences' are granted to those who, having duly repented of their sins, shall piously perform this exercise. Many of these stations are celebrated as works of art, especially one near Bologna. Some of those in the Alps and along the precipitous banks of the Rhine, Danube, and other German rivers, are exceedingly striking and picturesque.

STATI'STICS, that branch of Political Science which has for its object the collecting and arranging of facts bearing on the condition, social, moral, and material, of a people. The word statistics was first employed in the middle of last century by Professor Achenwall of Göttingen, who may be considered the founder of the science. The principle lying at its foundation is, that the laws which govern nature, and more especially those which govern the moral and physical condition of mankind, are constant, and are to be discovered by the investigation and comparison of phenomena extending over a very large number of instances. Accidental diversities tend to neutralise each other, their influence diminishing as the area of investigation increases; and if that area be sufficiently extended, they so nearly disappear, that we are entitled to disregard them altogether. While the length of a single life cannot be counted on, an average of 1000 or 10,000 lives gives us a constant quantity, sufficiently near the truth to answer the purposes of insurance companies. Even the acts which are the most purely voluntary as regards individual men, have been found to be subject to laws which, in respect of the masses which make up society, are invariable in like circumstances, and discoverable.

The science of statistics has a twofold relation to political and social economy. The facts collected by the statist are the bases on which political economy rests; their application to social and economical problems is an appeal from imagination to fact. But the statist must be guided by the political economist in what direction to extend his investigations: without political economy, we should have had no statistics.

It would be difficult to give any exhaustive enumeration of the multifarious topics which may be the subject of statistical inquiries. The results of statistics have been classified as—1. Problems regarding the nature of wealth and its production and growth in a community; 2. Problems relating to inland and foreign trade; 3. Problems relating to taxation and finance; 4. Problems regarding currency, banks, and prices; 5. Problems relating to the wages and hire of labour, and the division of employments; and 6. Problems relating to the functions of the state as regards interference with the economic relations of its subjects.

The Statistical section added to the British Association for the Advancement of Science in 1833, and the London Statistical Society founded in 1834, have made some valuable contributions to this science, and helped to diffuse a knowledge of its principles and its importance. But while in some branches there is undoubtedly room for the labours of individuals or associations, statistics are, generally speaking, more appropriately the province of the state. The most important of the subjects with which this science is cognizant, cannot be investigated without unrestricted access to government offices, and authority to demand information; and the ordinary administration of government is continually affording opportunities for the collection of the most valuable statistical facts. For some time past, statistics have largely occupied the attention of the more enlightened governments of Europe. The statistical reports issued by the various departments of the French government deserve especial praise for the comprehensiveness of their basis, and the clearness of their arrangement. The government of Belgium has, since 1841, engaged with much diligence in statistics, and Austria and Prussia have also their Statistical departments. In the United Kingdom, a department of the Board of Trade has, since 1832, been charged with collecting and publishing detailed and classified information obtained from various departments of government regarding the revenues, population, commerce, wealth, and moral and economical condition of the country and colonies, as well as a selection from the statistics of foreign countries. Every session of parliament, there are also numerous statistical returns called for, which no doubt sometimes contain valuable material, but being drawn up to suit the particular purpose of those who move for them they have too often a desultory, fragmentary character, and from the absence of any general plan, are of little use but for the moment. It has been suggested that, by establishing a separate Statistical department of government, we might, at a hardly greater cost, obtain a yearly *résumé* of administrative statistics complete enough to supersede, to a large extent, the present system of moving for returns whenever they are wanted.

The frequent connection of statistics with political theories renders it important to guard against premature statistical conclusions, of which two very fertile sources are calculations from an insufficient number of data, and neglect to make allowance for disturbing causes.

STA'TUARY AND STATUE. See SCULPTURE.

STA'TUTE OF FRAUDS, in English Law, is a statute which required certain contracts and agreements to be in writing, in order to be binding in such cases. The object of the statute, 29 Char. II. c. 3, was to prevent the perjury which so frequently takes place where the proof of the contract is left to the memory of the parties. All leases for more than three years, and their assignments, must be in writing; and no freehold estate in lands can be created except by writing. So promises and agreements to bind an executor or administrator personally must be in writing; as well as to bind one party for the debt of another. So as to contracts made for the sale of land, or of interests in land; and for the sale of goods above £10 in price, unless part of the goods have been accepted and received, or partly paid for.

STATUTE OF LIMITATIONS. See LIMITATION.

STATUTES OF DISTRIBUTIONS. See DISTRIBUTIONS.

STATUTES, or ACTS OF PARLIAMENT, are those laws made from time to time by the legislature, which qualify and alter the common law or previous statutes. All laws may be divided into common law and statutory law, the former being unwritten, the latter being written. The theory as to the common law is, that it consists merely of ancient statutes, worn out by time, of which the written exposition has perished, but which tradition has kept alive; and much of the common law necessarily consists of what has sometimes been called judge-made law — a department of law which has often been ignorantly denounced as illegal or unconstitutional, but which is a necessary part of every code, under whatever name it is disguised. The legislature of Great Britain consists of the Queen, Lords, and Commons, in parliament assembled, and the statutes which they pass have been likened by Sir Matthew Hale to written contracts or indentures, the general public being bound, by their respective agents, as if by solemn deed. There is no legal mode of altering the previously existing law, except by a statute passed with the consent of parliament; but there are other ways of modifying the law, so far as mere details of administration are concerned —as, for example, by orders in council, by ordinances by charters, and by by-laws issued under some

inherent or statutory power belonging to corporations. The mode in which a statute is made belongs properly to the head of Procedure in Parliament. Statutes or acts of parliament are all founded on the theory that the legislature has an inherent right to alter all previous laws or statutes; and though sometimes great and leading statutes have been declared to be unalterable by any future parliament, this restriction is obviously utterly futile, and inconsistent with the idea of a legislature. Statutes are usually divided, according to the number of persons affected by them, into public and private—the former applying to the whole public, the latter only to the persons named or described. There is also a subdivision of both into local and personal statutes. Statutes are also divided into declaratory, penal, or remedial, according to the nature of their object. There are certain important rules as to the interpretation of statutes, the chief business of the various courts of law and equity being to construe or interpret the statutes. A statute begins to operate from the time when it receives the royal assent, unless it state some other time for its commencement; but formerly each statute was presumed to take effect from the beginning of the session of parliament in which it passed, until the rule was changed, in 1793, by the act 33 Geo. III. c. 13. The leading rule in construing statutes is, that the words are to be taken in their ordinary grammatical sense, unless the context shews that they are used in some other sense. All other rules resolve more or less into this. There is also a well-known rule that penal statutes are to be construed less strictly than other statutes of a remedial kind. Another rule is, that a subsequent statute repeals one that is prior, either expressly or by necessary implication, if the prior one is inconsistent in substance. Though it might seem an easy task to construe or interpret what is meant by a statute, it is in practice so far from being easy, that it requires a special training and long experience to arrive at an accurate mode of construction, the chief business of lawyers being to acquire this art; and one excels another solely or chiefly by virtue of the tact, skill, and accuracy of thinking which are required to do such work in perfection. All the main disputes in litigation turn chiefly on the different interpretations put by parties on statutes or contracts, both of which are construed according to precisely the same rules. Another rule applicable to statutes is, that each remains in force until it is repealed, either expressly or impliedly. So much confusion, however, has arisen out of the multiplicity of statutes, and it is so difficult for lawyers to discover what statutes have been so impliedly repealed, that, of late years, a process of revision and examination has been instituted by the government with a view to repeal expressly all that is obsolete and that is already only impliedly repealed, so as to reduce the bulk of the statutes, which have now grown to an inconvenient size. This task is preliminary to a codification of those statutes which remain after such revision and expurgation.

STAUBBACH, FALL OF, a celebrated waterfall in the southern part of the canton of Bern, Switzerland, a mile from the village of Lauterbrunnen, and 8 miles south of Interlachen. It is one of the loftiest in Europe, having a descent of between 800 and 900 feet, but it often disappoints visitors, who expect a swift loud-roaring cataract, and find instead a slender stream of water, concealing the face of the precipice like a 'beautiful lace veil, and imitating in its centre the folds of the drapery.' Long before it reaches the bottom, it is blown into a dust of silver spray, whence its name *Staubbach* (Dust-stream). Both Byron and Wordsworth have praised it in verse.

STAU'NTON, a town, capital of Augusta co., Virginia, on the Chesapeake and Ohio Railroad, and on a branch of the Shenandoah River, 120 miles west-north-west of Richmond; is the site of the Western State Lunatic Asylum and of Deaf and Dumb and Blind Asylums. It contains 10 churches, 2 newspapers, 4 academies and seminaries, mills, foundries, and manufactories. Pop. (1870) 5120; (1880) 6664.

STAVANGER. See SUPPLEMENT in Vol. X.

STA'VESACRE. See LARKSPUR.

STAVRO'POL, a government in the south-east of Russia, bounded on the N. by the government of Astrakhan, and by the country of the Don Cossacks; by the Caspian Sea on the E.; and by the Caucasus on the S. Area, 28,800 sq. m.; pop. (1865) 359,172. The chief rivers are the Kuban and Terek, forming the greater part of the southern boundary, and the Kuma. Along the shores of the Caspian, there are no harbours, and only fishermen's boats can approach the beach. The climate is milder in the east than in the west. In the south-west, where the soil is fertile, and produces millet and wheat, agriculture is the chief employment; in the north-east, the inhabitants lead a nomad life. Vineyards line the banks of the Terek and Kuma, and mulberry trees are cultivated for the rearing of silk-worms. Immense herds of oxen and sheep are sent to the interior of Russia.

STAVROPOL, capital of the government, stands on the chief highway from Europe to the Caucasus, 200 miles south-east of Rostov. It was founded in the end of the last century, and as yet it is only important from its position. Pop 5261.

STAY, STAYSAIL. See RIGGING, SAIL.

STEALING. See LARCENY.

STEAM. Steam is water in the gaseous form (see HEAT). When dry, it is invisible and transparent, like air, and is not to be confounded with *vapour*, which is steam returned to the state of water, and thus become visible — water-dust, as it were. As steam has become the most important of all motive powers, the properties on which its action depends deserve careful consideration. If we suppose the piston, *pp* (fig. 1), to have been close at the bottom of the cylinder, and then drawn up to its present position, the space *a* below it is a vacuum, and the piston has to be held up against the whole pressure of the atmosphere, which is equal to 15 lbs. on the square inch. If, now, a little water could be introduced into the bottom of the cylinder, without admitting any air, a quantity of vapour would rise from it, and press with more or less force on the lower side of the piston, so as to sustain a portion of the weight of the atmosphere. How much vapour would rise, and how much elastic force or pressure it would exert, would depend upon the temperature of the water and cylinder.

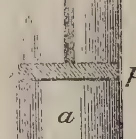

Fig. 1.

It is found that the vapour that rises at a low temperature has little elastic force. At 32°, the vapour in the space *a* would only sustain ·2 inch of mercury (see BAROMETER), corresponding to a pressure of $\frac{1}{10}$th of a pound on the square inch; if the apparatus were heated to 80°, more vapour would rise, until the tension or force would sustain 1 inch of mercury, shewing a pressure of ½ lb. on the square

inch. This would relieve part of the pressure of the external air on the piston, just as a portion of rarefied air would do. But there is this difference between vapour and air: if the space *a* were occupied by rarefied air, by lowering the piston, and compressing it into less space, its elastic force would increase, until it became equal to that of the external air, or greater. Not so with vapour; for if the piston were made to descend on it, instead of being compressed and made stronger, a portion of it would be condensed into water, and what remained would have the same force as before. This is on the supposition that the temperature remains the same; by raising the temperature of vapour sufficiently, it may be made to sustain any amount of compression, and acquire any degree of force.

The force of the vapour in *a* increases rapidly, as more and more heat is applied. At 100°, its pressure is equal to 1·86 inch of mercury; at 180°, it is 15 inches, or half the pressure of the atmosphere; so that if the piston is sustained by a hand, the hand will now feel itself relieved of half its load. When at last the heat comes to 212°, the pressure of the vapour is 30 inches of mercury, or 15 lbs. on the square inch, and at this point the piston would be sustained without a hand, the pressures on its two sides being equal.

It is at 212° that water in an open vessel begins to boil; that is, the vapour rises rapidly and in volumes, being able to displace the atmosphere (see BOILING). In this state, it is usually called *steam;* but there is no essential difference between steam at 212° and steam at 60°. The steam rising from boiling water in an open vessel is of the same temperature as the water—viz., 212°; but while passing into steam, it is found to absorb a great quantity of heat which does not affect the thermometer, and is therefore called *latent* heat (see HEAT).

When a cubic inch of water is converted into steam at the ordinary pressure of the atmosphere, its volume is increased to 1600 or 1700 cubic inches—that is, a cubic inch of water becomes nearly a cubic foot of steam. If produced under a pressure of two atmospheres, the steam of an inch of water will occupy only half the space, and so of other pressures.

When water is boiled in an open vessel, neither the temperature of the water, nor that of the steam rising from it, ever rises higher than 212°, however hot the fire; the heat as it enters is carried off in a latent state in the steam. But under pressure, the temperature of both can be raised to any degree. If, when the water and steam in *a*, fig. 1, came to 212°, the application of heat were still continued, more steam would continue to rise, and the pressure on the under side of the piston being now greater than that of the air above it, the piston would begin to ascend; but, suppose it held in the same position by force, the upward pressure of the steam would be found rapidly to increase, until it would soon require a weight of 15 lbs. on the square inch to keep it down; shewing that the elastic force of the steam was now equal to twice that of the atmosphere, or to 30 lbs. on the square inch. If at this point the temperature of the water and steam were examined, it would be found to be 250°.

Fig. 2 represents an apparatus which shews the elastic force of steam raised at higher temperatures than 212°. A strong copper sphere has in the bottom of it a quantity of mercury *m*, and above that a quantity of water *w*. A strong glass tube, open at both ends, passes air-tight into the sphere, with its lower end dipping into the mercury, and has a scale of inches EF, attached outside. T is a thermometer, with its bulb inside the sphere; and *b* is a tube opening into the sphere, with a stop-cock that may be opened and shut at pleasure.

The stop-cock *b* being open, let heat be applied to the bottom of the vessel until the water boils. The rising steam will soon expel the air, and occupy its place, being equal to it in elastic force. Before the application of heat, the mercury within the tube *t* does not rise above the level of the rest at *o*, for the tube differs from a common barometer in being

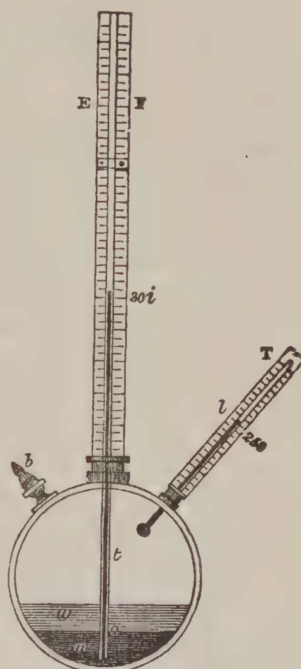

Fig. 2.

open at top; nor does it rise even when the water boils, for while *b* is open, the steam has no more pressure on the surfaces of the water and mercury than the air had. But if *b* is now shut, the pressure on the surface of the mercury within the sphere increases, and the mercury within the tube begins to rise and appear without the vessel. When it has risen to the point marked 30 inches on the scale (counted from *o*, the level of the surface within the vessel), it shews that the elasticity of the steam is able to sustain a column of mercury of 30 inches over and above the pressure of the atmosphere, which is resting on the top of that column, and is equal to another column of 30 inches. Its force is therefore equal to 60 inches of mercury, or 30 lbs. on the square inch; which is shortly expressed by saying, that it has a pressure of two atmospheres. A further rise of 30 inches in the tube would indicate an additional pressure of 15 lbs., or of three atmospheres in all.

Along with the mercury in the barometer tube, the thermometer also rises, but by no means at an equal rate. When the water boils, it has mounted to 212°, and it continues steadily at that point so long as the tube *b* is open; but on shutting *b*, it immediately begins to rise; and when the barometer tube is at 30 inches, the thermometer is found at about 250°. An addition of 38° of heat has thus doubled the elastic force of the steam. Another addition of 38° to the temperature would not simply

add another atmosphere to the pressure, but a great deal more; as will be seen from the following table:

Temperature, Fahrenheit.	Pressure in Atmospheres	Pressure in Pounds on the Square Inch.
212°	1	15
250°	2	30
275°	3	45
290°	4	60
372°	12	180
432°	20	300

The extreme danger of continuing to apply heat to a vessel while the steam is not allowed to escape, is thus evident; the bursting force soon becomes such as no vessel can resist.

Steam, like air and other gases, follows what is known as 'the law of Mariotte' (q. v.); its elastic force is always inversely as the space into which it is compressed. If the steam-space in the vessel fig. 2 is a cubic foot, it contains, at 212°, the steam of a cubic inch of water; when the temperature comes to 250°, another cubic inch of water has risen in steam, and has thus compressed the former quantity into one-half the space, but at the same time made its elastic force twice as great. If a cubic foot of this compressed steam is allowed to escape into a vessel of two cubic feet, its elastic force immediately falls from two to one atmosphere.

It is necessary here to bear in mind what was explained above with regard to vapour at low temperatures; viz., that steam cannot exist at a certain tension or pressure, if it is below a certain temperature. If a vessel were filled with steam from the apparatus fig. 2 while at the temperature 250°, and pressure of 30 lbs. to the square inch; as it cooled, portions of it would be condensed into water, and the pressure would diminish, until, at 212° of temperature, the pressure would be only 15 lbs. This fact in the constitution of steam causes a considerable loss of steam-power, through the cooling of the pipes and cylinders of engines.

Another fact regarding the constitution of steam deserves attention, from its importance in point of economy. We should naturally expect that it would take more heat or fuel to convert a pound of water into steam at 250° or 290° than at 212°; in reality, however, the difference is very slight; and the circumstance is thus explained. Steam rising from water at a low temperature, absorbs more latent heat than it does at a higher temperature. Thus, steam rising at 212°, absorbs about 1000° of latent heat; at 312°, it absorbs only 900°. Now, supposing the water put into the boiler at 60°, in the former case, 152° of heat have to be supplied to it to make the water boil, and then 1000° in the shape of latent heat—sum 1152°; in the latter, 252° are supplied to bring the water to boiling, and 900° to convert it into steam—sum, as before, 1152°. The expenditure of fuel is thus the same in both. Careful experiments have shewn that the sum of the latent and sensible heats is somewhat greater at the higher temperatures; but for practical purposes the law may be held true as above stated.

STEAM-CARRIAGE. Very early in the history of steam-locomotion, projects were formed for running steam-carriages on common roads—not to draw a train of vehicles after them, but each carriage to have passenger-accommodation as well as steam-power. Robison suggested such a thing to Watt so far back as 1759. A French inventor, Cugnot, tried a steam-carriage at Paris in 1770, which went with so much force as to dash down a brick wall, and thereby deter other inventors. In 1782, Murdoch exhibited a model of a steam-carriage; in 1784, Watt described his plans for another; and in 1786, Symington produced a model of a third. In the last-named year, too, Oliver Evans announced certain projects of the kind in the United States. In 1802, Messrs Trevethick and Vivian patented a steam-carriage, planned on a much better principle, than any that had preceded it; they adopted high-pressure steam, of which previous inventors had been afraid. The carriage was tried, but the ingenious patentees received very little encouragement, and soon turned their attention to railway matters. A long interval then passed without any new inventions in this kind of road-locomotion. When Telford and other engineers had improved the roads and highways, inventors were again induced to apply steam-power as a substitute for horse-power to road-vehicles. Bramah made a steam-carriage, in 1821, on a plan patented by Julius Griffiths. Gordon invented one in 1822, which worked something like a squirrel in a cage, the engine being within a cylinder which rolled along the ground; and another in 1824, which appeared to walk upon six iron legs. Goldsworthy, Gurney, Burstall, Hill, James, Hancock, Summers, Ogle, Heaton, Church, Dance, Field, Squire, Maceroni, Scott Russell, Hills, Sir James Anderson—all invented new forms of steam-carriage between 1824 and 1841. Some of these displayed great ingenuity, and attained a speed of 10 or 12 miles an hour on common turnpike roads. Sir Charles Dance ran such a carriage between Gloucester and Cheltenham in 1831, doing the 9 miles in 55 minutes; but the opposition of local interests put him down, after he had made 400 such trips without an accident, and carried a very large number of passengers. In the same year, Mr Hancock began running his steam-carriage, called *The Infant*, regularly between London and Stratford; and some time afterwards, Mr Scott Russell ran *his* invention between Glasgow and Paisley. All these three were passenger-vehicles which plied for traffic on the road. In the very numerous inventions from time to time brought forward, the passengers were in some cases seated in front of the engine and boiler; in others, they were seated behind; in others, the tank for water was placed beneath the passengers' feet; while in a fourth kind there was a passenger-carriage, distinct from, but linked to, the steam-locomotive. None of the inventions, however, attained to commercial success, so many were the difficulties which beset them.

The last quarter of a century has exhibited inventions rather for heavy traction than for passenger steam-carriages. One of the most remarkable of the latter kind is that which the Earl of Caithness drove, in 1864, from Inverness to his seat near Thurso. It carried three or four persons, and ascended and descended very steep inclines without much variation of speed. As a question of profit or commercial advantage, the inventors of such engines now look to their employment on common roads, for dragging ponderous weights which would otherwise require a long team of horses. Numerous patents have been taken out with this view, by Boydell, Bray, Clayton, Burrell, Giles, Stirling, Aveling, Cresswell, and other inventors, for carriages of strong construction, and generally with broad wheels. In one invention, the wheels cog themselves in a very ingenious way, to enable them to grip the ground in ascending gradients; in another, the wheels carry a sort of plank railway with them, to lay down as they roll over soft marshy ground. Some of these heavy traction-engines have been employed in drawing ponderous masses in the dockyards, in the yards of great engineering establishments, and in the roads and streets of the metropolis; while many have been sent out to Asia and South America, to draw heavy loads in regions where roads are scarce and defective, or where steep ascents would tax the strength of

draught-animals, or where ordinary narrow-wheel vehicles would sink into soft ground.

Acts of parliament were passed in 1861 and 1865 to regulate the use of locomotives on common roads. The width, the weight, the speed, the number of attendants, the toll, the consumption of smoke, the lights, the signals, the hours—are all so determined by clauses in these acts (especially the second) as to discourage rather than encourage enterprises of this kind. This restrictive legislation had its cause in the fear that accidents would otherwise be prevalent. See also STEAM-C. in SUPP. in Vol. X.

STEAM-CRANE. See SUPPLEMENT in Vol. X.

STEAM-ENGINE. By a steam-engine is now generally understood an engine in which the elasticity or expansive force of steam is used as the moving-power; just as the weight or impulse of water is in the water-wheel, or the pressure of the wind in a windmill. In some of the earlier engines of this kind, it was really the pressure of the atmosphere that was the motive-power, steam being employed merely as a means of producing a vacuum through its rapid condensation, and thus allowing the pressure of the atmosphere to come into play. As a source of power, steam has many advantages over wind and water. It is independent of the weather, may be applied anywhere, affords a constant equable motion, and is capable of indefinite increase. Its invention, therefore, has caused a new era in the arts; and the revolution which it has brought about in industry of all kinds, as well as the influence it has had on civilisation in general, and must yet have in a higher degree, are altogether incalculable.

The invention of steam as a moving-power is claimed by various nations; but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to the English and the Americans. It would appear that as early as 1543, a Spanish captain, named Blasco de Garay, shewed in the harbour of Barcelona a steamboat of his own invention. It is most likely that Blasco's engine was on the principle of the Æolipile of Hero, invented 130 B.C., in which steam produces rotatory motion by issuing from orifices, as water does in Barker's Mill (q. v.). The preacher Mathesius, in his sermon to miners (Nuremberg, 1562), prays for a man who 'raises water by fire and air,' shewing the early application of steam-power in Germany; and the German engineer, Sol. de Caus, in the service of the Elector Palatine in Heidelberg, describes, in his work, *Les Raisons des Forces Mouvantes avec Diverses Machines* (Frankf. 1615), a steam-machine, which was merely a contrivance for forcing the water contained in a copper ball through a tube by applying heat. The Italian engineer, G. Branca, invented, in 1629, a sort of steam windmill; the steam being generated in a boiler, was directed by a spout against the flat vanes of a wheel, which was thus set in motion.

In England, among the first notices we have of the idea of employing steam as a propelling force, is that contained in a small volume,* published in 1647, entitled *The Art of Gunnery*, by Nat. Nye, mathematician; in which he proposes to 'charge a piece of ordnance without gunpowder,' by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breech 'till it burst out suddenly.' But the first successful effort was that of the Marquis of Worcester. In his *Century of Inventions*, the manuscript of which dates from 1655, he describes a steam-apparatus by which he raised a column of water to the height of 40 feet. This, with the exception of Blasco's, was the first really useful application of steam; the others had been mere toys. Sir Samuel Morland, in 1683, submitted to Louis XIV. a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent for the application of steam-power to various kinds of machines was taken out in 1698 by Captain Savery. In 1699, he exhibited before the Royal Society a working model of his invention. Savery, in pumping mines, made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel. Papin, who had been made acquainted, through Leibnitz, with the attempts of Savery, but who must be allowed at the same time the honour of an original inventor, gave, in 1707, a complete theory of the steam-engine, together with a drawing of an engine of his own construction, having as early as 1688 and 1690 published precursory ideas on the subject. Some attribute to Papin the origin of the idea of the cylinder and piston; but this is denied by others. Thomas Newcomen, a blacksmith, carried out the principle of the piston in his Atmospheric Engine, for which he took out a patent in 1705. This was the first engine that was made practically and extensively useful, and forms the transition to the present steam-engine. It was chiefly used for

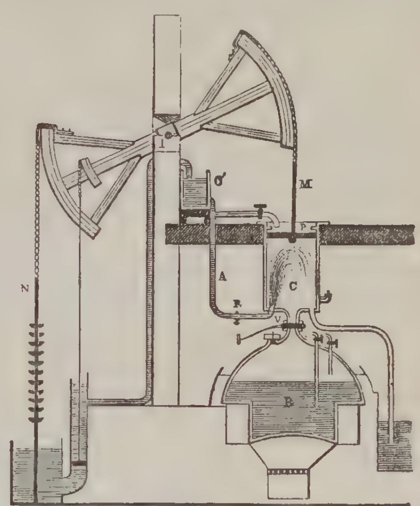

Fig. 1.

working pumps. To one end of a beam moving on an axis I, was attached the rod N, of the pump to be worked; to the other, the rod M, of a piston P, moving in a cylinder C, below. The cylinder was placed over a boiler B, and was connected with it by a pipe provided with a stop-cock V, to cut off or admit the steam. Suppose the pump-rod depressed, and the piston raised to the top of the cylinder—which was effected by weights suspended at the pump-end of the beam—the steam-cock was then turned to cut off the steam, and a dash of cold water was thrown into the cylinder by turning a cock R, on a water-pipe A, connected with a cistern C′. This condensed the steam in the cylinder, and caused a vacuum below the piston, which was then forced down by the pressure of the atmosphere, bringing with it the end of the beam to which it was attached, and raising the other along with the

* The volume is in the possession of Mr S. Holliday, to whom we are indebted for this fact.

pump-rod. The cock was then turned to admit fresh steam below the piston, which was raised by the counterpoise; and thus the motion began anew. The opening and shutting of the cocks was at first performed by an attendant, but subsequently by levers acted on by pins in a rod suspended from the beam, so that the machine became self-acting. Newcomen's was thus really an atmospheric engine, in accordance with its name. Engines of this description were found in practice to raise 7 or 8 lbs. for every square inch of piston.

The next essential improvements on the steam-engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam, necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great, that only about one-fourth of what was admitted into the cylinder was actually available as motive-power. Watt therefore provided a separate vessel in which to condense the steam, and which could be kept constantly in a state of vacuum without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and forms the foundation of his great fame. He made many other improvements in the details of steam-engines, the most beautiful of which is the *parallel motion;* and in conjunction with his partner, Boulton, he so improved the quality of the workmanship employed in constructing steam-engines, that he was able to introduce the double-acting engine, in which the cylinder is closed at both top and bottom: the piston is connected to the beam by a piston-rod, which passes through a *stuffing-box.* In this form of engine, steam was admitted by suitable valves, worked by the engine itself, alternately at the top and bottom of the cylinder, pushing the piston up and down with a force in proportion to the pressure of the steam; and at the same time a communication was regularly opened by valves between the cylinder and separate condensing vessel, so that the steam, after having pushed the piston from one end of the cylinder to the other, suddenly rushed into the condensing vessel, where it met and mingled with a stream of cold water, and was instantly condensed, thus leaving in the cylinder a vacuum as perfect as in the condensing vessel itself, and that without cooling the cylinder to any important extent. This form of engine, introduced by Boulton and Watt in 1769—1785, is essentially the same as the condensing engine now in general use.

It would be inconsistent with our limits to enter into the constructive details of steam-engines; we can only afford to give a general notion of the way in which the motion is originated, and to explain the chief principles on which the motive-power and economy of engines depend. Steam-engines are of two kinds, *condensing* and *non-condensing.* The non-condensing engine being the more simple of the two, may be first considered.

The Non-condensing Engine.—If steam with a tension of two atmospheres is admitted above a piston, and a communication is opened between the steam below it and the atmosphere, the pressure on the two sides of the piston will differ by an atmosphere, the piston will descend, and the steam will rush out into the atmosphere with the same force that the atmosphere rushes into a vacuum. In other words, the atmosphere is a vacuum to high-pressure steam, and enables the condenser to be dispensed with. Hence the name of Non-condensing Engine. Non-condensing engines alone are used in

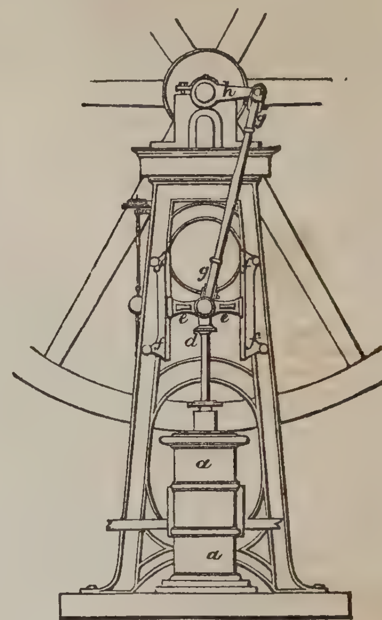

Fig. 2.

locomotives, and wherever economy of space is important. Fig. 2 represents a front view of the form known as the *crank-overhead* engine; fig. 3 is a section of the cylinder and valve-chest. The *cylinder, aa,* is made of cast-iron, and bored in a lathe; the *piston, vv,* is made to ply up and down in it, air or steam tight; and the *piston-rod, d,* passes through a hole in the cylinder cover and a *stuffing-box* above it, in which it is surrounded by packing of hemp and tallow, so as to prevent the escape of steam. From near the top and bottom of the cylinder proceed two passages, which open outwards near each other into a cavity *bb,* called the valve-chest. Between the two openings or

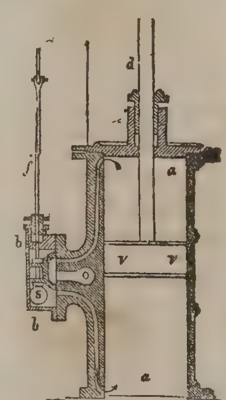

Fig. 3.

steam-ports that lead to the interior of the cylinder, there is another opening or port *o,* which does not enter the cylinder, but leads to the exhaust-pipe, by which the steam escapes when it has done its work. The surface or facing where these three ports open is made smooth, so that the valve, which is a hollow metal plate, may slide upon it steam-tight. Fig. 4 shews the three steam-ports, on a larger scale, with the valve *a* in two positions; in the one, it connects the upper duct *cc* with the exhaust-pipe *b*; in the

other, the lower duct d' is connected with b'. The cavity behind the valve in the valve-chest bb, fig. 3, is always filled with steam, which enters from the boiler by the steam-pipe s.

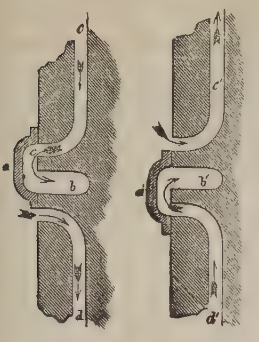

Fig. 4.

When the valve covers the upper port, the lower is left open to the steam-chest, so that steam rushes into the cylinder below the piston, and presses it up, while the steam which is above the piston escapes by the exhaust b (or o in fig. 3). By the time the piston has reached the top, the valve has commenced its descent towards the position a', fig. 4, and the motion of the piston is reversed. The valve is made to slide up and down at the right time by the motion of the shaft through means of an eccentric and rod j. The alternating motion of the piston-rod d is converted into the rotatory motion of the shaft by means of the Crank (q. v.) h, and connecting-rod gg.

Another form of engine now in general use is the horizontal engine, represented in fig. 5. It differs in no respect in its action from that just described, but it is more cheaply made, and can be driven at a higher velocity in consequence of its more compact form, and more secure attachment to its foundations.

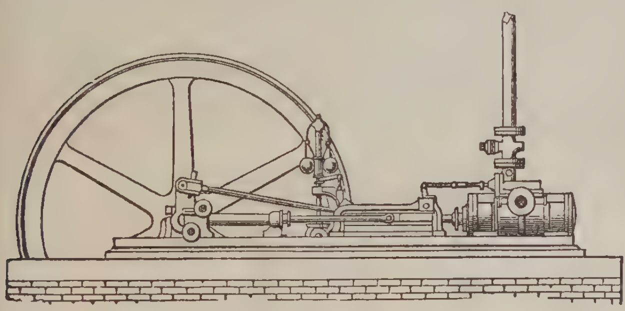

Fig. 5.

The amount of working-power in a steam-engine depends on the tension or pressure of the steam, the size of the piston, and the rate at which it travels. Suppose that the area of the piston vv, fig. 3, is 1000 square inches; that the pressure of the steam entering the cylinder is 3 atmospheres, or 45 lbs. on the square inch; that the length of a *stroke*, that is, an ascent or a descent of the piston, is 5 feet; and that 20 strokes (10 up and 10 down, corresponding to 10 revolutions of the crank and shaft) are made in the minute. While the piston is ascending, the steam above it is open to the atmosphere through the waste-pipe, and therefore its pressure is equal to that of the atmosphere, or 15 lbs. to the inch; and the pressure below the piston being 45 lbs., it moves under a pressure equal to the difference, or 30 lbs. to the inch; which, for the whole surface, gives a force of 30,000 lbs. Now, a pressure of 30,000 lbs. over 5 feet, makes $30{,}000 \times 5$ or 150,000 units of work for one stroke; and $150{,}000 \times 20 = 3{,}000{,}000$ will be the work done in one minute. Dividing this by 33,000, the units of work in a horse-power, we get 90·9 (91 nearly) as the theoretical horse-power of such an engine.

The steam in the cylinder has always less pressure than that in the boiler, partly from being cooled, and partly from being obstructed by the comparative narrowness of the passages on its way. The pressure is also unequal at different parts of the stroke, owing to the opening and closing of the ports being only gradual. In calculations of work, then, a certain mean pressure has to be taken as the multiplier. In addition to this, allowance has to be made for losses by friction—the friction of the piston, of the piston-rod and its cross-head ee (fig. 2), of the connecting-rod gg, of the shaft in its bearings, of the eccentric and its rod j, of the feed-pump, &c. On an average, from $\frac{1}{4}$ to $\frac{1}{3}$ of the calculated power of an engine has to be deducted for these losses, in order to get the effective power.

Steam used Expansively.—A great saving of steam arises from working it expansively. Suppose that the steam enters below the piston, fig. 6, at a pressure of 4 atmospheres, or 60 lbs. to the square inch. Set off $ba = 4 \times 15 = 60$, to represent the amount of the pressure, and complete the parallelogram bf, f being the highest point to which the bottom of the piston reaches; af thus represents the length of a stroke, which we shall suppose to be 5 feet. Were there no pressure on the upper side, and did the pressure below continue uniformly 60 lbs. to the top, the work due to 1 square inch of the piston for each stroke of 5 feet, would be $60 \times 5 = 300$; and this may be represented by the rectangle $abef$, the area of which is found by multiplying ba by af. But the piston is resisted all the way by a force of 15 lbs. to the inch, or 1 atmosphere; and if ak is made $\frac{1}{4}$ of ab, the figure $akif$ will represent the deduction to be made on this account; so that the work really due to a square inch of the piston is represented by the rectangle $kbei$, or $45 \times 5 = 225$.

But instead of allowing the steam to flow into the cylinder during the whole time of the stroke, let it be cut off when the piston is at c, or one-half the stroke; the steam already in the cylinder will expand and follow the piston, still urging it on, although with a diminishing force. When the piston has reached the top, the steam will have expanded to twice its former bulk, and by the law of Mariotte (q. v.), its pressure will be reduced to half of what it was, or 2 atmospheres, which will be expressed by fl, taken equal $\frac{1}{2}$ fe, or

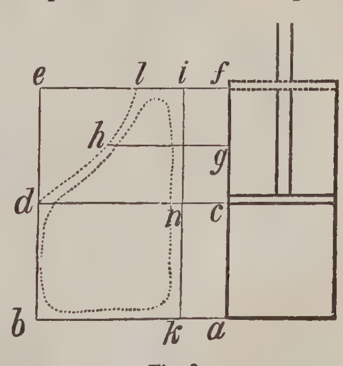

Fig. 6.

30. At any intermediate point, as g, the line gh representing the pressure is found by this proportion, $ga : ca :: cd$ (or ab) $: gh$; that is, the pressures are inversely as the spaces occupied by the steam. If, for example, $ga = 3\frac{3}{4}$ feet, and $ca = 2\frac{1}{2}$ feet, the proportion will be $3\frac{3}{4} : 2\frac{1}{2}$, or $15 : 10 :: 60 : 40 = gh$.

When a number of pressure lines or ordinates are thus found, a line *dhl* traced through their extremities forms a curve (part of a hyperbola); and the area of the figure *ndhli* will represent the work done on a square inch of the piston after the steam is cut off, still allowing for the resistance on the other side of the piston, which remains constant to the top. All this work is got without any additional expenditure of steam, and is thus clear gain.

The amount of the gain, in the case now supposed, may be thus calculated approximately. Find a number of ordinates, as gh was found, at points equally distant from one another, from c to f; from these find a mean pressure or ordinate, and multiply by cf, and the product will be the area of the figure *cdhlf* nearly. The more ordinates are taken, the result will be the nearer the truth. If we take the three ordinates, cd, gh, fl, the mean of which is 43, the result will not be very far from the truth; this gives for the area $43 \times 2\frac{1}{2} = 107{\cdot}5$. If to this is added the area of $abdc = 60 \times 2\frac{1}{2} = 150$, we get the area of the whole figure $abdlf = 257{\cdot}5$; and deducting the area of $akif = 5 \times 15 = 75$, for the resisting pressure above the piston, we have 182·5 as the work done on each square inch of the piston by the expansive stroke. Now, the work of a stroke at full pressure the whole way is 225; but the same quantity of steam that does one stroke at full pressure, will do two strokes expansively, or 365 shewing a gain of 140 units of work to the square inch of the piston, on one cylinderful of steam. The work done by the same quantity of fuel in the two methods is as 225 to 365, or 1 : 1·6.

The figure *kbdli* represents the theoretical work of a stroke; but owing to the causes mentioned before, and to other imperfections, such as leakage, the actual work is more accurately represented by the dotted figure within. By means of an ingenious apparatus called an *Indicator*, the steam in the cylinder is made to record its own state of tension. The piston of a small attached cylinder carries a pencil, and, as it protrudes more or less according to the pressure, traces on a revolving piece of paper a figure like the dotted one in fig. 6.

The higher the pressure of the steam, and the sooner it is cut off, the greater is the saving resulting from the expansive method. The steam is generally cut off much earlier than half-way—at $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c. of the stroke; and the economy is thus much greater than in the case we have supposed. At $\frac{1}{4}$, the economy is stated by writers on the steam-engine to be as much as 1 to 3. The limit to this process lies in the approach of the curve at l to i, when the moving pressure on the piston would be nothing.

The Condensing Engine.—Condensing engines are generally at the same time beam-engines, but not necessarily so. Condensing engines may be worked with steam at the pressure of the atmosphere, or even under; hence they were at one time called *low-pressure* engines, and the non-condensing kind, *high-pressure* engines; but condensing engines are now as often worked with steam at a pressure of several atmospheres, as at low pressure; so that the old designations have ceased to be distinctive.

Fig. 7 is a section of a condensing engine with a

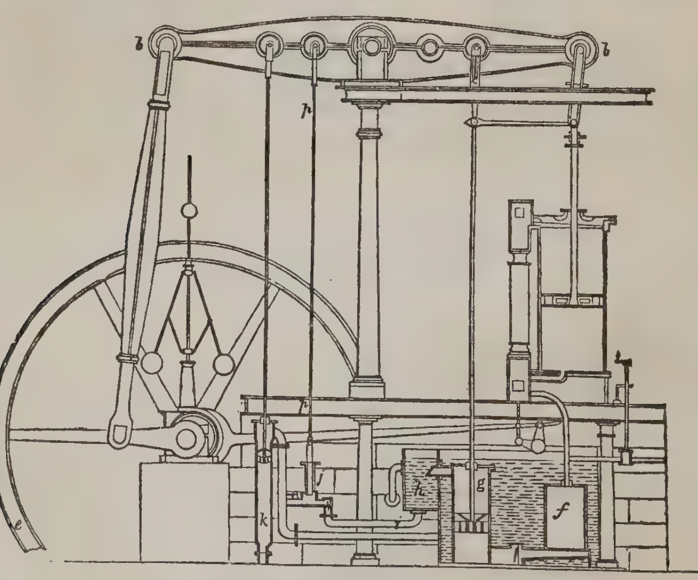

Fig. 7.

beam *ll*, the action of which has been explained above. The fundamental difference between the condensing and non-condensing engine is this: that in the former the steam, instead of escaping into the air, is conducted by the exhaust-pipe into a *condenser*, *f*. This is a vessel exhausted of air, and surrounded by cold water, so that when the steam rushes in, it is deprived of its latent heat, and turned to water. To make the process more rapid, a jet of cold water, which can be regulated by a handle, is injected in a shower through the vessel. This injected water and that of the condensed steam, together with any air that may enter with the water and steam, are pumped out by the air-pump g; the water is delivered, still hot, into the cistern h, from which it is sent to feed the boiler by the hot-water pump *jpp*

k is a cold-water pump for supplying the cistern surrounding the condenser.

The steam enters and leaves the cylinder in much the same way as in the non-condensing engine; but the amount of power developed is calculated somewhat differently. First, let us suppose that steam at the pressure of 1 atmosphere is entering below the piston; then, the upper port being in connection with the condenser, which is theoretically a perfect vacuum, there ought, if the instantaneous escape of the steam were not obstructed by the narrowness of the passage, to be a vacuum above the piston, so that it would move under a pressure of 1 atmosphere, or 15 lbs. to the square inch; but owing to the warmth of the water in the condenser, there must always be a portion of uncondensed vapour in the condenser, having a pressure of several pounds; and from this and other causes, the tension of the steam before the moving piston can seldom be less than 4 or 5 lbs. The real moving-force is thus reduced to perhaps 10 lbs., which, with a piston of 1000 inches in area, and a stroke of 5 feet, gives 50,000 as the work done on the piston in one stroke. Knowing the number of strokes in a minute, the horse-power of the engine may be calculated as before, allowance being made for losses by friction and other causes. In the condensing engine, the air-pump occasions an additional loss of about $\frac{1}{10}$th the total power.

In the beam-engine, the end of the beam to which the piston-rod has to communicate motion necessarily moves in an arc of a circle, while the rod itself must move in a straight line; and the mode of connecting them has always been a difficulty. For this purpose, Watt contrived his *Parallel Motion*, which consists of a system of rods or levers jointed together, so that one point may always move in a straight line.

The action of the *governor*, another of Watt's many inventions, will be understood from fig. 8. An upright spindle has two balls jointed to it, and revolving along with it, the spindle being set in motion by a pulley in connection with some shaft of

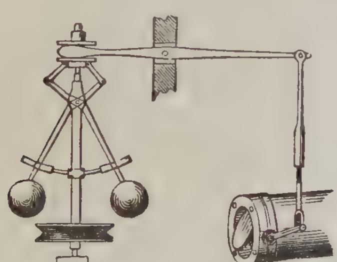

Fig. 8.

the machinery. At the ordinary velocity of the engine, the balls have a certain divergence, but when, as often happens, the resistance to the machinery becomes for a time less, and the speed consequently increases, the balls, having their centrifugal force increased, begin to diverge further. In doing so, the upper ends of the rods by which they hang pull down a boss that slides upon the spindle, and is clasped by the forked end of a lever. This lever is connected with a *throttle-valve*, or circular disc, in the tube that conveys the steam to the cylinder; and the depression of the end of the lever has the effect of closing more or less the passage for the steam, and thus diminishing the driving-force.—For the Boiler and Safety-valve, the reader is referred to these heads.

Engines without beams are called *direct-acting* engines. The piston-rod is made to preserve its parallelism by means of a cross-head *ee* (fig. 2), moving in guides *f*, *f*. A contrivance for rendering the action still more direct, and thus saving room, is

The Oscillating Engine (fig. 9), in which the piston-rod itself is made to turn the crank, and the cylinder is suspended on trunnions, so as to oscillate and accommodate itself to the motion of the crank. This form is chiefly used in marine engines.

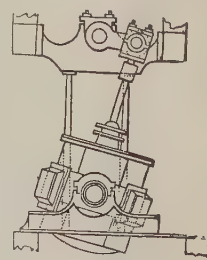

Fig. 9.

Rotary Engines.—As soon as the steam-engine came to be applied to drive machinery by turning a shaft, it was seen how desirable it would be to get rid of the alternating motion of the piston, and make the steam drive the piston round and round, carrying the shaft with it. The saving in expense of construction, in room, and in the loss of power by friction, by thus getting rid of beams and cranks altogether, is so obvious, that innumerable attempts have been made to carry the idea into practice, hitherto, however, with little success. The most promising attempt is the rotary steam-engine invented and patented in 1863 by R. W. Thomson, C.E., F.R.S.E., of Edinburgh. The engraving represents a wooden model made for the

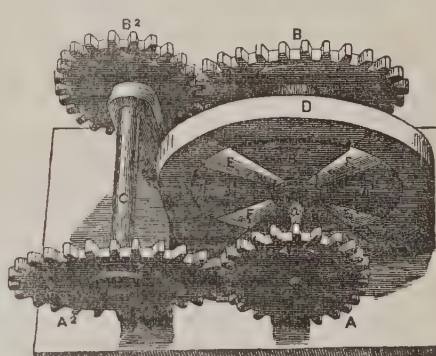

Fig. 10.

purpose of shewing the movements. There is a perplexing simplicity about this machine. It has neither slide-valve, connecting-rod, nor crank. In the cylinder, represented by D, revolve, independently, two steam-tight vanes, one of which, A^1A^1, is keyed on the axis *a*, which passes through one end of the cylinder, and has keyed on its outer end the elliptic teethed wheel A; the other vane B^1B^1 is precisely similar, with its axis passing through the other end of the cylinder, and having keyed on its outer end the elliptic wheel B. On the shaft, C, elliptic wheels A^2 and B^2 are keyed, with their long axes at right angles to each other. The wheels A and A^2 gear into each other, as also B into B^2. Steam is admitted through ports in the sides of the cylinder, at points indicated by the arrows 1 and 3, and escapes, after having done its work, through similar ports at 2 and 4. At first sight, it would seem as if steam acting in the angular spaces, E, E, would force B^1B^1 backwards as much as it forced A^1A^1 forwards. It will be seen that the latter acts on the shaft, C, with a mechanical *advantage*, arising from the short radius of A acting on the

long radius of A^2; while B acts on the same shaft, C, with a mechanical *disadvantage*, arising from its long axis acting through the short axis of B^1. The result of this combination is, that A^1A^1 will move faster and further than B^1B^1; it will overpower B^1B^1, which it will drag after it. The angular distance from 2 to 1 is 45° *less* than that from 1 to 4, and the ellipticity of the wheels is so arranged, that each vane will pass from 2 to 1 in the same time as the other vane passes from 1 to 4 (similar distances being traversed by the other ends of the respective vanes). Steam will continue flowing *into* the angular spaces, E, E, and *out* of the angular spaces, F, F, until the first have become 45° and the last have closed up, which events will coincide with the moment when A^1 has overtaken B^1, and also the whole of the vanes have arrived exactly opposite the ports, 1, 2, 3, and 4. Up to this point, B^1 has been acting as a steam stop or abutment to A^1; but now an interchange of functions takes place, A^1 becomes the slower moving vane and the *point d'appui* to enable B^1 to do its work. At first sight, it looks as if the power required to drag B^1 or A^1, as the case may be, over the spaces 2 to 1 and 4 to 3, were lost; but this is not the case; there is no power whatever lost. The *difference* of travel represents both the available power and the quantity of steam used. In theory, there is neither loss nor gain. In practice, its simplicity, cheapness, and compactness give it great advantages. For screw-propellers, locomotives, and portable engines it is probably destined to find large employment.

The engines used in locomotives are always of the high-pressure or non-condensing kind, and the cylinders of small size; but they do not differ in principle from the non-condensing engines above described. For the peculiarities of the boiler, and the method of causing a powerful draught in the furnace, see BOILER.

Power of the Steam-engine in Relation to Water evaporated and Fuel consumed.—A cubic foot of water, evaporated at ordinary atmospheric pressure, expands to about 1700 cubic feet of steam; and if we suppose it boiled off in a cylinder, *a* (fig. 1), of a foot square in area, it would raise the piston against the pressure of the atmosphere; which would be equal to 2160 lbs., through 1700 feet, or 3,672,000 foot-pounds. In a cylinder with a perfect vacuum above the piston (as in the condensing steam-engine there is an imperfect one), a foot of water evaporated ought thus to give 3,672,000 units of work; or, as a cubic foot of water = 62½ lbs., a pound of water evaporated ought, theoretically, to give 58,752 units of work. Owing to the various imperfections noticed above, average engines do not give more than about 30,000; so that, without expansion, a pound of water evaporated a minute (which is very nearly a cubic foot an hour), may be roundly said to give a horse-power (q. v.), or 33,000 foot-pounds a minute.

The *duty* of an engine is the work done by the consumption of a certain amount of coals, without regard to time. An obstinate adherence to a rule introduced by James Watt for calculating the power of the steam-engines made by him, has led to great confusion in speaking of the working-power of engines. Watt's engines were made to work with a speed of the piston of 200 feet per minute, and were able to lift about 7 lbs. per square inch of piston; and so long as the speed and pressure were according to Watt's practice, his rule was correct enough; but since his time, both speed of piston and pressure on it have vastly increased; and with every increase of speed or of pressure the *real* power has increased in proportion. Watt's rule was: 'The square of the diameter of the piston in inches, multiplied by the cube root of the stroke in feet, and divided by the constant number 47, is the nominal horse power.' See HORSE-POWER. The rule now in use by the Admiralty is: 'The area of the piston in square inches multiplied by 7 lbs. steam-pressure, multiplied by the speed of the piston in feet per minute, and divided by 33,000, will give the nominal horse-power.' This rule is nearly as far off as Watt's from giving the actual power, which is in modern marine engines from three to seven times greater than the nominal power. This excess of the *actual* over the nominal power arises either from an increase in the speed of the piston, or in the pressure of steam acting on it, or from both causes combined; and an increase in either one or both involves a proportionate increase in the quantity of steam used, and therefore of fuel consumed. Extraordinary progress has been made in the last twenty years in reducing the quantity of fuel required to develop a given amount of power. From 7 to 10 lbs. of coal for each horse-power was not considered excessive, but the average consumption is now 3 to 5 lbs. Many steam-vessels are running with a consumption of only 2½ to 3 lbs. of coal per indicated horse-power per hour. Indeed, in several experimental steamers constructed by Mr J. M. Rowan of Glasgow, the consumption of fuel was reduced to 1¼ to 2 lbs. per horse-power per hour; but this economy was obtained by such an exaggeration of several well-known sources of economy, using very high-pressure steam with great expansion, great extent of heating surface in the boiler, &c., that the machinery failed to answer its purpose commercially. The difficulty and expense of keeping steam-boilers and steam-engines in good working order when very high pressures and velocities are used, are so great, that (except in the case of locomotives, where excessive speed of the piston and pressure of steam on it are both essential to develop the requisite power) moderate speeds and pressures are found to be more economical in the end. There is, however, a steady progress in the use of higher pressures and velocities; and as experience and continually improving workmanship advance, doubtless more power will be got out of steam-engines of a given size by driving them faster and with higher pressure of steam. Already the ordinary marine engine gives out four or five times more power than an engine of the same size would have done in Watt's day. Of course the steam-*boilers* must be increased in size and power, in order to supply the greater quantity of steam used by engines which run with high speed and under great pressure.

In connection with his rotary engine, Mr Thomson has invented a form of boiler, which, for generating power in proportion to surface and fuel, is represented as exceeding any hitherto tried. For the smaller class of steam-boilers the vertical form has many recommendations; but in all the vertical boilers hitherto devised there have been drawbacks of a serious kind. Thomson's patent boiler, of which a sectional view is shewn in fig. 11, combines all the good points of the vertical boilers hitherto in use, and has, in addition, its own special merits. The spherical or cylindrical generator, B, receives the full blast of the flames, which actually blow direct on it, impinging on its lower surface with a great force, and then, without losing their velocity, they are deflected against the sides of the furnace. As they rush past the narrow annular space at CC, the flames and heated gases are necessarily brought into actual contact with the sides of the fire-box and with the surface of the spherical generator. The flames and gases are forced to pass in a thin film through this narrow passage, and are thus enabled and compelled to give off to the heating surfaces

nearly all the heat they possess. By the time the hot gases have reached the tube-plate they will have parted with so much heat that they will be no longer hot enough to burn it. In the ordinary vertical boiler the tube-plate is exposed, not only to the

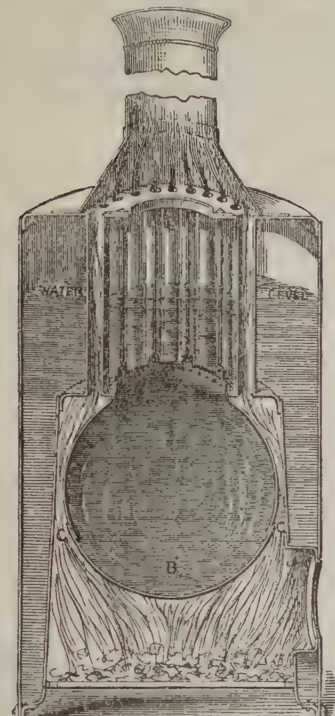

Fig. 11.

direct action of the flames and hot gases, but also to the intense heat *radiating* from the incandescent fuel, and, at the same time, the circulation of the water over the tube-plate is excessively hampered by the tubes standing all over its surface. It soon burns out, as might readily be expected. In the patent boiler the spherical steam generator, B, is interposed between the fire and the tube-plate. Its shape and position are alike perfect for receiving and transmitting to the water within the full effect of the fire without, while, at the same time, it leaves for the tube-plate and tubes only that moderate amount of work which horizontal tube-plates and vertical tubes are capable of doing without being speedily burned out. The rapid circulation of water over the internal, and the quick rush of flame and hot gases over the external surfaces of a steam-boiler, are alike essential and important for the rapid generation of steam. A sluggish and entangled circulation is no doubt the most frequent cause of the poor performances and short lives of very many steam-boilers. The mischievous effect of a coating of soot in a tube is quite well known, and care is taken to remove accumulations of soot and ash from the tubes and flues; but there is no doubt, many steam-boilers are incapable of doing their full work from the constant existence of an internal coating of steam, which in one sense is more injurious than a coating of soot outside.

Externally, neither soot nor ash can settle on any part of the generator B, and the water within whirls around with a velocity that clears the internal surface from steam as quickly as it is generated. The whirling of the water in the steam-generator B, effectually prevents the settlement of mud or any other sediment within it. Every kind of sediment is tossed out of the generator B, and finds a resting-place only in the water-space below the level of the fire-bars, from whence it can be removed from time to time, through hand mud-holes. The difficulty of cleaning out the hard deposits of lime, salt, &c., is a great obstacle to the use of the old kinds of vertical boilers. In Thomson's patent boiler, the facilities offered in this respect leave nothing to be desired. The opening of the man-hole at E, exposes to view the whole interior of the tubes, tube-plates, and central generator. They can all be seen, cleaned and repaired, without any difficulty, and without pulling any part of the boiler to pieces. For working ships, winches, evaporating salt water for the use of the crew and passengers, Thomson's patent boiler possesses extraordinary advantages.

The theory of a perfect thermic engine, which should return in mechanical motion (see FORCE) the greatest possible amount of the heat applied to it, will be considered under THERMODYNAMICS.

STEAM-HAMMER, THE, has doubtlessly contributed more than any other mechanical invention of modern times in developing the wonderful resources of the iron trade, and is still looked upon as a marvel of engineering skill and ability. The first idea of a steam-hammer appears to belong to James Watt, the great father of engineers, and was patented by him in 1784. In 1806, a William Deverell, described as 'an engineer of Surry,' also took out a patent for a steam-hammer; but in neither case does it appear that steam-hammers were actually constructed. From this time till 1837, the idea seems to have been entirely lost sight of, when it was again taken up by Mr James Nasmyth, of the Bridgewater Foundry, Patricroft, near Manchester, as the result of an application made to him by Mr Francis Humphreys, engineer to the Great Western Steam-ship Company, who had been unable to induce any forge-master to undertake the forgings required for the paddle-shafts of the *Great Britain* steam-ship, then in course of construction. Mr Nasmyth sent a sketch of his hammer plan to Mr Humphreys, who, along with Mr Brunel and others, heartily approved of the scheme, but in consequence of an alteration being made in the propelling arrangements of the great ship, the paddle-shaft was not required, and the hammer was not then constructed. The scheme was offered to many of the large forge-masters and engineers; but while all seemed to admire the idea, they failed to appreciate its value and importance, and the hammer remained a mere sketch in Mr Nasmyth's 'scheme-book' till 1842, when, in December of that year, Mr Nasmyth secured a patent for his invention, and the first steam-hammer was made in accordance with his plan at the Bridgewater Foundry early in 1843; but although considered by some as an improvement upon the old 'helves' hitherto used for forging purposes, it was very far from being a perfect or even a marketable tool. See fig. 1. The hammer was worked by means of an ordinary slide-valve and a long lever, requiring great labour and constant attention in order to give the blow required; so that some contrivance was necessary, capable of adjustment, in order to have complete command over the power of the blow, and that, the instant the blow was struck, the block should rise again, so that not only no loss of time should ensue, but that the heat in the mass of iron on the anvil might not be reduced or carried off by the cold face of the block. The peculiar

difficulty of securing a true automatic arrangement will be seen when it is considered that the instant of percussion must vary with almost every blow

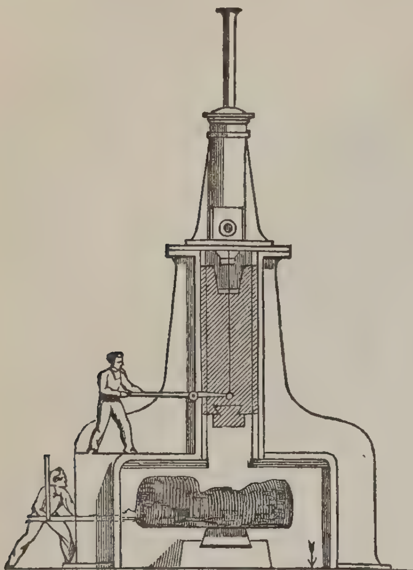

Fig. 1.

that is struck; for the piece on the anvil becomes thinner and thinner by each succeeding blow, and in flat bars, a blow is first given on the flat side, and then on the edge, the difference in the fall of the hammer in the two cases being oftentimes several inches; and further, that the hammer must be under perfect control at all times.

Mr Nasmyth, after many and protracted trials, failed to produce the motion required, and, as a consequence, the whole hammer scheme was on the point of being abandoned. In this dilemma, and during Mr Nasmyth's absence from the works, his partner, Mr Gaskell, applied to their engineering manager, Mr Robert Wilson (at this present time, 1866, managing partner and successor to Mr Nasmyth), to endeavour to solve the problem which had hitherto baffled the skill of Mr Nasmyth. Mr Wilson took the matter in hand, and in little more than a week, a motion was invented and attached to a hammer upon which former experiments had been made, and was at once found to answer most admirably every condition required. Under the influence of this very beautiful mechanical motion every variety of blow could be given, from the gentlest tap to the heaviest blow within the compass of the hammer, and that, too, perfectly self-acting in every respect, the long lever and the hard work before referred to being now entirely banished. By simply altering the position of the tappet lever by means of two screws, a blow of the exact force required could be produced and continued so long as steam was supplied. So completely was the hammer now under control, that it became a favourite amusement to place a wine-glass containing an egg upon the anvil, and let the block descend upon it with its quick motion, and so nice was its adjustment, and so delicate its mechanism, that the great block, weighing perhaps several tons, could be heard playing tap, tap, upon the egg without even cracking the shell, when, at a signal to the man in charge, down would come the great mass, and the egg and glass would be apparently, as Walter Savage Landor has it, 'blasted into space.' On the 18th August 1843, the first hammer was delivered to Messrs Hird, Dawson, and Hardy of the Low Moor Iron-works, near Bradford, Yorkshire, and gave such satisfaction, that orders for this remarkable tool began to flow in from all parts of the country. See fig. 2. The hammer remained in this condition, with the exception of a few minor details, from 1843 to 1853, when Mr Wilson (who in the interim had removed to the Low Moor Iron-works) invented, patented

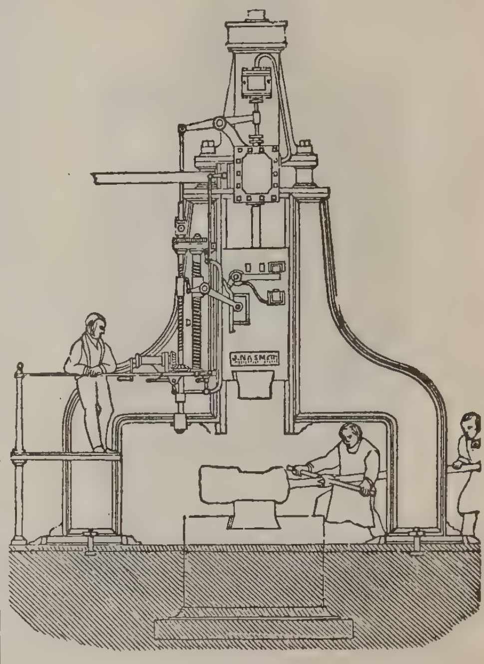

Fig. 2.

and applied to the hammers at Low Moor and elsewhere what is called the 'circular balanced valve.' The *Practical Mechanic's Journal* for 1855, vol. viii., p. 174, in an article on this invention, says: 'The wonders of Mr Nasmyth's invention, the steam-hammer, have just received new lustre at the hands of Mr Wilson, to whom belongs a large portion of the credit attaching to the early practical development of the beautiful automatic action of this invaluable tool. The special feature which Mr Wilson has introduced is his balanced-pressure cylindrical valve, several modifications of which we noticed in our pages of June and July last year. Hammers divested of all self-acting apparatus whatever, and fitted merely with a hand-geared valve of this kind, exhibit an immensely improved action, enabling the workman to obtain the exact kind of blow he wants under all circumstances. This adjustment of the hammering force is attained just as effectually as with the simple hand-hammer of the smith, one stroke giving perhaps a mere touching tap, and the next a blow of the highest intensity.'

In July 1856, Mr Wilson returned to the Bridgewater Foundry as managing partner in the firm of James Nasmyth and Company, and in September following obtained a patent for a *balanced slide-valve*, and at once arranged to apply his invention to all hammers subsequently to be made there, which arrangement continues in operation to the present

time. His balanced slide-valve, by a most ingenious arrangement, allows the valve, as it were, to float in an atmosphere of steam pressing equally upon it on every side, entirely doing away with all superincumbent pressure upon the *valve*, no matter what the pressure in the *boiler* may be. The great advantage of this invention will be apparent when it is stated that hammers are now made of such a size, that, were they worked by an ordinary valve, a power equal to at least 10,000 pounds would be required to work the valve alone, but by means of this invention there is no appreciable pressure whatever, and consequently little or no power required for that purpose.

In June 1861, Mr Wilson patented and introduced another very important improvement, popularly known as the *double-acting hand-gear motion.* By this arrangement, the steam is admitted as before to *raise* the piston, and when it has attained the required elevation, and at the very moment when about to descend, by slightly increasing the travel of the hand-lever (more than when working single-acting), the steam is admitted into the cylinder *above* the piston, which accelerates and increases the intensity of the falling blow and the consequent capacity of the hammer; so much so, that that which had hitherto been described as a 5-*ton* hammer is by this double-action arrangement increased to at least a 12½ or 15 ton one. This great improvement appears to have been produced at precisely the right time, for, in consequence of iron and steel being now so extensively used in the construction of our ships of war, tools and appliances of a heavier and more powerful class than any hitherto in existence are required for manipulating the large plates, shafts, &c., now used in the construction of these floating monsters of the deep.

In 1862, Mr Wilson designed and constructed a small hammer suitable for tilting steel, fitted with the balance-valve, double acting, and with an entirely new self-acting motion (much less complicated than the original one), capable of striking *five hundred* blows per minute.

Hammers, as now constructed, appear as near

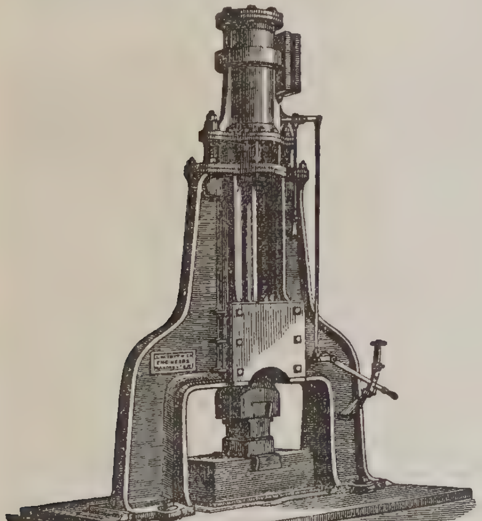

Fig. 3.

perfection as it is possible to conceive them to be, and with blocks of all sizes. from 2 cwt. to 25 tons; notwithstanding, those of the largest and most powerful class are, by means of the improvements above described, worked with as much precision and ease as the merest toy. See fig. 3.

STEAM-NAVIGATION. When once steam was known as a moving power, its application to navigation was obvious enough; it was even to this purpose that the first attempt was made to apply it at all—that of Blasco de Garay—namely, in the harbour of Barcelona in 1543. See STEAM-ENGINE. The only surprising thing is, that thirty years should have elapsed—between 1777, when the steam-engine had become in Watt's hands an efficient power for other purposes, and 1807, the date of Fulton's first voyage—before a really serviceable steam-vessel was produced. The connecting link seems to be the use of revolving-paddles instead of oars. Wheel-boats propelled by oxen, horses, or men were known to the Romans, and were used for ferry-boats in modern times. Some experiments with this mode of propulsion made by Mr Miller of Edinburgh, suggested to his friend Mr Taylor the application of steam as the moving power, and led to the most decided step in the discovery of steam-navigation previous to the final success of Fulton.

As early as 1736, Jonathan Hulls had taken out a patent for a tow-boat to be propelled by a paddle-wheel set in motion by a sort of steam-engine. The project appears never to have been executed. Besides some experiments on the Seine by Comte d'Auxiron in 1774, and Perier in 1775, the Marquis de Jouffroy constructed a steamboat of considerable size in 1782, which navigated the Saone for some time; it was deficient, however, in power. The pioneer in steam-navigation was John Fitch of Philadelphia, who, in 1786, propelled a boat by steam upon the Delaware river, and in 1790, another, as a passenger boat, plied for six months upon the same river, running more than 2000 miles at an average speed of 7½ miles per hour. See *Memoir of John Fitch*, by C. Whittlesey, and *Life*, by Thompson Westcott.

The next important experiment was the one above alluded to, by Messrs Miller and Taylor. It took place on a small lake on Mr Miller's estate of Dalswinton in Dumfriesshire. A small engine having four-inch cylinders of brass was prepared, under the superintendence of Mr Taylor, tutor in Mr Miller's family, and Mr Symington, an ingenious mechanic, and fitted on board a double-boat, with a paddle-wheel in the interspace. The trial took place amid a concourse of hundreds on October 14, 1788, and with perfect success. Next year Mr Miller had larger engines fitted into a vessel, and tried on the Forth and Clyde Canal, when the vessel moved at the rate of seven miles an hour. Partly from caprice, partly from derangement of his affairs, Mr Miller was diverted from pursuing the matter farther. But in 1801, Mr Symington took out a patent for the construction of steamboats, and in 1803 built the *Charlotte Dundas*, to tow vessels on the Forth and Clyde Canal. The success seems to have been complete, excepting in one respect, that the agitation of the water by the paddles was found to wash down the banks in an alarming manner. The use of the vessel was therefore given up, and it lay at *Lock Sixteen* for many years.

In the meantime, attempts had been making at steam-navigation in America by Stevens, Livingston, and others. Robert Fulton, another American, had thought of steam as a motive-power for vessels as early as 1793. Travelling into Scotland he visited the unfortunate *Charlotte Dundas*, and obtained drawings of the machinery. Returning to America with one of Bolton and Watt's engines of 20 horse-power, he, in conjunction with Livingston, built a vessel called the *Clermont*, at New York, and is

1807 made the first really successful voyage by steam from New York to Albany, up the Hudson. The vessel sailed 110 miles in 24 hours, against stream and wind. Fulton has thus indisputably the honour of having first proved the practical utility of steam-navigation. Yet nothing but perseverance seems to have been wanting to crown the experiments of Miller, Taylor, and Symington with equal success. Five years later, 1812, Henry Bell of Glasgow, who had witnessed the experiments on the Canal in 1789, and had accompanied Fulton on his visit to the *Charlotte Dundas*, started a steamboat, the *Comet*, on the Clyde, and was thus the father of steam-navigation in Britain.

In 1815, a steamboat made a passage from Glasgow to London, and in 1818, one plied from New York to New Orleans; it was not till 1820 that steam-packets were established between Holyhead and Dublin. 1838 was a memorable year in the history of steam-navigation. The steamer *Sirius* sailed from Cork on the 4th of April, the *Great Western* from Bristol on the 8th of the same month; both arrived at New York on the 23d, the *Sirius* being only twelve or fifteen hours before the other. The passage is now often made from New York to England in eight or nine days. Steam-vessels are now to be found on all seas and lakes and navigable streams. War-steamers have taken the place of the old ships of the line; and except for the transport of heavy goods to long distances, steam bids fair to supersede the use of sails. The maximum speed yet attained by steam-vessels is 20 miles an hour; the ordinary rate 8—15 miles.

The steam-engine employed to propel a vessel does not differ essentially from any other; but some modifications are necessary, chiefly with a view to secure lightness and economise space. The beam is placed, not above the cylinder, but more on a level, and is often altogether dispensed with, the motion being communicated to the crank by more simple connections, and in the case of the oscillating cylinder, directly by the piston-rod. It is common to have two distinct engines working separate cranks upon the same axle. See STEAM-ENGINE; PADDLE-WHEEL; SCREW-PROPELLER.*

* On the conflicting claims to the merit of this invention, we may here note, in addition to what is said under the head of Screw-propeller, that the application of the screw to the propulsion of vessels is well known to have been tried at least before the middle of the 18th century. In the *Traité de Navire* by Bouguer (Paris, 1746), it is stated that 'revolving arms like the vanes of a windmill were tried for the propulsion of vessels.' In 1751, Daniel Bernouilli, the famous mathematician, in his *Recueil d'Ouvrages Curieux* describes and gives drawings of the screw-propeller. In 1770, James Watt mentions a screw-propeller in a letter to Dr Small, who replies that he had tried it. In 1776, D. Bushnell, an American, in an account of a submarine vessel, describes a screw-propeller for moving it. In 1804, J. Stevens tried at New York a vessel fitted with a screw-propeller driven by a steam-engine made by Boulton and Watt. This appears to be the first attempt at propulsion by the screw with steam as a moving power. Colonel Beaufoy has described a spiral oar or screw-propeller, with two spiral rims fixed on arms, which he had seen used in China about the year 1780. Since the beginning of the present century, several hundred patents have been taken out for screw-propellers, and it would be a hopeless task to try to allot to the different claimants their due shares of merit. Hard and costly experience—mere 'trial and error'—have contributed more to the present perfection of the screw than any recent 'inventions.' The name most widely known in connection with the introduction of the screw-propeller is that of Mr Francis Pettit Smith, a farmer near London, who took out a patent in May 1836 for a screw-propeller. This gentleman, who was by no means the first who tried to get the screw into use, was fortunate enough to obtain the assistance of influential capitalists, and after various trials on a small scale, he fitted up the *Archimedes*, a regular sea-going vessel. The complete success of this the first real trial on a large scale, gave to Mr Smith a position which he had well earned, not by his invention or improvement of the screw-propeller, but by demonstrating to the world on a large scale its capabilities. Other inventors were before him in point of time, but most of them confined their operations to trials of models, or, at most, to small boats fitted with screws which were driven by hand. Mr Robert Wilson was very early in the field. He made and exhibited working models of a vessel propelled by a screw in the years 1821—1825. In 1827, his scheme was brought under the notice of the Admiralty, but rejected. From 1828 till 1832, Mr Wilson brought his schemes before various public bodies in Scotland. Small grants were made by the Highland Society and the Society of Arts for the purpose of testing the efficiency of the screw-propeller, and reports of a favourable tenor were made as to its performance in a boat which was tried at Leith under the directions of a committee of the Society of Arts in 1832. Mr Bennett Woodcroft, Mr Robert Wilson, and many others, have contributed greatly to the introduction of the screw-propeller; but as Mr Smith, aided by his moneyed associates, was the first to put the screw into a big ship, and boldly go to sea in her, the world will continue to give him credit for introducing the screw-propeller into actual use, and sometimes, but with less justice, he will get credit for having invented it

STEA'RIC ACID AND STE'ARIN. The composition of stearic acid is represented by the formula $C_{18}H_{36}O_2$; this acid being one of the solid fatty acids represented by the general formula $C_nH_{2n}O_2$. It exists as a glyceride (stearin) in most fats, and is especially abundant in the more solid kinds, such as mutton-suet. It is readily obtained by saponifying suet, and decomposing the hot solution of the soap by tartaric acid. The oily acids which are thus liberated are compressed between hot plates, by which means most of the Oleic Acid (q. v.) which is present is expelled. The solid residue is then to be repeatedly crystallised from alcohol, and afterwards from ether till the fusing-point becomes constant at 159°. If the final solution is allowed to cool slowly, the acid is deposited in beautiful colourless transparent rhombic plates. After fusion it cools into a wax-like, glistening, crystalline mass, devoid of taste or smell. It is insoluble in water, on which it floats, but dissolves in alcohol and ether, its solution reddening litmus powerfully. When heated above its fusing-point, it becomes decomposed into palmitic acid ($C_{16}H_{32}O_2$), palmitone ($C_{31}H_{62}O$), and an oily hydrocarbon. Stearic acid forms both normal and acid salts. The only normal stearates which are soluble in water are the stearates of the alkalies, whose solutions are frothy and form a lather, but on the addition of an excess of water, separate into an acid salt which is deposited in silky crystalline plates, and the free alkali which remains in solution. The stearates of the alkalies are also soluble in alcohol. Chloride of sodium (common salt) has the property of separating the alkaline stearates from their solution. The stearates of the alkalies are the principal constituents of the different kinds of soap. The other stearates are insoluble. Stearate of lead, which is one of the constituents of lead-plaster, is readily formed by mixing solutions of stearate of soda and acetate of lead, when the stearate of lead falls as a heavy amorphous precipitate, sparingly soluble in alcohol or ether, but dissolving freely in oil of turpentine.

The *Bassic Acid* extracted from the oil of the seeds of *Bassia latifolia*, a tree growing in the Himalaya, and the *Stearophanic Acid* obtained

from the berries of *Monospermum Cocculus*, are identical with stearic acid.

The use of stearic acid in the manufacture of candles is described under the head CANDLE. See also OILS AND FATS.

STEARO'PTEN. See OILS AND FATS.

STE'ATITE, or SOAP-STONE, a mineral principally composed of silica and magnesia, with more or less alumina and water. It is found massive, or sometimes assuming the forms of the crystals of other minerals which it has replaced. It is plentiful in many parts of the world, and is found in various parts of America. It is generally white, reddish white, or yellow. It is soft and greasy to the touch, easily cut, but broken with difficulty. It is used in the manufacture of porcelain. It writes readily on glass, and is used by glaziers for marking plates of glass before they are cut with the diamond. Tailors use it for marking cloth before they cut it. It is also used by shoemakers, to give unctuosity to the heels of stockings, that new boots may more easily be tried on. It is sold for such purposes under the names of Briançon Chalk, French Chalk, and Venice Talc. It readily absorbs oil or grease, and is used in powder for extracting spots of them from silken and woollen stuffs. It is the basis of Rouge (q. v.). It is used for imitating engraved stones, being easily cut, and afterwards hardened by heat; after which, it may be coloured by metallic solutions. The *Agalmatolite* or *Figure-stone* of China is a kind of S., containing a little potash. Exquisite specimens of Chinese workmanship in this material are now familiar to every one. The earth which is eaten by the savages of the banks of the Orinoco is a kind of soft steatite.

STEEL. See IRON.

STEEL, JOHN. See SUPPLEMENT in Vol. X.

STEELBOW, in Scotch Law, means goods, such as corn, cattle, straw, and implements of husbandry, delivered by the landlord to his tenant, by means of which the latter is enabled to stock and labour the farm, and in consideration of which he becomes bound to return articles equal in quantity and quality at the expiration of the lease.

STEELE, SIR RICHARD, was born in Dublin in the year 1671. His father, who held the office of secretary to the Duke of Ormond, was of an English family, but his mother was Irish; and the son appears to have inherited from her the impulsive ardour, tenderness, bright fancy, and reckless profusion immemorially ascribed to the Irish national character. He was educated at the Charter-house School, along with his illustrious friend Addison, and from thence was removed to Merton College, Oxford. Leaving college without taking a degree, he enlisted in the Horse Guards, for which imprudence he was disinherited by a rich relation of his mother, who had named him as heir to an estate in Wexford. In the army, he rose to the rank of captain, but was gay, thoughtless, and dissipated—always sinning and repenting, as he himself confesses. To impose a check on his irregularities, he wrote a religious treatise, *The Christian Hero*, published in 1701, the design of which was to shew that no principles but those of religion are sufficient to make a great man. This public profession of seriousness had little effect on the volatile captain, and he next took to writing comedies. In 1702, he produced *The Funeral, or Grief à la Mode;* in 1703, *The Tender Husband;* and in 1704, *The Lying Lover*—the last a decided failure. About the same time, he obtained some fortune by marrying a West Indian lady, who survived the marriage only a few months; and in 1706, he got the appointment of Gazetteer, with a salary of £300 per annum, and also the post of Gentleman Usher to Prince George, which added another £100 to his income. In the following year (September 9, 1707), he married a Welsh lady, Mary Scurlock, who figures conspicuously in his correspondence as the 'Dearest being on earth,' 'Dear Prue,' and 'Dear wife,' to whom he addressed some 400 letters—admiring, apologetic, and passionate. A course of extravagance—town and country houses, horses and chariots—soon involved the pair in difficulties. Mrs Steele had a fortune of £400 a year, and was thrifty; but the lady's mother had a life-interest in the estate, and was hard and uncongenial. Addison gave a loan of £1000, which was repaid within a twelvemonth; but he made other advances, secured by a bond on house and furniture. He put the bond in execution, sold the house and furniture, and remitted the surplus to his imprudent friend. For this seeming harshness Addison has been blamed; but it rests on good authority that the sufferer himself entertained no such feeling: he regarded the incident as a warning meant to do him service, and he met his friend again with his wonted composure and gaiety. In 1709, S. commenced *The Tatler*, a periodical published thrice a week, containing short essays on life and manners, town gossip or *tattle*, and articles of foreign and domestic news, for which S.'s appointment of Gazetteer furnished him with peculiar facilities. Addison joined cordially in this publication, and still more effectively in its successor, *The Spectator*, a daily literary journal of a higher tone and character, which was continued with unexampled success through 635 numbers. A third miscellany of the same kind, *The Guardian*, was extended to 175 numbers. S. afterwards attempted other periodicals, as *The Lover*, *The Reader*, &c., but these were short-lived. His fame rests on his essays in the *Tatler*, *Spectator*, and *Guardian*, to which he contributed respectively 188, 240, and 82 papers. In the keen political strife of that venal age, S. fought courageously and honestly for the Hanover succession and Whig principles. He lost his office of Gazetteer, and was expelled the House of Commons, for writing a pamphlet called *The Crisis*, in which he warned the nation that the Protestant cause was in danger. But when Queen Anne died, and the Whigs were again triumphant, S. participated in the royal favour. He obtained an appointment in the king's household, was elected M.P. for Boroughbridge, and received the honour of knighthood. In 1717, S. was nominated one of the commissioners for the forfeited estates in Scotland, and he seems to have made four annual visits to Edinburgh on the business of this commission. He was led into a controversy with Addison, a few weeks before the death of the latter, on the once-famous Peerage Bill—a proposal by ministers for restraining the king from any new creation of peers, except upon the extinction of an old family. On this question S. took the side of the crown, and fairly beat his opponent in argument and in temper, besides enjoying the triumph of seeing the bill thrown out. The friends, alas! met no more. The survivor struggled on among controversies, embarrassments, and lawsuits; he was patentee of Drury Lane Theatre; and in 1722, he produced his admirable and successful comedy of *The Conscious Lovers.* His health now rapidly failed. His wife had died in 1718, but he had children to solace his decline. The last three years of his life were spent in retirement in Wales, and there his chequered existence came to a close: he died at Llangunnor, near Carmarthen, on the 21st of September 1729.

The essays of S. have eclipsed his dramas. His Bickerstaff, the Spectator Club, allegories, and short tales have the true, ever-living dramatic spirit. In

taste and delicate humour, he was greatly inferior to Addison; but in invention and insight into human character and motives, he was fully his equal. He knew the world better, and he sympathised with almost every phase of life and character except meanness and cruelty. He seems to have considered it to be his special mission to reform the minor vices and absurdities of English society. If his satire had been more keen and trenchant, or his moral lessons more formal and didactic, he could not have succeeded as he did: his essays were just adapted to the times—they insinuated morality and benevolence, and supplied innocent enjoyment mingled with instruction. The lively, natural writer and companion is never lost in the teacher, nor the gay captain of horse wholly absorbed in the author.

STEEL TOYS. This is a manufacturing term much used in Birmingham, London, and elsewhere. It has a somewhat different meaning from that which would at first sight be given to it. Steel toys are small articles, such as cork-screws, buckles, boot-hooks, and a great variety of similar objects, when made of polished steel. Birmingham and Sheffield are the chief seats of this industry, which employs a large number of operatives and considerable capital.

STEE'LYARD. See BALANCE.

STEEN, JAN, a celebrated Dutch painter, was born in 1626, or according to others in 1636, at Leyden, where his father was a brewer. He shewed an early predilection for art, which led to his being apprenticed to a German painter, Nicholas Knupfer of Utrecht. Subsequently he became a pupil of Van Goyen, whose daughter Margaret he married. Very soon his repute became established. As he worked, however, in a slow and elaborate manner, his gains were insufficient, and he started a brewery at Delft. This enterprise promised fairly; but, according to tradition, he was by no means of steady business habits, and so bemused himself with his own beer that very soon he brewed no more of it. Little that is certain appears to be known regarding the subsequent life of S., but numerous unauthenticated anecdotes are in vogue, which, if it could be shewn that they were true, would prove him to be a wretched drunkard; but a late biographer, Van Westerheene, throws considerable doubt on the accuracy of the popular impression. S. died in 1679 or 1689, leaving his family in very destitute case.

As an artist of the Dutch school he ranks high; and his works are now much valued. In humour and spirit they are scarcely surpassed, and their colouring is clear, fresh, and delicate. At times he attempted historical subjects, but his success in these was not great. It was in homely and domestic scenes that his genius truly exhibited itself; and in this field he has scarcely since been quite equalled.

STEEPLE, the tower and spire, lantern, or other superstructure attached to a church. These are usually of stone, but in some cases are carried up from the floor in massive wooden framing.

STEEPLE-CHASE. This singular term is used to designate a kind of horse-race, run not on a prepared course, but across fields, hedges, ditches, and obstacles of every kind that may happen to be in the way. The name and practice are said to have both originated in a party of unsuccessful fox-hunters, on their return home, agreeing to try a race towards the steeple of a village church, the first who could touch the church with his whip to be the winner. This kind of sport soon became popular; and matches were made and sweepstakes entered into—the requirements of the course being simply two flagstaffs placed about two miles apart, from one of which the competitors started, made their way to the other, and returned to the starting-point. Each rider was allowed to go and come as he chose, but the country was often selected on account of its difficulty; high and strong fences, deep and broad ditches, and sometimes even swollen rivers having to be crossed and recrossed. Then came the more regular steeple-chase of modern times over a course marked out by flags, between which the rider must pass in order to win the race. This improvement was introduced about the end of last century, and no further change took place till 1841, when *handicapping* began. This consists in the weighting of horses according to their supposed merits, without reference to age, size, or sex. The first handicap steeple-chase was run at Newport-Pagnell on April 20, 1841, and the sport has since become more and more popular in England, most of the spring and autumn meetings having their steeple-chases, for valuable stakes. Great crowds of people always attend, the very danger of the sport seeming to increase its attractiveness. Serious accidents are not unfrequent; and great courage, coolness, resolution, and judgment are requisite on the part of the rider in a steeple-chase.

STEE'RAGE, in a vessel, is the lowest class of accommodation for passengers.

STEERING is the act of directing the ship's course by means of the Helm (q. v.). It is bad steering when the ship's head is allowed to oscillate first on one side and then on the other of the course she has to pursue. By such steering the distance to be traversed is increased, and a greater resistance is encountered, the sea being struck more obliquely.

STEIN, HEINRICH FRIEDRICH KARL, BARON VON, one of the greatest statesmen that ever conducted Prussian affairs, belonged to an old Rhenish-Franconian family, and was born at Nassau, October 26, 1757. He studied at Göttingen from 1773 to 1777, entered the service of Prussia in 1778, and in 1784, had risen to be at the head of the department of mines for Westphalia. In 1786, he visited England in company with his friends, the Counts von Redern and Schlahberndorf, and carefully studied the institutions of that country, for which he conceived a high admiration, and sought to introduce them at a later period into Prussia. After several minor preferments, he was appointed, in 1797, president of the Westphalian chambers, where he displayed rare administrative talent. In October 1804, he entered the Prussian ministry as chief of the department of indirect imposts, taxes, manufactures, and commerce. In this capacity he effected important ameliorations, particularly by abolishing various restrictions on the internal trade of the nation; yet to his great grief and vexation he found himself incapable of modifying the policy that resulted in the French invasion and conquest. Of a thoroughly conservative and religious disposition, full of pious reverence for the past, so far as it possessed vital energy, but strongly opposed to bureaucracy and military despotism; recognising in the self-governing powers of communities and provinces the only practical guarantee of national liberty, yet, as a baron of the empire, hostile to the anarchic sovereignty of little states, he occupied a political stand-point which procured for him many adversaries and few friends. In 1807, he was dismissed from office by the king, and withdrew to his estate in Nassau; but the peace of Tilsit opened the eyes of his sovereign to the wisdom of S.'s policy, and in less than seven months he was recalled, with the approbation of Napoleon, who had as yet no idea of the deep and earnest patriotism of the minister. S.'s industry was untiring. Seeing clearly

that, in a military point of view, Prussia was powerless for the moment, he set about developing her internal resources by attempting a series of administrative and political reforms, known as *Stein's System*—the principal of which were the abolition of serfage, with indemnification to the territorial lords; the subjection of the nobles to manorial imposts; equality of orders in the sight of the law; the universal obligation of military service; promotion in the state by merit alone, without distinction of caste; and the establishment of a municipal system analogous to that of England. Some of these reforms were carried out by S., and others by his successor, Hardenberg (q. v.).—Meanwhile, he had become suspected by Napoleon. Among other things, an intercepted letter was brought to the French emperor, in which his policy was sharply criticised. S. was obliged to resign (November 1808), and retired to Austria, where he became the centre of a secret national society—the *Tugendbund*. Napoleon, who bitterly hated patriots that stood in his way, confiscated his property. In 1812, S. was summoned to Russia by the Emperor Alexander, and contributed by his counsels to prepare the coalition against Napoleon. After the march of the allies into Saxony, he was appointed president of the council of all the German States; was a leader in all the military diplomacy of that stirring time up to the Congresses of Vienna and Aix-la-Chapelle, in which, however, he took no part, owing to the intrigues of the Bavarian minister, acting for the lesser states of Germany, who knew well that he did not look with a favourable eye on their anarchic autonomy. The absolutists were also against him. S.'s active political career was now finished; henceforth he enjoyed some honourable functions, but no power, and died at Frücht, July 29, 1831.—See Pertz's *Leben des Freiherrn von Stein* (Berl. 1855; 2d ed. 1856). His correspondence with Humboldt, Gneisenau, Eichhorn, Gagern, Niebuhr, &c., is extremely valuable for the political history of the period.

STEI'NBOK. See BOUQUETIN.

STELLA'RIA. See STITCHWORT.

STE'LLERINE (*Rytina*), a genus of *Cetacea*, of the family *Manatidæ* (q. v.), of which only one species is known (*R. gigas*), about 25 feet in length, a native of Behring's Strait, and never observed since the middle of last century, so that it is supposed to be extinct.

STE'LVIO, PASS OF THE (Ger. *Stilfserjoch*), the highest carriage-road in Europe (9176 feet above the sea-level), leads from Bormio, on the Italian side of the Tyrolese Alps, near the head of the Valteline, to Glurns on the Austrian side. It forms part of the great road between Milan and Innsbruck, and was completed by the Austrian government in 1828, at an expense of 3,000,000 florins. The praise bestowed on it in Murray's *Handbook for Southern Germany* is well deserved: 'Whether we consider the boldness of the design, the difficulties of its execution, from the great height and exposure to storms and avalanches, or the grandeur of the scenery through which it passes, the route of the Stelvio is the most remarkable in Europe.'

STEM, in Botany, that part of the plant which, arising from the surface of the ground, and shooting upwards as the root shoots downwards, bears the leaves and flowers. Stems are either simple or branched. They are herbaceous or woody, solid or hollow, jointed or unjointed. Sometimes they are weak so as to be procumbent, although more generally firm and erect; sometimes weak stems are twining, or they are upheld in various other ways by the climbing habit of the plant. Stems are generally round, but sometimes compressed or angular. The arrangement of the leaves and branches, in reference to the stem, is symmetrical, but plants differ from each other in the nature of this arrangement. In the branching of trees, the symmetrical arrangement is often lost, as to the principal branches, in consequence of the death of some of them. In many plants the stem is obsolete, or so abbreviated as to be inconspicuous, forming a mere neck—the *crown of the root*—where the leaves and flower-stalks spring as at once from the root. Very important differences in the structure of stems distinguish the three great classes of plants—Acrogenous (q. v.), Endogenous (q. v.), and Exogenous (q. v.). Stems sometimes creep along the ground, or even under the ground, when they receive the name *rhizome* or *root-stock*.

STEM, of a ship, is that very powerful piece, or combination, of timber, which, being scarfed to the fore-end of the keel, rises nearly perpendicularly to form the bow and cutwater. To it are rabbeted the fore-ends of the planks. It is backed by an equally powerful timber called the Stemson, bearing the same relation to it as the Keelson (q. v.) does to the keel. See also SHIP-BUILDING.

STE'NCILLING, a method of printing letters or designs. The process consists in cutting out the pattern in a thin plate, usually of metal; this is then laid on the surface intended to receive it, and the colour is rubbed into the cut space with a brush, the plate preventing the contact of the colour, except on the space cut out. It is much used for wall and other surface-decoration, as it is a rapid and cheap process.

STE'NDAL, a town of Prussia, province of Saxony, situated on the river Uchte, 38 miles north-north-east of Magdeburg. Pop. about 10,000. It has a cathedral, founded in 1188, five churches, and a gymnasium, and carries on important manufactures of woollens, cottons, tapestries, tobacco, gloves, &c. S. was the capital of the *Altmark* of Brandenburg.

STENO'GRAPHY. See SHORTHAND.

STEPHEN, ST, THE DEACON, called also the Protomartyr, or earliest of the Christian martyrs, was one of the seven deacons whose appointment is related in the 6th chapter of the Acts of the Apostles. The circumstances of his martyrdom are related in the same chapter. His festival is fixed during the festivals which accompany that of Christmas. It is kept with great solemnity, both in the east and in the west. His relics were believed to have been discovered in the beginning of the 5th c., the 'discovery' being commemorated by a festival held on the 3d of August.—In the calendar of the Roman Catholic Church are several other saints of the same name, of whom perhaps the most remarkable is Stephen, king of Hungary in the early part of the 11th century. He died in 1038. His memory is held in great veneration throughout Southern Germany, and churches are met everywhere, dedicated to his name.

STEPHEN, the name of ten popes of the Roman Catholic Church. It is only necessary to refer in detail to the following. STEPHEN I. was the successor of Lucius III., in 253, and his pontificate (253—257) is memorable as affording a topic for the historians who discuss the question as to the early evidences of a Roman *primacy*. The history of Stephen I. is urged as an argument by each party in support of its own view. The advocates of the primacy infer, from several examples of the deposition of bishops by S. in various places, that a power equivalent to the modern primacy of Rome

was even then acknowledged. The adversaries of the primacy contend that the resistance offered to S. by Cyprian (q. v.), on the rebaptising of heretics, is altogether irreconcilable with the general recognition in the 3d c. of any supremacy on the part of the bishop of Rome.—STEPHEN III. plays a most important part in the history of the temporal sovereignty of the Roman see. He was a native of Rome, and was in possession of the see during the occupation (which practically dates from the year 752) of Ravenna, the Exarchate, and the Pentapolis, by Astolphus, king of the Lombards. That king having invaded Rome, and the Byzantine emperor, Constantine Copronymos, having left unheeded the appeals of S. and the Romans for succour, S. had recourse to Pepin, king of the Franks. The latter in vain sent legates to Astolphus, and the pope returned to France with the legates to solicit in person the aid of the Frank monarch, whom he solemnly crowned. Pepin agreed to compel the Lombards to withdraw from these provinces (which form the portion of the states lately in occupation of the Roman see known as the 'Legations'), and to bestow them on the see of Peter. The Lombard king made a promise to that effect; but on Pepin's withdrawal, again renewed his pretensions, and marched upon Rome. S. therefore again recalled Pepin in a most curious letter written in the name and person of St Peter, an invitation with which Pepin at once complied; and having again forced Astolphus to withdraw, he again (notwithstanding a demand from the Byzantine emperor for their restoration to the empire) reinstated the Roman see in its sovereign rights. S. died in 757.—STEPHEN VII., elected in 896, has supplied to historians much matter of discussion, from his strange proceedings in disinterring the corpse of his penultimate predecessor, Formosus, stripping it of its pontifical garments, and condemning it, after a juridical procedure, to lay burial. The circumstances of this curious conflict are not fully understood.—STEPHEN X. was one of the remarkable series of reforming popes in the 11th c., who are believed to have been elected under the influence of the celebrated Hildebrand, and who, by their energetic rule, prepared the way for that great scheme of ecclesiastical organisation of which the pontificate of that eminent man, under the name of Gregory VII. (q. v.), was the final development. It ought to be observed that, although in the series of the POPES (q. v.) printed in this *Encyclopædia* ten pontiffs named Stephen are recited, other catalogues reckon but nine; the discrepancy arising from the omission by some of Stephen II., who was elected in 753. This pontiff died before consecration, and is therefore by some excluded from the series of popes; but, as his election was complete and canonical, we have included his name in our general catalogue.

STEPHEN, king of England, was the third son of Stephen, Count of Blois, by Adèle, or Alise, daughter of William the Conqueror, and was consequently nephew of Henry I., and cousin of Matilda, daughter of Henry. He was born in 1105, brought over to England at an early age, and became a favourite with his uncle, who bestowed on him large estates, both in that country and in Normandy, and procured for him a marriage with Mahout, or Matilda, daughter of Eustace, third Count of Boulogne, and younger brother of the famous Godfrey of Bouillon. By this marriage S. not only inherited the earldom of Boulogne on the death of his father-in-law (1125), but also became related to the royal family of Scotland, for his wife's mother, Maria, was a daughter of Malcolm Canmore. When his uncle Henry resolved to settle the crown on his daughter Matilda, whose first husband was Henry V., emperor of Germany (whence she is often spoken of as the 'Empress Maud'), he naturally relied on his project receiving the support of his nephew; and at a council held in London, January 1127, S., along with all the other dignitaries of the land, lay and ecclesiastical, took the oath of fealty to Maud. A few months later, the widowed empress married Geoffrey Plantagenet (q. v.). On the death of Henry I. (December 1, 1135), S., knowing well the temper and wish of the English people, hurried over to England from Normandy, where he had been in attendance on his dying uncle, and before the year was out had got himself surrounded by a powerful body of the nobles and clergy and crowned at Westminster. His usurpation of the throne was confirmed by a bull of Pope Innocent. But S. was doomed to find his crown a crown of thorns. Although a gallant, generous, handsome prince, immeasurably superior in personal and royal virtues to Maud (who was suspected of having murdered her first husband, who quarrelled with her second, and was altogether a fiery, insolent, unwise, and exasperating female); yet it must not be forgotten that on S. rests the responsibility of causing a civil war as sanguinary, if not as protracted, as the famous *Wars of the Roses*. Listen to the *Saxon Chronicle:* 'In this king's time, all was dissension and evil and rapine. . . . . Thou mightest go a whole day's journey, and not find a man sitting in a town, nor an acre of land tilled. The poor died of hunger, and those who had been men well-to-do begged for bread. Never was more mischief done by heathen invaders. . . . . To till the ground was to plough the sands of the sea. This lasted the nineteen years that Stephen was king, and it grew continually worse.'

We have not space to narrate in detail the struggle of these nineteen years. It is enough to say, that in February 1141, after five years of the hardest fighting imaginable—against David of Scotland, uncle of Maud, who had taken up arms for his niece (see STANDARD, BATTLE OF THE); against Robert, Earl of Gloucester, natural son of the late king Henry, who had also raised the standard of his half-sister; against individual nobles who simply wished to live in anarchic and barbarous independence; and finally, against the power of the church, which he vainly sought to diminish—he was taken prisoner by the Earl of Gloucester, and placed in chains in the Castle of Bristol. Maud was now elected queen by her own party, but her rapacity and other bad qualities soon made her rule intolerable, and the wife of the imprisoned S. (also called Maud or Matilda) found it possible to continue the war, by the help of the Londoners, who were staunch adherents of her husband. S. obtained his liberty in exchange for the Earl of Gloucester, who had fallen into the hands of S.'s friends at Winchester, and the war was resumed with greater violence than ever. The death of the Earl of Gloucester, in 1146, forced Maud to take refuge in Normandy; but a conspiracy of nobles, headed by Ranulph, Earl of Chester, and another quarrel with the church, kept S.'s hands as full of work as before, and no sooner were these matters settled, than Maud's son, young prince Henry, appeared in England (1153), at the head of an army to support his claim to the throne. Fortunately for the nation, so sadly wasted and desolated, a compromise was effected between the two rivals, which saved the necessity of further bloodshed—S. agreeing to acknowledge Henry as his successor. S. died at Dover the year after (25th October 1154).

STEPHENS (Fr. *Estienne*). The family of the celebrated printers and publishers of this name (descended from a noble Provençal family) is found

settled at Paris towards 1500 in the person of Henry Stephens, supposed to have been born about 1470, and died in 1520. In Paris, Henry carried on the business of printer and bookseller for upwards of twenty years. In 1526, Robert, his second son, born in 1503, is found in possession of the business. Every year of Robert's life is marked by the issue from his printing-press of several volumes, many of them masterpieces of art, and all of them surpassing anything of the kind previously seen in France. He was at once printer, publisher, commentator, and author. Though prosperous, he shewed unmistakably that truth—or that which to him was truth—was of more value in his eyes than worldly gain. Having secretly become a convert to the doctrines of the Reformation, he endeavoured for some time to reconcile his convictions with the outward demeanour required by his position. But the convictions were too strong, or the nature of the man too truth-loving. His Bible of 1545, and his Greek Testament of 1549, each drew down upon him a public prosecution; and though the prosecutions failed legally, they were disastrous to his private fortune. Having first sent his family to Geneva, he followed them there in 1549. Robert, his second son, shortly afterwards returned to Paris, where he resumed his father's business, returning to the Roman Catholic church.

In flying from Paris to Geneva, the S. family found that they had but exchanged Roman Catholic for Protestant persecution.

Henry the second, born at Paris in 1528, and succeeding his father Robert on his death in 1559, was repeatedly called before the council, reprimanded, ordered to print cancels, and excommunicated. Though Henry possessed the same literary industry and ability as his father, he was unfortunately deficient in his father's practical turn of mind. Devoted to his art and to his calling, he seems to have been utterly wanting in worldly prudence. In two years we find that he had revised and published more than 4000 pages of Greek text; while at the same time he was writing his *Apologia pro Herodoto*, a work of formidable length and learning. Rendered nervous and irritable by an overworked brain, and by pecuniary difficulties, which were gathering fast around him, the petty surveillance and censorship of the pious pastors of Geneva became intolerable to him. Travelling, originally undertaken from literary curiosity, grew into a necessity of life. In 1578, he visited Paris, where for several years he became a hanger-on of the court of Henry III., who bestowed upon him a pension, which the state of the royal exchequer rendered merely a nominal one. Quitting Paris, he wandered in poverty over Europe, his own family often ignorant of where he was to be found. He died at Lyon in 1598. Great as a publisher and commentator, Henry S. does not seem to have possessed much power as an original thinker. His mastery of Greek seems to have been almost complete, and as a critic of the French language he is still esteemed in France.—See *Caractères et Portraits Littéraires du Siècle XVI*ᵉ., by M. Leon Feugère (Paris, 1864); also article in *Quarterly Review* (Lond., April 1865); and article 'Estienne,' in the *Nouvelle Biographie Générale*.

STEPHENSON, George, was born on the 9th of June 1781, in circumstances of great poverty, his father having to maintain a family of six children on 12*s*. per week, earned by tending a colliery-engine at Wylam, near Newcastle. George's first employment was herding cows at 2*d*. per day, from which he was promoted to hoeing turnips at 4*d*.; subsequently, he was appointed fireman at Midmill Colliery, and at 15 we find him rejoicing on his salary being raised to 12*s*. a week. As fireman, he applied himself to diligent study of the steam-engine, taking his machine to pieces during his leisure hours, and thus gaining a thorough practical knowledge of it. At Black Callerton Colliery, in 1801, by dint of mending shoes and cleaning watches, in addition to his regular employment, S. contrived to save his first guinea. At 21, he had saved as much as enabled him to furnish a cottage in a humble way, and on 28th November 1802, he was married to a young woman named Fanny Henderson. She died in 1804, while her husband was brakesman at Killingworth Colliery. The early life of S. presents a record, whose interest cannot be surpassed, of a contest between determined purpose, industry, and sagacity on the one hand, against poverty on the other. Slowly, inch by inch, we find the inward forces gaining ground upon the outward. Out of his humble gains he contrived to pay 4*d*. a week for lessons in reading, writing, and arithmetic, which were conned over at night, and mastered by the light of his engine-fire. On one occasion, indeed, so hard had the tide gone against him, that even he had nearly given way to despair. 'I wept bitterly,' he says, in allusion to an intention he had formed of emigrating—'for I knew not where my lot in life might be cast.' In 1815, the invention of a colliery safety-lamp, the 'Geordie,' brought his name before the public. The fact of his invention being almost simultaneous with that of Sir H. Davy, gave rise to a long controversy between their respective friends and supporters. In 1819, S. married his second wife, Elizabeth Hindmarsh, the daughter of a farmer at Black Callerton. It was at Killingworth Colliery that he constructed his first locomotive. At first, it was not very efficient; but, subsequently, the grand improvement of the 'steam-blast' carried his experiment to a triumphant issue. Further improvements followed, and in 1821 S. was appointed engineer for the construction of the Stockton and Darlington Railway; the line, on its completion, being partially worked by means of his great invention. The rapid growth of the trade of South Lancashire, together with the unpopular management of the Bridgewater Canal, gave rise, in 1821, to the project of a railway between Liverpool and Manchester. S. was chosen engineer. That he proposed to work the line with an engine which was to go at the rate of 12 miles an hour, was a fact held up as of itself sufficient to stamp the project as a bubble. 'Twelve miles an hour!' exclaimed the *Quarterly Review*—'as well trust one's self to be fired off on a Congreve rocket.'

When the bill ultimately passed, on 16th March 1826, S. was appointed principal engineer, with a salary of £1000 a year. After inconceivable difficulties, the line was completed in 1829. There then ensued the memorable competition of engines, resulting in the complete triumph of Mr S.'s 'Rocket,' which, to the astonishment of every one except himself, was found capable of travelling at the till then undreamt-of rate of 35 miles an hour. 'Now,' exclaimed one of the directors, 'George Stephenson has at last delivered himself.' While occupied in carrying out the vast system of railway which soon overspread the country, S.'s home was at Alton Grange, near Leicester. He saw but little of it, however, as he was often travelling on business for weeks at a time. During the three years ending 1837, he was principal engineer on the North Midland, York and North Midland, Manchester and Leeds, Birmingham and Derby, and Sheffield and Rotherham Railways. In 1836 alone, 214 miles of railway were put under his direction, involving a capital of five millions. He has been known to dictate reports and letters for twelve continuous

hours. But in the midst of his immense business, his heart remained as youthful as ever. In spring, he would snatch a day for bird-nesting or gardening; in autumn, nutting was still a favourite recreation. We find him even at this time writing a touching account to his son of a pair of robins. Strong as he had shewn himself when the world was all against him, he was not less so in the midst of his success. During the railway mania, his offices in London were crowded every day with men of every rank and condition, eager to strengthen their prospectuses by the weight of his name. Where he disapproved—and at this time he almost always did disapprove—he invariably declined, though by acceding he might have made enormous gain; but to make money without labour or honour had no charm for Stephenson. In the autumn of 1845, he visited Belgium and Spain for professional purposes. On his way home he was seized with pleurisy, from which attack he does not seem ever to have thoroughly recovered. He occupied his declining years with the quiet pursuits of a country gentleman, indulging his love of nature, which, through all his busy life, had never left him. He died at his country-seat of Tapton on 12th August 1848. The leading feature of his mind was honesty of purpose, and determination in carrying it out. 'I have fought for the locomotive single-handed for nearly twenty years,' he says; 'I put up with every rebuff, determined not to be put down.' Towards trickery and affectation he never concealed his contempt, while honest merit never appealed to his liberality in vain.—See *Lives of Engineers*, by Samuel Smiles, vol. iii. (Lond. 1862).

STEPHENSON, Robert, only son of George Stephenson, was born on the 16th October 1803. When a boy, he attended a school in Newcastle. In 1820, his father's improving circumstances enabled him to send Robert to the university of Edinburgh, where he seems to have made excellent use of his time. In 1823, we find him assisting his father in the survey for the Stockton and Darlington Railway. Subsequently, he took an active part in the locomotive engine-works started by his father at Newcastle. In June 1824, he went to Mariquita, in South America, on an engineering appointment; but this not suiting him, at the end of three years he returned home by the United States and Canada. He then assumed the management of the Newcastle business. During the discussion as to the power to be employed on the Liverpool and Manchester line, he was in constant communication with his father, to whom his quick perception and rapid judgment were of great assistance. Shortly after the completion of this line, he was appointed engineer of the Leicester and Swannington Railway. Subsequently, he was appointed joint managing engineer, along with his father, of the London and Birmingham line, the execution of which immense work was ultimately almost wholly intrusted to him. In 1829, he married Frances, daughter of John Sanderson, merchant in London. She died in 1842 without issue; and he did not marry again. The London and Birmingham line was completed in such a manner as to raise S. to the very highest rank in his profession. Business now flowed in upon him. In one parliamentary session we find him engaged in 33 new schemes. Projectors thought themselves fortunate if they could procure his services on any terms. The work which he got through was enormous, and his gains large beyond what had then been known in his profession. The Britannia Tubular Bridge, of which undertaking Robert S. was the master spirit, is one of the most remarkable monuments of the enterprise and engineering skill of the present century. It was completed on 5th March 1850, at a cost of £234,450. S. lived to repeat his splendid achievement in the bridge across the St Lawrence at Montreal, and in the two bridges across the Nile at Damietta. In 1847, he was returned to the House of Commons as member for Whitby. On 15th August 1849, he completed the high-level bridge at Newcastle, and in the following year the great viaduct across the Tweed at Berwick. In 1855, the emperor of the French decorated him with the Legion of Honour. At home, the university of Oxford made him D.C.L. In the same year he was elected President of the Institute of Civil Engineers. The immense amount of work which he went through both at home and abroad proved too much for his constitution, originally delicate; while in Norway, in 1859, he was seized by the illness which soon afterwards ended his illustrious career. He died on 12th October 1859. He was buried in Westminster Abbey. It was as a workman that Robert S. was great, his political views being at times rather narrow. Contrasting him with his great rival Brunel, it has been said that the ambition of the latter was to make a great work, that of the former to make a work which would *pay*. Robert S. inherited the kindly spirit and benevolent disposition of his father. He almost worshipped his father's memory, and was ever ready to attribute to him the chief merit of his own achievements. —See *Lives of the Engineers*, by S. Smiles, vol. iii. (Lond. 1862).

STEPPES, the distinctive name applied to those extensive plains which, with the occasional interpolation of low ranges of hills, stretch from the Dnieper across the south-east of European Russia, round the shores of the Caspian and Aral Seas, between the Altai and Ural chains, and occupy the low lands of Siberia. The word, which is of Russian origin, denotes primarily an uncultivated plain of great extent, and has been applied by geographers to the above-mentioned regions as expressive of their flat, semi-barren, treeless character. In spring and early summer, the steppes are clad with a thin covering of green herbage, become parched and barren under the scorching heat and drought of June, and in winter are hid beneath a thick covering of snow, which, raised in huge white thin clouds, and driven hither and thither by furious storms, brings destruction to every living creature within its sweep. The monotony of the steppe is as fatiguing to the traveller as is that of the sandy, arid desert: for hundreds of leagues his eye is compelled to endure the same unvarying level of scanty herbage, unbroken by tree or bush, and bounded by the utmost limits of the horizon; only in spring, while the vegetation is succulent and fitted for pasture, is the solitude broken here and there by herds of horses and cattle, and their mounted guardians. In autumn, when the tall herbage, withered by the heats of summer, has been rooted up and broken by violent winds, it becomes gathered and rolled together into enormous balls, sometimes of from nine to eleven yards in diameter. Here and there are tracts which offer some inducement to the agriculturist; such are the steppe east of the Dnieper, that between the Don and Volga—of inferior fertility, but rich in coal—and the steppes of South-western Siberia, especially those in the government of Tomsk, all of which have been partially colonised; but a very wide extent is hopelessly barren.

STERCULIA'CEÆ, a natural order of exogenous plants, closely allied to *Malvaceæ* and *Byttneriaceæ*, and consisting of large trees and shrubs, natives of warm climates. About 130

species are known. The flowers of some are irregular; and in some they are hermaphrodite, in others unisexual. Many species, particularly of the suborder *Bombaceæ*, are trees of gigantic size, amongst which is the Baobab or *Adansonia* (q. v.) *digitata.* The bark of some species is very fibrous, so that it is made into ropes and coarse cloth. The light wood of *Ochroma lagopus* is used in the West Indies instead of cork. *Sterculia fœtida*, an Indian tree, with excessively fetid flowers, has pale wood, which is very durable, and susceptible of a high polish. Spars of this wood are called *Poon Spars.* The seeds of some species, as of the Silk-cotton (q. v.) trees, are surrounded with silky hairs. The seeds of all the species are oleaginous; those of some are eatable, as those of the CHICHA (*Sterculia chicha* and *S. lasiantha*) of Brazil, which are about the size of a

Chicha (*Sterculia chicha*):
a branch with leaves and flowers; *b*, parts of fructification; *c*, pistil; *d*, transverse section of ovary.

pigeon's egg, and have a pleasant flavour. They are roasted before being eaten. The Cola (q. v.) Nut of Africa is the seed of a *Sterculia.* The whole order agrees with *Malvaceæ* in possessing mucilaginous and demulcent properties. The Gum Tragacanth (q. v.) of Senegal and Sierra Leone is produced by a *Sterculia.* The Durian (q. v.) is the fruit of a tree of this order.

STERE (Gr. *stereos*, solid), the name given to the unit of cubic measure in the French metrical system. It is a cubic *mètre* (q. v.), and equivalent to 35·3165818168 English cubic feet, or 1·3080215487 English cubic yards. The *decastère* is equal to 10 steres, and the *decistère* to the tenth part of a stere. This measure is much used for wood, especially firewood.

STERELMI'NTHA (Gr. *stereos*, solid, and *helmins*, an intestinal worm), a term suggested by Professor Owen, and generally adopted to signify those intestinal worms which have no true abdominal cavity, and which were called 'parenchymatous' by Cuvier. See CŒLELMINTHA.

STE'REOCHROMY, a new process of wall-painting, invented by Professor J. N. von Fuchs, of Munich, which he professes to be superior to fresco-painting, inasmuch as it will admit of any part of the picture being retouched, as in the case of oil-paintings, and is more durable, being protected by a varnish from the effects of the atmosphere.

STE'REOSCOPE (Gr. *stereos*, solid, and *skopein*, to see), an optical instrument of modern invention, by means of which pictures of objects possessing three dimensions, are seen not as plane representations, but with an appearance of solidity or relief, as in ordinary vision of the objects themselves. The more recondite principles of the stereoscope, which are of high interest and importance in their bearing on the philosophy of perception, will be fully considered under VISION, BINOCULAR. The present article will be limited to an historical sketch of its invention and subsequent developments, coupled with an exposition of the optical and mechanical details of its construction.

The essential principle of the stereoscope, the first conception of which by Professor Wheatstone justly ranks as one of the most brilliant optical discoveries of the age, may be thus explained. It is an obvious fact that the eyes being separated by a certain interval of space, all solid objects so near to the observer as to be seen with a sensible convergence of the optic axes, necessarily form retinal pictures, differing as to their perspective projections for each eye. Singular to say, the true import of this plain fact was wholly unsuspected prior to the investigations of Professor Wheatstone, who, in his first paper on this subject, published in the *Philosophical Transactions* for 1838, clearly established the important conclusion, that this dissimilarity of the retinal images is made to subserve an important end in the use of our visual organs—that it is, in fact, the principal originating cause of our immediate perception of the solidity (or relief) of objects adjacent to the sight. The problem he set himself to investigate was: 'What would be the visual effect of simultaneously presenting to each eye, instead of the object itself, its projection on a plane surface as it appears to that eye?' and in order to bring this question to the test of experiment, he devised an instrument which he named the stereoscope, and which, with certain additions more recently proposed by the same author, is shewn in fig. 1.

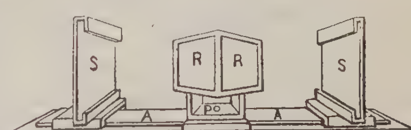

Fig. 1.

RR, two square mirrors about three inches in diameter, fixed vertically with their backs at a right angle with each other; SS, slides for the reception of the pictures, the *left*-hand picture being placed in the *right*-hand slide, and *vice versâ*, on account of the lateral inversion of their reflected images. SS are made to slide along the arms AA, so that their distance from RR may be varied at pleasure. SS also revolve each on a vertical axis, to admit of the variation of their angular position with reference to the arms AA. AA may also be moved in a horizontal plane, on the common pivot P.

The pictures being attached to the slides, the observer places himself with his nose close to, and immediately in front of, the vertical angle made by the reflectors, so that the view by each eye is limited to the rays reflected by its appropriate mirror; the pictures are then seen, as it were, behind the mirrors, and the eyes being made slightly to converge, either by an effort of the will, or by drawing the slides, SS, a little forward, the effect of either of which is to refer the reflected images to the same part of space, the observer sees no longer mere pictorial resemblances, but, to all appearance, the objects themselves, exquisitely modelled, occupying a certain extent of space, and standing forth with a substantiality of aspect truly wonderful. At the outset, the only stereoscopic pictures obtainable were the outlines of geometrical solid figures, which it was possible for a skilful artist to depict

with perspective projections adapted for the right and left eye respectively; and the pictures so prepared excited the greatest interest and admiration. They, moreover, abundantly exemplified the truth and importance of the binocular principle, though the universality of its application to purposes of pictorial illustration only became apparent on the introduction and gradual improvement of the photographic arts. In 1849, Sir David Brewster originated that convenient, portable, and in all respects admirable form of the stereoscope which is now in general use over the whole civilised world. For this—the lenticular stereoscope—the pictures (taken, be it remembered, from two different points of view) are mounted side by side, on a piece of cardboard, and, being placed in the instrument, are viewed through semi-lenses, fixed at the distance apart of the two eyes. To effect the displacement of the pictures, so that they shall be referred to the same part of space, which we have above defined to be an essential condition, Sir David Brewster most ingeniously availed himself of an optical principle, which enabled him at the same time to fulfil several collateral ends of considerable importance. This principle may be described as follows: If an object be viewed through the centre, or, more properly, along the axis, of a convex lens, it will be seen exactly in front of the eye; i. e., in a line with the eye, the centre of the lens, and the actual place of the object. If now the lens be moved slightly to the left, the object will appear to advance towards the right; and, conversely, as the lens is moved towards the right, the object is displaced in the opposite direction. Let the lens be cut in half, transversely, and the two semi-circular pieces reversed as to their former position, i. e., placed side by side, and so that their thin edges shall be adjacent, while the two plane edges, formed by the section of the lens, are kept in mutual parallelism, and have their faces turned outwards, towards the left and right respectively: the right eye will now look through the left half of the lens, and *vice versâ;* and the two pictures, each placed opposite its appropriate eye, and in the principal focus of the eye-piece, will be seen, not in their actual places, but in a position midway between the two. The subsidiary purposes served by this arrangement are, that the pictures are magnified as well as caused to coalesce; and that the equality of the magnifying power of the eye-pieces (a result by no other means certainly attainable) is secured by the fact of their being cut from the same lens, the whole of which is thus advantageously and economically utilised. In too many of the instruments offered for sale, the conditions stated above are very imperfectly fulfilled; the parallelism of the two sectional planes of the semi-lenses, and their rectangularity with two imaginary planes joining their opposite ends respectively, are not maintained, and as a consequence, the coalescence of the pictures is effected, if at all, by a forced and more or less painful displacement of the eye-balls, entirely destructive of all pleasure in the use of the instrument. And it is important to recollect that this parallelism of the sides of the semi-lenses may be either actual or virtual; for to whatever shape they may be cut (and the circular form is the one most often adopted), the foregoing conditions are in no wise altered. The best lenticular form of the instrument with which we are acquainted, is the achromatic stereoscope devised by Messrs Smith, Beck, and Beck, the well-known London opticians, which combines excellencies of a very varied character. Its construction is shewn in fig. 2.

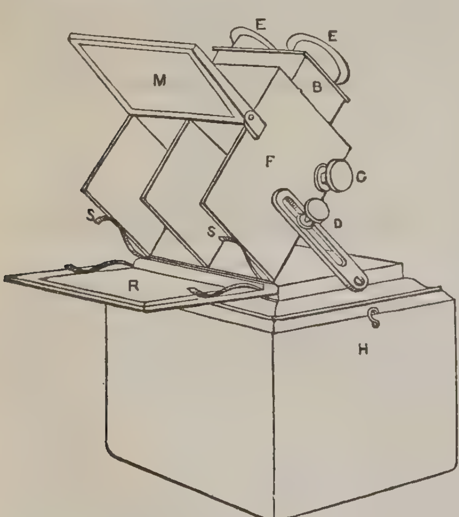

Fig. 2.

EE, the eye-pieces fitted to the sliding-box, B, which, by means of the milled head, C, attached to a rack-and-pinion movement, can be moved out or in for adjusting the focus. D, a slot and screw for fixing the body of the stereoscope, F, at any desired inclination; M, a mirror for reflecting light upon the picture, which is inserted between the springs, SS, and the woodwork of the stereoscope, and is thus firmly held. For viewing transparencies, the flap containing M is closed, and the picture illuminated by light reflected through it by the mirror, R, the inclination of which is adjustable at pleasure; H is a box forming a convenient receptacle for the whole of the instrument.

It remains to speak of the pictures in their relation the one to the other as a stereoscopic pair. Evidently, exactly to reproduce the conditions of normal vision, they should be taken from points of view separated laterally by a space equal to the distance between the eyes, viz., about 2½ inches; and for all objects within narrow limits of distance this rule is observed. But taking a wider range, such as would include, for instance, an extensive architectural pile, photographers usually take their pictures from spots separated by a considerable interval; and the stereoscopic slides thus obtained, when viewed in the stereoscope, exhibit effects of solidity or relief of a very striking character. Inasmuch, however, as these effects are due to a gross exaggeration of the ordinary difference of perspective relatively to the two eyes, they to a like extent misrepresent the actual appearance of the scene; and it were to be wished that for all stereoscopic pairs alike, whether representative of near or of remote objects, photographers would be content to adopt that exact relation of the two retinal pictures which subsists in ordinary binocular vision. As to the mounting of the pictures, it is of course highly important that they be placed exactly in the same line; it has further been pointed out by Mr Claudet that, as the apparent solidity of the objects viewed in the stereoscope conflicts with the evident flatness of the cardboard mount, it is advantageous to adopt the following expedient. The pictures must be of the same size, but instead of having them identically the same as regards the objects represented on each, let the left-hand picture include on its left-hand margin somewhat less than is found on the same margin of the right-hand picture; similarly, let its right-hand margin contain somewhat more than is found on the same margin of the right-hand picture: then will the view appear to extend well out of and beyond the cardboard, which forms, as it were, a framework

around it. A moment's consideration will shew that this ingenious arrangement does but reproduce the conditions which obtain whenever we look out upon a scene through a casement distant from us by a few feet. Availing himself of the libration of the moon, Mr Warren De La Rue has obtained lunar stereoscopic photographs, which exhibit that body with a general appearance of rotundity, while the objects on her surface are seen in conspicuous relief. These effects are, however, evidently due to an exaggeration of the 'binocular parallax;' for by no human eyes, how near soever they might be placed to the lunar surface, could such a view be obtained. It is, as Sir John Herschel has remarked, as though the moon were seen with the eyes of a giant, placed thousands of miles apart.

Among the minor applications of the stereoscope, may be mentioned the STEREOMONOSCOPE and the STEREOTROPE, the former devised by Mr Claudet, the latter by Mr William Thomas Shaw; and severally described by them in the *Proceedings of the Royal Society* of June 1857, April 1858, and January 1861. In the stereomonoscope, the two pictures of a stereoscopic pair are projected, by means of lenses, on to the posterior surface of a piece of ground glass, one upon the other, or so that they occupy the same place; when the observer, looking from the opposite side of the glass, sees them not as a confused mixture of two pictures, but as a single stereoscopic representation, possessing the usual attributes of solidity or relief. The stereotrope consists in an application of the principle of the stereoscope to that class of instruments variously termed thaumatropes, phenakistoscopes, &c., which depend for their results on 'persistence of vision.' In these instruments, as is well known, an object represented on a revolving disc in the successive positions it assumes in performing a given evolution, is seen to execute the movement so delineated; in the stereotrope, the effect of solidity is superadded, so that the object is seen as if in motion, and with an appearance of relief as in nature. A highly ingenious application of the principle of the stereoscope to portraiture has been described by Mr Henry Swann in the *Report of the British Association* for 1863. In this arrangement, the portrait is seen as a solid bust embedded in a cube of crystal. A form of the reflecting stereoscope, in which the planes of reflection are vertical, has been proposed by Mr Walter Hardie.

But by far the most important application of the stereoscopic principle, is its realisation in the binocular microscope of Mr Wenham, the advantages of which over the monocular form of that instrument are increasingly appreciated by microscopists. In this, the right and left eye pictures, respectively, are thus obtained. Immediately behind the object-glass, a small and peculiarly shaped prism is placed in such a position, that it shall receive the whole of the rays coming through the right half of the lens. These rays, after being twice reflected within the body of the prism, finally emerge at such an angle to their original direction, that they cross the undiverted pencil of rays transmitted by the other half of the lens, and are then received into a second tube, which, being inclined to the first or main tube at an appropriate angle, conveys them to the left eye; while the other complement of rays pursues an undeviating course to the right eye. Each of the two tubes is fitted with the usual eye-pieces; and object-glasses of all but the highest powers may be used with pleasure and advantage. For a fuller explanation, see the original paper by Mr Wenham in the *Transactions of the Microscopic Society*, new series, vol. ix., page 15.

STE'REOTYPING (Gr. *stereos*, fixed, solid), the art of fabricating metal plates resembling pages of type, from which impressions may be taken as in ordinary letterpress-printing. The plates, which are composed of type-metal, are about three-sixteenths of an inch thick, perfectly smooth on the back, and having a face exactly resembling a page of movable type. To yield an impression, the plates are fastened by a temporary arrangement to blocks of wood—plate and block together being the height of a type, or one inch. Stereotyping is not employed where only a definite and moderate number of impressions of any work are required. Its chief value consists in its availableness for future impressions contingent on the renewed demand for copies; but it is also of importance in duplicating the means of taking large impressions quickly. Considering the small quantity of metal employed in fabricating a stereotype plate, printers are enabled to secure and store up forms of type, so to speak, at a comparatively small outlay, and have at all times the means ready at hand to produce fresh editions without the trouble or cost of setting a single letter. As in the case of many valuable inventions, there has been not a little discussion as to who was the discoverer of the art of stereotyping. By some it has been ascribed to Van der Mey, a Dutch printer, who early in the 18th c. executed editions of the Bible from forms of fixed type. Van der Mey's process, however, was not stereotyping in the proper sense of the word; for it consisted in nothing more than soldering together all the types in a page in order to fix them permanently. There can be no doubt that the inventor of stereotyping was William Ged, a goldsmith in Edinburgh, who made the discovery about 1725. In 1727, he entered into a contract with a person to prosecute the business of stereotyping; but this person, who had little means, becoming intimidated, the contract was relinquished. In 1729, Ged entered into a partnership for the same object with William Fenner, a London stationer. Afterwards, John James, an architect, Thomas James, a typefounder, and James Ged, son of the inventor, joined the partnership. By this association, certain Bibles and Prayer-books were stereotyped for the university of Cambridge about 1731. Ged's success was so far complete, but his prospects were blighted by ill-treatment from his partners, as well as by the misconduct of the pressmen employed to print from his plates, which they maliciously damaged and rendered imperfect. The university appears to have at length abandoned the use of the plates, which were sent to Caslon's letter-foundry in London to be melted. A few of these plates escaped the crucible, and from two of them, being pages of the Book of Common Prayer, impressions are given in Hansard's *Typographia*, Part II. (1825). Ged's partnership was broken up in 1738, and full of disappointment he returned to Edinburgh. There, he prosecuted his art, and was able to execute several editions of Sallust, of a small size, for the use of schools. Copies of these editions still exist. The earliest which we have seen purports to be printed in 1739, and bears an imprint in Latin which may be translated as follows: 'Not executed by movable types, but by tablets of fused metal.' The printing is as neatly executed as that of any volume at the period. This Sallust of 1739, as we apprehend, was the first book correctly printed from stereotype plates. To add to the cares of William Ged, his son James engaged in the Jacobite insurrection of 1745, and was taken prisoner, and condemned; his life, however, was spared on account of his father's useful invention, and he proceeded to Jamaica, where William, his

brother, was already settled. William Ged, the inventor of stereotyping, died at Edinburgh, October 19, 1749, in very indifferent circumstances.

The art of stereotyping has undergone little change since its discovery by Ged. The process of fabricating plates is very simple. The page of type being set, corrected, cleaned, and fixed in a frame, is laid on a smooth iron table, face upward; a little fine oil is brushed over it, to prevent the liquid stucco from adhering; the stucco to the consistency of cream is now poured over the face of the page, and straightened over it in the process of hardening; when hardened, the cake of stucco is lifted off, and is seen to be a perfect mould of the types. The cake is now baked in an oven and then placed in an iron pan; the pan, which has inlets at the upper side, is plunged into molten metal, which soon runs into the mould; being lifted out and cooled, the pan is opened and found to contain a plate resembling the page of type; the mould is broken and of no further use. When removed from the pan, the plate is rough, and needs to be trimmed for working; for this purpose, it passes through the hands of artisans, who prepare it for the press. Should any particular letter be defective, it is dug out, and a corresponding type inserted; the end of which type is cut off at the back of the plate by a soldering bolt. In preparing plates for press, nothing is more important than giving a high degree of level smoothness to the back, and to effect this certain planing and smoothing operations are adopted. Such is the old and well-known *stucco* process of stereotyping. Latterly, there have been divers improvements as regards the shape of the pans, in order to facilitate the fabrication of several plates at once, but the principle is in all cases the same. After the stereotyping is finished, the types are distributed. In some printing-offices, all work whatsoever is executed from plates, and types are employed only to produce moulds. This however, does not save types from deterioration; in cleaning them with brushes and oiling them for the stucco, their finer parts become in no long time rounded off. As regards impressions from stereotype plates, the work is seldom so sharp and fine as from pages of movable letter; but it answers every required purpose in a large variety of cases. Plates properly manufactured, stored, and mended when necessary, will last for repeated impressions to the extent of hundreds of thousands over a long series of years. The stock of plates in some establishments is accordingly large, and represents a considerable sunk capital. When no longer required, the plates are melted down as material for fresh castings.

The *paper* process of stereotyping was invented some years ago on the continent, but has been since perfected in the *Times* office, where it was adopted for duplicating newspaper forms. See TIMES. A uniform sheet of soft and damp matter is formed by gumming together, first, a sheet of thin yet very tough tissue paper; second, a sheet of loose and bibulous white paper; and third, a sheet of fine-grained and tough brown paper. The smooth and white side of the sheet, still soft and moist, is placed on the types. Both are then put in a press. A roller passes under the form, and presses it up against the paper, so as to receive the impression of the types and convert it into a mould. The dents made by the types rise on the outside of the paper, so that any spot where the paper has not sunk into the spaces between the types is at once detected. Such spots generally occur, and are removed by the paper being driven in between the types by blows of a hard brush. The dents made by the types, we have said, are represented by elevations on the outside of the sheet and the interstices are represented by corresponding hollows. The latter are filled up at this stage by a thin coating of stucco laid on by a brush. The mould is then carefully removed, dried, and placed in a shallow box of metal placed upright. The smooth or stucco side of the mould is pushed against the back of the box. The lid is then closed very tightly, leaving only an opening at the top. Through this opening molten metal is poured, and a plate is thus formed, one side of which, of course, is a cast from the mould. It contains elevations at places where there are wide spaces between the types, and these it is necessary to remove with the chisel. In other respects the plate is an exact copy of the form. The great advantage of this mode of stereotyping is its rapidity. Plates from stucco could scarcely be produced and ready for press in less than six hours; plates from paper can be produced and laid on the machine in less than one hour. Indeed, in the *Times* office, where the process has been carried to great perfection, the plates are now produced in seven minutes. By the paper process, plates are produced every morning for the London newspapers and others of which vast impressions are required. The forms of types themselves are no longer used, a number of plates being produced corresponding to the number of machines employed (see TIMES), and all the copies of the paper are printed from them. A very great saving in the cost of types is thus effected. It was necessary to renew the fount every few months in the *Times* office, when that paper was printed in the usual way. Since the introduction of the new process, however, no new types have been required. They seem as yet not in the least injured, and will certainly last as many years as they did months when printed from. To accommodate printing machines on which the forms need to be fixed in a cylinder, the paper moulds are placed in pans or boxes which are of the required shape. The moulds are then bent with their backs outwards, and the molten metal is poured between the concave mould and convex lid. The plates are generally cast in four segments, which screwed together form a cylinder. They are adjusted to the printing press by a planing machine, which cuts their inner surface to the exact convexity of the cylinder. To this duplication there is of course no limit; sets of plates can be produced to any required number. As copies of old newspapers are not wanted, the plates are melted down as soon as the operations of the day are over. Even when books are printed from movable types, it may serve a good purpose to take paper moulds from them before distribution; for the moulds, on being dried, can be laid aside and be afterwards employed for fabricating plates should a new impression be wanted. The author of a book, for example, could at a most insignificant addition to the expense of typography, possess himself of a set of paper moulds of his work, to be used if necessary at some future period, in order to save the composition for a new edition. W. C.

STE'RLET. See STURGEON.

STE'RLING, an epithet generally applied to the money of the United Kingdom. The original standard of money was weight, and among the Anglo-Saxon and Teutonic nations the basis of weight was in early times supplied by the wheat-corn. Charlemagne superseded the earlier systems by a new coinage, in which a pound of 12 ounces became the money-weight, each pound being divided into 20 solidi, and each solidus into 12 denarii of the weight of 32 wheat-corns. The older *silver* o.

scruple of 24 wheat-corns being superseded by the penny of 32 wheat-corns, the term sterling seems to have been applied to the latter, in consequence of its being in use among the Ripuarian or Austrasian Franks, sometimes called the *Esterlings*, while the old scruple continued to be used by the Northmen. In England, where the change was early introduced, the word sterling came in the course of time to indicate the fineness or standard of the silver; and nearly the same standard, consisting of 11 oz. 2 dwt. of pure silver, and 18 dwt. of alloy to the pound troy, or $\frac{18}{222}$dwt., seems to have subsisted from the 12th c. downwards. The superiority of the English standard silver to all other currency has been generally acknowledged over Europe; and hence the adjective sterling has become a synonym for pure and genuine.

STERNBERG, a town of Austria, in Moravia, 12 miles north-north-east of Olmütz. Pop. 13,500. It is the chief seat of the Moravian cotton manufactures, and has also not unimportant manufactures of linen, hosiery, and liqueurs. The cotton and linen goods made at S., and in the vicinity, are known as *S. wares.*

STERNE, Laurence, though of English descent and parentage, was born at Clonmel, in Ireland, on 24th November 1713. In that country also, in some intermittent way, a good deal of his boyhood was passed, with possibly some effect in developing that oddity and whimsical exuberance long after to find vent in his writings. His father was of a good Yorkshire family, and as lieutenant in a marching regiment led a wandering and unsettled life. When about ten years old, the boy was consigned to the care of his kinsman, Mr Sterne of Elvington, in Yorkshire, by him put to school near Halifax, and thence, on his approving himself a lad of parts, transferred, in 1733, to Jesus College, Cambridge, where, in 1736 and 1740 respectively, he took the degrees of Bachelor and Master of Arts. He was educated for the church, and on his leaving the university, his uncle the Rev. Jaques Sterne, an ecclesiastical dignitary of some magnitude, procured for him the living of Sutton in Yorkshire. With this relative he afterwards quarrelled, but not before another appointment had been secured him as Prebendary of York cathedral. In 1741, he was married to a lady whom he met in York, and soon after, through the influence of a friend of his wife, he was presented to the additional living of Stillington. For nearly 20 years he lived at Sutton unheard of. That his devotion to his clerical duties was great, is more than can be supposed from what we know of his character; and we can readily believe the 'books, painting, fiddling, and shooting,' which he tells us were his choice recreations, formed pretty much the business of his life. Up to the year 1759, in which the first two volumes of his *Tristram Shandy* appeared, he had published only two sermons, which according to his own statement, 'found neither purchasers nor readers.' *Tristram Shandy*, which, though published without his name, was from the first known to be his, had instant and immense success, and S., on going up to London, found himself the literary lion of the day. In 1761, two more volumes of it appeared, followed by vols. 5 and 6 in 1762, vols. 7 and 8 in 1765, and in 1767 by the 9th and last. During this period he also issued 4 vols. of sermons, and the *Sentimental Journey*, published in the beginning of 1768, completes the list of his works. He died on 18th March of that year, his health having been much impaired for some considerable time.

From the time of his becoming famous his parishioners saw of S. but little. He lived mostly either on the continent or in London, where his literary celebrity made him welcome in the best circles. Always an easy, mercurial kind of mortal, he now led a somewhat gay and dissipated life, rather modelled on the Epicurean maxim of enjoying the present hour, than on those more serious precepts he had been wont to enforce from the pulpit. But except that he does not seem to have been excessively devoted to his own wife—she and her daughter being in these pleasant years but little with him—and was a little of a sentimental Lothario in respect of the wives of other people, no very great harm is known of him. He is said, despite of the exquisite sentiment which abounds in his writings, to have been really heartless and unfeeling; and the sneer of Walpole, that he could snivel over a dead ass, to the neglect of his live mother, is familiar to almost every one. It is in fairness, however, to be said that the implied slander rests on no distinct basis of evidence.

Whatever question may be made of the worth of S. as a man, there can be none of his genius as a writer. *Tristram Shandy*, his chief work, must live as long as the language, were it only in virtue of the three characters of Old Shandy, Uncle Toby, and Trim, the most perfect and exquisite, perhaps, in the whole range of British fiction. These are genuine creations, at once fantastic and real, in which the subtlest reconcilement is effected between the sportive exuberance of fancy and the sober outlines of truth. Otherwise there is a good deal in the work which needs excuse; in particular, a most wilful and gratuitous indecency almost without a parallel, and a constant trick of lawless and whimsical digression, to the endless incalculable frivolities of which even the inimitable grace, ease, and tricksy flexibility of the style can with difficulty reconcile the reader. The humour of S. is notwithstanding the most subtle, airy, delicate, and tender to be found in our literature; and in many passages he shews himself master of a pathos equally exquisite and refined. The fullest and, in every way, best account of S. will be found in his Life, in two volumes, by Mr Percy Fitzgerald, published in 1864. Though against the charge of unclerical levity, at once in his writings and his life, it is impossible to defend S., except as the laxer *morale* of his time may afford some slight palliation of it, a candid perusal of this work suggests a considerably more kindly view of his character than that which had previously been current and almost accepted.

STERNHOLD, Thomas, one of the authors of the English version of psalms formerly attached to the Book of Common Prayer, was a native of Hampshire, and born towards the close of the 15th century. He held the office of Groom of the Robes to Henry VIII. and Edward VI., and died in 1549. At the Reformation period, when the practice of singing metrical psalms—first introduced by Clement Marot among the gay courtiers of Francis I.—came to be taken up by the Reformers, S. undertook to render the whole book of Psalms into English verse. He only lived to complete twenty-one psalms; and his version was published after his death under the title of *All such Psalm of David as Thomas Sternhold did in his Lyfe drawe into English metre* (Lond. 1549). S.'s labours were completed by John Hopkins and William Whittinghame, and first annexed to the Book of Common Prayer with the music attached, as *The Whole Booke of Psalmes, collected into English metre by Thomas Sternhold, John Hopkins, and others; compared with the Ebrue, with Notes to sing withal.* S. and Hopkins's psalms are very literal, but somewhat coarse and homely in phraseology. They were used in the church service of England till superseded by the version of Tate and Brady

which appeared in 1698. They were also in use in Scotland down to the middle of the 17th century.

STE'RNIDÆ. See Tern.

STE'RNUTORIES are agents which cause sneezing. The most common are the different kinds of snuffs, but other substances are known which produce a more powerful and prolonged action on the nasal mucous membrane. They have been employed in medicine with various objects; as, for example, to restore suspended respiration in case of fainting, to dislodge foreign bodies from the nasal passages or even the windpipe, to avert or check hysterical attacks, and to terminate prolonged fits of hiccup. They are scarcely ever used at the present day.

STE'THOSCOPE, The (Gr. *stethos*, the chest, and *skopeo*, I look into), is an instrument invented by Laennec for examining the sounds of the chest. Its form will be best understood by the figure, which represents the section reduced to half the natural diameter, or one-eighth of the actual size. The upper part is the chest end, the lower the ear-piece. The most convenient measurements are—length, 7 inches; diameter of the ear-piece, 3 inches; circumference of shaft, 1¼ inch, and diameter of chest end, 1¼ inch. The main object of the stethoscope being to circumscribe and localise the sounds which it transmits, the chest end should be small, in order to determine the exact seat of the greatest intensity of sound. To ascertain this, the instrument should be moved right and left, up and down, till its end is on the exact spot from which the abnormal sound for which we are searching—or, it may be, the absence of sound—proceeds. In the construction of the stethoscope, the following points should be attended to: 1. It should be composed of a material which allows the least amount of sound to be lost, and which least of all modifies or prevents the sound. A porous wood, such as cedar or deal, answers these conditions best, a dense wood, like ebony, having a tendency to modify the sound; 2. It should be of one piece of wood, and not, for example, part ivory and part cedar; 3. The ear-piece should be large and flat to secure perfect apposition and occlusion, and the chest end should be narrow and smoothly rounded over the edge. The various sounds heard through the stethoscope are described in the articles Respiratory Sounds, Pneumonia, &c.

Stethoscope.

STETTI'N, a fortified town of Prussia, capital of the province of Pomerania (*Pommern*), and, after Danzig, the most important sea-port in the kingdom, is situated on the left bank of the Oder, where it flows into the Stettiner-Haff, 83 miles north-east of Berlin, with which it is connected by railway. The entire population of the town in 1880 was 91,745. Across the river, which is here from 12 to 16 feet deep, lies the suburb of Lastadie, connected with S. proper by means of two bridges. Outside the fortifications lie the suburbs of Upper and Lower Wieck and Tornei. The site of the town is hilly, and in consequence the streets are uneven, but the houses are good and the environs very pleasant. The principal buildings are the castle or fortress, the government house, the 'county buildings' with a valuable library, the exchange, and theatre. The chief manufactures are silks, leather, sail cloth, cottons, &c. There is also a large anchor foundry, where all the anchors for Prussian ships are forged. Ship-building and the manufacture of machinery give employment to great numbers; and the commerce of the city is extensive and increasing. S. is the port whence the products of Silesia, both natural and artificial, are mainly shipped to other countries. Corn, wood, and brandy are the principal articles of export. S. owned (1868) 208 vessels, of which 28 were steamers. In 1867, 2214 vessels, of 200,487 lasts (1 last = $1\frac{1}{4}$ tons), arrived at the port of Stettin. The amount of grain exported in 1866 was 805,450 imperial quarters.—*Stettiner-Haff* is formed by an expansion of the River Oder north of the town of S., and is nearly quite shut in from the Baltic by the islands of Usedom and Wollin, having communication with the sea only by three narrow straits, the most important of which is the Swine. See Swinemünde. It has an area of 200 sq. m., and a depth of from 12 to 18 feet.

S., the ancient *Sedinum*, later *Stettinum*, is of Slavic origin, became a flourishing commercial town in the middle ages, joined the Hansa, and was repeatedly the residence of the Dukes of Pomerania.

STEUBEN, Frederic William Augustus, Baron, a general of the American revolutionary army, was born at Magdeburg, Prussia, November 15, 1730; educated at the Jesuits' Colleges of Niesse and Breslau; and at the age of 14 served as a volunteer under his father at the siege of Prague. In 1747 he was appointed cadet of infantry, and in 1758 had risen to the rank of adjutant-general. He was wounded in the battle of Kunersdorf, and in 1761 was conducted as a prisoner of war to St Petersburg, but was shortly after released. The following year he was appointed adjutant-general on the staff of the Prussian king, effected important reforms in the quartermaster's department, and superintended an academy of young officers selected for special military instruction. At the close of the Seven Years' War, he travelled in Europe, and was appointed Grand Marshal and General of the Guard of the Prince of Hohenzollern-Hechingen. Being on a visit to Paris in 1777, where the cause of the American rebellion was favoured by the government, he was invited by Count St Germain to go to America. He arrived at Portsmouth, Virginia, December 1, 1777, and offered his services to General Washington, which were joyfully accepted; and he joined the army, then in the most deplorable condition, at Valley Forge. He was appointed inspector-general, prepared a manual of tactics for the army, remodelled its organisation, and improved its discipline. He was one of the officers who composed the court-martial at the trial of Major André. In the campaign of 1780 he had a command in Virginia, and was on the staff of General Lafayette at the siege of Yorktown. As generous in character as he was capable as an officer, he spent his whole fortune in clothing his men, and gave his last dollar to his soldiers. Congress made tardy reparation, and in 1790 voted him an annuity of 2500 dollars, and a township of land in the state of New York, both of which he divided with his fellow-officers. He died on his estate near Utica, New York, November 28, 1794. See Sparks's *American Biography*, and a Life by Friedrich Kapp (New York, 1860).

STEVENSON, Robert, a Scotch engineer, was born at Glasgow, 8th June 1772. His father, who was a merchant connected with the West India trade, died during his infancy; and his mother having (1786) married Mr Thomas Smith, the first engineer of the Light-house Board, young S. was led to devote himself to the study of engineering,

in which his progress was so rapid that in 1791 he was intrusted by Mr Smith with the erection of a light-house on Little Cumbrae. In 1796, he succeeded his father-in-law as engineer and inspector of light-houses; and during his 47 years' tenure of that office, he planned and constructed no fewer than 23 light-houses round the Scottish coasts; employing the catoptric system of illumination, and his valuable invention of 'intermittent' and 'flashing' lights. The most remarkable of these erections was that on the Bell Rock (q. v.), for which he had been sketching plans for some time, when the wreck of the *York*, a 74-gun ship, on this reef drew general attention to the same subject. The enterprise was quite unprecedented in light-house engineering, for in the only instance at all analogous—the Eddystone Light-house—the rock was barely submerged at flood, while the Bell Rock was never uncovered except at very low ebb tides. In 1814, S. was accompanied in his tour of inspection by Sir Walter Scott, and while the former was projecting another light-house on the Skerryvore (q. v.), near Tiree, the latter was doubtless laying up ample materials for those minute descriptions of the west coast of Scotland and its islands which were afterwards embodied in the *Lord of the Isles*. S. was also in great request as a consulting engineer in the matter of roads, bridges, harbours, canals, and railways, introduced many improvements in their construction, and occasionally co-operated with Rennie, Telford, and others. He died in Edinburgh, July 12, 1850. Like most eminent practical men, S. has left few literary remains; these being merely four volumes of professional printed reports, a large work on the Bell Rock Light-house, some articles in the *Encyclopædia Britannica* and in the *Edinburgh Encyclopædia*, and a series of letters descriptive of the engineering works of the Netherlands in the *Scots Magazine* (1817).

STEVENSTON, a town of Scotland, county of Ayr, is a station on the Ardrossan and Saltcoats branch of the Glasgow and Ayr Railway, and is situated about three miles east of Ardrossan. Pop. 2704. S. consists mainly of one low, straggling, uneven, and narrow street, about half a mile in length; but the parish church is finely placed on a slight eminence, which commands a splendid view of the Arran Hills and the lower scenery of the Firth of Clyde. Cotton-weaving used to be the chief industry of the place, but its prosperity now depends almost exclusively on the collieries and ironworks in its vicinity.

STEWARD OF ENGLAND, LORD HIGH, one of the great officers of state, and anciently the first officer of the crown in England. The dignity was in early times hereditary. From Hugh Grentmesnell, Lord Steward in the time of Henry II., it passed by the marriage of his daughter and co-heir to the family of De Bellomont, Earls of Leicester, and thence also by marriage to the Montforts, Earls of Leicester. On the death and attainder of Simon de Montfort, Earl of Leicester, in 1265, the office, reverting to the crown, was granted with the earldom of Leicester to Edmund, younger son of Henry III., and continued annexed to the earldoms of Lancaster and Leicester, till absorbed into the royal dignity on the accession of Henry IV. Since that time, there has been no permanent Lord Steward, but the office is temporarily revived when occasion requires, a Lord Steward being appointed under the Great Seal *pro hac vice* at a coronation, or the trial of a peer (see PARLIAMENT). When the proceedings are at an end, the Lord Steward terminates his commission by breaking his wand of office.

STEWARD OF THE HOUSEHOLD, LORD, an officer of the royal household in England, of great antiquity, originally designated the Lord Great Master of the Household. He is the head of the ancient court called the *Board of Green Cloth*, and as such has the control of all the officers and servants of the household, except those belonging to the Chapel, the Chamber, and the Stable. The other members of the Board of Green Cloth are the treasurer and the comptroller, over whom, as well as the Master of the Household, the Lord Steward's authority extends. That court had, by 3 Hen. VII. c. 14, and 33 Hen. VIII. c. 12, authority to try and punish all treasons, misprisions, murders, manslaughters, bloodsheds, &c. in the royal palace, and within the verge of the court. But this jurisdiction, which had long fallen into disuse, was in part repealed by 9 Geo. IV. c. 31, and altogether abolished by 12 and 13 Vict. c. 101; and the functions of the Board of Green Cloth are now confined to the supervision of the household expenses and accounts, the purveyance of the provisions and their payment, and the good government of the servants of the household. The Lord Steward selects all the subordinate officers and servants, except those connected with the royal stables; he also appoints the Queen's tradesmen. He is always sworn a member of the Privy Council, and has precedence of all peers of his own degree. He has no formal grant of office, but receives his charge from the sovereign in person, who, delivering to him a white wand as his staff of office, says: '*Seneschal, tenez le bâton de notre maison.*' He holds his appointment during pleasure, and his tenure depends upon the political party to which he belongs. The salary of the office is £2000.

STEWARD or HIGH STEWARD OF SCOTLAND, an office of high dignity and power under the Scottish crown during the 12th, 13th, and 14th centuries (called in Latin *dapifer* or *seneschallus*). The High Steward not only was chief of the household, but collected and managed the crown revenues, and possessed the privilege of holding the first place in the army next to the king in battle. The office was early in the 12th c. conferred by David I. on Walter, second son of Alan, Lord of Oswestry, along with extensive territorial possessions, comprehending among others the barony of Renfrew; and the dignity of steward became hereditary in his family, who in virtue of their office assumed the surname of Stewart. The accession of Robert, the seventh High Steward, to the throne, as Robert II., merged the seneschalship in the crown; but the estates of the stewards afterwards became the appanage of the king's eldest son, and by act of the Scottish Parliament of 1469, the titles of Prince and High Steward of Scotland, Duke of Rothesay, Earl of Carrick, Baron of Renfrew, and Lord of the Isles, were vested in the eldest son and heir-apparent of the crown of Scotland for ever. 'Great Steward of Scotland' has thus become one of the titles of the Prince of Wales. See STEWART, FAMILY OF.

STEWART, THE FAMILY OF. The origin of the Stewarts, long obscured by myth, was rediscovered in the beginning of the present century by the indefatigable antiquary, George Chalmers. Alan, son of Flahald, a Norman, accompanied the Conqueror into England, and obtained by his gift the lands and castle of Oswestry in Shropshire. His eldest son, William, remaining in England, became the ancestor of the Fitzalans, Earls of Arundel, from whom the Duke of Norfolk inherits that earldom through an heiress. The second son, Walter, passing into Scotland in the service of David I.,

had large territorial possessions conferred on him by that monarch, along with the dignity of Steward of Scotland, which became hereditary in his family, and was assumed by his descendants as a surname; some branches of the House, when spelling began to be considered, modifying the orthography to Steuart, or the French form Stuart. The fess chequy adopted as the arms of the family is emblematical of the chequer of the Steward's board. The connection between the Stewarts and Fitzalans was shewn by Mr Chalmers to have been well known and acknowledged as late as 1336, when Richard Fitzalan, Earl of Arundel, sold the Stewardship of Scotland to his sovereign, Edward III., and Edward Baliol, as king of Scotland, ratified the transaction; the sale being a political fiction, founded on a supposed forfeiture of the Scottish branch of the family, by which the hereditary office reverted to the English branch.

The lands conferred on Walter the Steward by David I. included the barony, or what is now the county, of Renfrew, which became the chief patrimony of the family, as well as Innerwick, Hassendean, and other large estates in Teviotdale and Lauderdale. For seven generations the stewardship continued to descend without a break from father to son. Walter, the third, and grandson of the first Steward, held, in addition, the office of Justiciary of Scotland, and was one of the two ambassadors sent to conduct Marie de Couci, second wife of King Alexander II., to her adopted country. His third son, Walter, called Balloch, by his marriage with the younger daughter of Maurice, Earl of Menteith—the lady's elder sister having been banished and her rights forfeited—got the earldom of Menteith, and was ancestor of a line of earls and countesses of Menteith, of whom the Countess Margaret carried the earldom to her husband, Robert, Duke of Albany, son of King Robert II. Alexander, fourth Steward, was regent of Scotland in Alexander III.'s minority; he commanded at the battle of Largs in 1263, when the Scotch army obtained a signal victory over Haco of Norway; and invading the Isle of Man, annexed it to the Scottish crown. From his second son, Sir John Stewart, who married the heiress of Bonkyl, sprung various important branches of the family, including the Stewarts of Darnley, Lennox, and Aubigné. James, the fifth Steward, was one of the six regents of Scotland after the death of Alexander III. Walter, the sixth Steward, occupies a conspicuous place among Bruce's companions-in-arms. When but a youth, he did considerable service as one of the principal leaders at Bannockburn, and, four years later, increased the promise of his fame by his successful defence of Berwick against Edward II. in person. His marriage with Marjory, daughter of Robert Bruce, eventually brought the crown of Scotland to his family. He died at the age of 33, much lamented throughout Scotland. His son by Marjory Bruce, Robert, seventh High Steward, was regent from 1338 to 1341, and afterwards during the captivity of his uncle, David II., from 1346 to 1357; and in the midst of events which threatened a total overthrow to the liberties of Scotland, he exerted himself with zeal and energy in their defence, and was the main instrument in defeating the intrigues of David II. and Edward III. to place an English prince on the throne. On the death of David II. in 1371, he ascended the throne as Robert II., and died in 1390. He was twice married; first to Elizabeth, daughter of Sir William Mure of Rowallan, and afterwards to Euphemia, Countess of Moray, daughter of Hugh, Earl of Ross, and had issue by both unions. In consequence of Elizabeth Mure being related to him within the prohibited degrees, he obtained a dispensation for the marriage from Pope Clement VI. in 1347, in which those children who had already been born, as well as those to be born of that connection, were legitimated; and the succession to the crown was further regulated by parliament. In later times, when the true history of these proceedings was lost or mystified, the descendants of Robert II.'s first marriage came to be branded with the suspicion of illegitimacy, while those of the second marriage were in the habit of boasting of their preferable claim to the throne; and the dispensation setting the question at rest was only discovered in the Vatican in 1789 by Andrew Stuart of Castlemilk. Of the children by the first marriage, the third son, Robert, Duke of Albany, and his issue are separately noticed below. The fourth son, Sir Alexander Stewart, who got the earldom of Buchan on the forfeiture of the Comyns, ruled over the northern part of Scotland with little less than regal authority, and his savage and ferocious character obtained for him the appellation of the 'Wolf of Badenoch.' He had no lawful issue, but several natural sons, one of whom stormed the castle of Kildrummy, the residence of the Countess of Mar, forcibly wedded that lady, and possessed himself of the earldom; and others were progenitors of the branches of the family known as the Athole Stewarts, of whom the principal were the Stewarts of Garth. For the subsequent history of the royal family, see articles ROBERT II. and III.; JAMES I., II., III., IV., V.; MARY, QUEEN OF SCOTS; JAMES I. (of England); CHARLES I. and II.; JAMES II.; WILLIAM AND MARY; and ANNE.

James II. (of England) was twice married, first to Lady Anne Hyde, daughter of Lord Chancellor Hyde; and secondly, to Mary Beatrice, daughter of the Duke of Modena. By the first marriage he had Mary, queen of William III., and Anne, who succeeded to the throne, neither of whom left issue; and by the second, James, Prince of Wales, born in 1688, known as the Chevalier St George, or the elder Pretender. Prince James, who was born but a few months before his father's abdication, was commonly but groundlessly alleged to be a suppositious child, and was involved in his father's exclusion from the crown. In 1715, the party who supported him, known in history as the Jacobites, endeavoured to procure him the throne by force of arms. In Scotland, the Earl of Mar, with about 5000 men, engaged the royal forces under the Duke of Argyll at Sheriffmuir: it was a drawn battle, but the result was a delay as fatal as a defeat. In England, the rising was headed by the Earl of Derwentwater, and ended by the unconditional surrender of the insurgents at Preston, when Lords Derwentwater and Kenmure were beheaded, and other persons of note executed and attainted. James escaped to France; and for the rest of his life resided in obscurity principally at Rome, where he died in 1766. In 1719, he married one of the wealthiest heiresses in Europe, Maria Clementina Sobieski, grand-daughter of John Sobieski, king of Poland, and by her had two sons, Charles Edward Lewis Casimir, born 1720, known as the young Pretender (see STUART, CHARLES EDWARD), and Henry Benedict Maria Clement, Cardinal York, born 1725. Henry Benedict, second son of the Chevalier St George, went to France in 1745 to head an army assembled at Dunkirk for the invasion of England, but the news of the defeat of Culloden put an end to his plan. He then returned to Rome, took orders, and was advanced to the purple by Benedict XIV in 1747. During his brother's life, he was known as Cardinal York; but after his death he assumed

the regal style as Henry IX., king of England. His various bishoprics and rich church livings enabled him for long to live in great splendour; but the expulsion of Pius VI. from Rome, and other events of the Revolution, drove him to Venice, aged and infirm, stripped of his means, and reduced to absolute poverty. His deplorable situation becoming known to the British court, George III. settled on him an annuity of £4000, which the cardinal accepted with gratitude, and enjoyed during the remainder of his life. He died in 1807, at the age of 82, the last surviving descendant of James II.

Next to the exiled Stewarts in representation of the royal house as heir-of-line came the descendants of Henrietta Maria, daughter of Charles I., who was married to Philippe, Duke of Orleans, brother of Louis XIV. of France. This princess had two daughters, of whom the elder, Mary, was queen to Charles II. of Spain, but died childless; the younger, Anna Maria, married Victor-Amadeus, Duke of Savoy and king of Sardinia, and was mother to Charles-Emmanuel III., king of Sardinia, and grandmother to Victor-Amadeus III., king of Sardinia. Victor-Amadeus had three sons who successively occupied the Sardinian throne as Charles-Emmanuel IV., Victor-Emmanuel I., and Charles-Felix, and a daughter who married Charles X. of France, and was mother of Henri, Duc de Bordeaux, present representative of the French Bourbons. Victor-Emmanuel and Charles-Felix left daughters only; and the present senior co-representative as heir-of-line of the House of Stewart, as well as that of Tudor, is Francis V., ex-Duke of Modena, grandson of Victor-Emmanuel IV. by his eldest daughter, Mary Beatrice. Victor-Emmanuel, now king of Italy, comes from the collateral branch of Savoy-Carignan, which does not participate in the Stewart descent.

The branch of the family which the parliamentary settlement called to the throne on the death of Anne were the descendants of the Electress Sophia of Hanover, grand-daughter of James VI. by her mother the Princess Elizabeth Stewart, Electress Palatine and queen of Bohemia. By this destination, not only were the already-mentioned descendants of Charles I.'s daughter, the Duchess of Orleans, excluded, but also the sons of the king of Bohemia and their descendants. The eldest son, Charles Lewis, Duke of Bavaria, is represented through his daughter, the Duchess of Orleans, by the Comte de Paris, grandson of Louis Philippe, late king of the French. Her Majesty Queen Victoria is sixth in descent from and representative of the Electress Sophia, the line of descent being through George I.; George II.; Frederick, Prince of Wales; George III.; and Edward, Duke of Kent.

We have now briefly to notice the most important cadets of the House of Stewart.

Dukes of Albany, Earls of March, Lords of Annandale and Man.—The dukedom of Albany, forfeited on the attainder of Duke Murdoch, nephew of Robert III. (see *infra*), was conferred on Alexander, second son of King James II. of Scotland, who also obtained the earldom of March, and lordship of Annandale and Man. Albany, falling under suspicion of James III., was arrested, and escaping from custody in Edinburgh Castle to France, was attainted. He afterwards took part in a plot with the discontented barons and Edward IV. of England to place himself on the throne, and joining the English army, captured Berwick. After making his peace with James, and being restored to his dukedom, he again rebelled, and invading Scotland with the Earl of Douglas, was routed at Lochmaben, and once more attainted. He was first married to Lady Catherine Sinclair, daughter of the Earl of Orkney and Caithness, from whom he obtained a divorce on the ground of propinquity of blood, by which his son Alexander was bastardised. By his second wife, the daughter of Bertrand, Count de la Tour d'Auvergne, he had a son John, who was restored to the dukedom, assumed the regency of Scotland in James V.'s minority, and was declared heir to the throne. By the settlement of the crown under Robert II., John, Duke of Albany, would, had he survived James V., have had a preferable claim to Mary. After a regency of eight years, during which he gave offence by his hauteur and French predilections, he returned to France, became governor of Bourbonnais, attended Francis I. in his unfortunate expedition into Italy in 1525, and died in 1536. By his wife, Anne de la Tour d'Auvergne, he left no issue.

Dukes of Albany, Earls of Fife and Menteith.—Robert, second surviving son of Robert II. and Elizabeth Mure, obtained the earldom of Menteith by marriage with its heiress, and the earldom of Fife by indenture with his sister-in-law, the countess, and was appointed Great Chamberlain of Scotland in 1383. He practically exercised the regency during his father's declining years, and continued to wield the supreme authority after the succession of his timid and irresolute brother, Robert III., who bestowed on him the title of Duke of Albany—i. e., of all Scotland north of Forth and Clyde. His unscrupulous ambition led him to get rid of his nephew, the Duke of Rothesay, by starving him, in order to pave his way to the throne; and Prince James was sent abroad by his father, lest he should meet a similar fate. On Robert III.'s death, Albany at once became Regent of Scotland, and wielded the chief power of the state during the minority and captivity of James I. By his first marriage to Margaret, Countess of Menteith, he had a son, Murdoch, who, on his father's decease in 1419, succeeded, unchallenged, to the regency. By his second wife, Muriella, daughter of Sir William Keith, the Mariscbal, he had, besides two younger sons of whom there was no succession, a son, John, created Earl of Buchan, on whom Charles VII. bestowed the office of Constable of France after the battle of Baugé, and who fell at Verneuil, leaving only a daughter, who married the second Lord Seton, and is represented by the Earl of Eglinton. Duke Murdoch married the eldest co-heiress of the Earl of Lennox, and had four sons. On James I.'s restoration, his vengeance fell on Duke Murdoch, his sons Walter and Alexander, and his father-in-law, Lennox, who were all put to death, and the dukedom of Albany forfeited to the crown. Murdoch's youngest son, James, generally known as 'James the Gross,' escaped to Ireland, where he had a numerous issue by a lady of the family of the Lords of the Isles, some of whom were brought to Scotland, and raised to high honours by James II., and received letters of legitimation, which in the 15th c. conferred far more nearly than at a later date the full rights of legitimacy. The eldest, who was created Lord Avandale, enjoyed for life the estates of the earldom of Lennox, which had belonged to his grandmother, to the exclusion of the descendants of that lady's sisters; and we afterwards find the Earl of Arran, a descendant of the sixth son of James the Gross, entering a protest in the parliament of 1585 regarding the perfect legitimacy of the house of Ochiltree. From the youngest son, James (not legitimated), sprung the Stuarts of Ardvorlich, Glenbuckie, and others in Balquidder.

Lords Avandale, Ochiltree, and Castlestuart; Earls of Castlestuart.—Andrew Stewart, eldest legitimated son of James the Gross,

and grandson of Murdoch, Duke of Albany, was created Lord Avandale in 1455, and held the office of Chancellor to James III. On his death without issue in 1488, he was succeeded by his nephew, Andrew, eldest son of his also legitimated brother, Andrew, who had three sons. The eldest of these, Andrew, third Lord Avandale, exchanged his title for that of Ochiltree, and was father of Andrew, second Lord Ochiltree, sometimes called the 'Good Lord Ochiltree,' an active promoter of the reformed faith, one of the Lords of the Congregation, an accomplice in the assassination of Riccio. One of his daughters became the second wife of John Knox; and his younger son, James, has an unenviable notoriety in history. He was the unprincipled and arrogant favourite of James VI.'s early years; held along with other offices that of Chancellor of Scotland; was created Earl of Arran on the forfeiture of the Hamilton family; and enriched himself with the spoils of the estates of Angus, Mar, Glammis, and other forfeited lords. But his downfall was as sudden as his elevation. At the Raid of Stirling, in 1585, he was stripped of his honours, offices, and spoils, the earldom of Arran being restored to the Hamiltons; and in 1596, he was assassinated by Sir James Douglas. The second Lord Ochiltree was succeeded by his grandson, Andrew, third Lord Ochiltree, who resigned the lordship of Ochiltree to his cousin, Sir James Stewart of Killeith, son of the Earl of Arran, settled in Ireland, where extensive lands were bestowed on him by James VI., and was in 1619 created Lord Stuart of Castlestuart in the peerage of Ireland. After the death of the fifth Lord Castlestuart in 1684, the title remained dormant till claimed by Andrew, ninth lord, as heir-male of the body of the first lord, which claim was proved to the satisfaction of the Irish House of Lords in 1774. The younger branch of the house, to whom the title of Ochiltree was transferred, had come to an end in 1673, and Lord Castlestuart claimed also the Ochiltree title; but the evidence adduced by him was held insufficient by the British House of Lords. He was, in 1793, created Viscount Castlestuart, and in 1800, Earl of Castlestuart; and the present and fourth earl is his grandson.

LORDS METHVEN.—Henry Stewart, second son of Andrew, second Lord Avandale, became, in 1526, third husband of the Princess Margaret of England, widow of James IV., and divorced wife of Archibald, Earl of Angus. In 1528, he was created Lord Methven. He left no children by the queen-dowager, but by a second marriage had a son, who became second Lord Methven, and in the person of whose son, the third lord, the succession terminated.

LORDS DOUNE, EARLS OF MORAY, LORDS ST COLME.—Sir James Stewart of Beath, third son of Andrew, second Lord Avandale, obtained from James V. the hereditary command of the castle of Doune, with the stewartry of Menteith. He had two sons, from the younger of whom sprang the Stewarts of Burray, in Orkney. The elder son, James, on the dissolution of the monasteries, obtained the lands of St Colme, and was created Lord Doune in 1581. His son, the second Lord Doune, married Elizabeth, the only child of James Stuart, Earl of Moray, Regent of Scotland, natural son of James V. by Margaret, daughter of John, Lord Erskine (see MURRAY, JAMES, EARL OF), and thereupon became Earl of Moray. This nobleman is known in history as the 'Bonny Earl of Moray,' and fell a victim to his hereditary enemy, the Earl of Huntly, in 1592. His son, the third earl, is believed to have got a new investiture to heirs-male, and from him descends the present and twelfth Earl of Moray. The ninth earl became, in 1796, a peer of Great Britain, as Baron Stuart of Castlestuart. Henry Stuart, younger brother of the 'Bonny Earl of Moray,' was made a lord of parliament as Lord St Colme in 1611, a title which, however, became extinct on his son's death without issue, and the estates reverted to the Earl of Moray. The family of Stuart of Dunearn sprang from a younger brother of the fifth earl.

EARLS AND MARQUISES OF BUTE, LORDS WHARNCLIFFE, LORDS STUART DE ROTHESAY.—Sir John Stuart, a natural son of Robert II., was made hereditary sheriff of Bute and Arran; and his descendant and representative, Sir James Stuart, had a baronetcy conferred on him in 1627. Sir James Stuart, grandson of the above Sir James, a privy councillor to Queen Anne, and a strenuous opponent of the Union, was raised to the peerage as Earl of Bute. The fourth earl was advanced to the Marquisate of Bute. The present peer is the third Marquis of Bute. A younger son of the third Earl of Bute was raised to the peerage as Lord Wharncliffe, and a grandson of the same earl as Lord Stuart de Rothesay. The latter title is now extinct.

EARLS OF ANGUS.—Sir John Stewart (commonly called of Bonkyl), brother of James, fifth Steward of Scotland, was progenitor of some of the most considerable branches of the family, and direct ancestor in the male line of James VI. and the Stuart kings who followed him. He married Margaret, daughter and heiress of Sir John Bonkyl of Bonkyl, in virtue of which alliance most of his descendants added the bend or buckle of the Bonkyl coat to the fess of the Stuart escutcheon. The issue of this marriage was five sons—1. Sir Alexander Stewart of Bonkyl; 2. Sir Alan Stewart of Dreghorn; 3. Sir Walter Stewart of Dalswinton; 4. Sir John Stewart of Jedworth; 5. Sir James Stewart of Pierston; and a daughter, Isabel, who married the celebrated Thomas Randolph, Earl of Moray, nephew of Robert Bruce. The eldest son, Sir Alexander, succeeded to Bonkyl on his maternal grandfather's death, and was father of Sir John Stewart, created Earl of Angus in 1329. The third earl, grandson of this Sir John, was the last male descendant of Sir Alexander of Bonkyl; and on his death, the earldom devolved on his aunt, Margaret Stewart, Countess of Angus in her own right. This lady was married to Thomas, Earl of Mar, by whom she had no issue; but she had a natural son, George, by William, first Earl of Douglas (a connection then deemed incestuous, the earl being brother-in-law to her husband), upon whom, on her resignation, the earldom of Angus was conferred by Robert II. in 1389, and who was ancestor of the Douglases, Earls of Angus.

EARLS OF DARNLEY, EARLS AND DUKES OF LENNOX, LORDS OF AUBIGNÉ.—Sir Alan Stewart of Dreghorn, second son of Sir John of Bonkyl, who with his brothers, John and James, fell at Halidon Hill in 1333, was ancestor of this distinguished line. His domains included the extensive lands of Cruickston and Darnley, in Renfrewshire, to which his grandson, Sir Alexander Stewart, added Galston by his marriage with Janeta, daughter and heiress of Sir William Keith of Galston, and widow of Sir David Hamilton of Cadyow. Sir John Stewart of Darnley, eldest son of this marriage, distinguished himself much in the French wars, when succours were sent from Scotland to the aid of the Dauphin, afterwards Charles VII. He was Constable of the Scots army in France, and contributed greatly to the victory of Baugé, in recompense for which the lands and lordship of Aubigné and Concressault, in France,

were conferred on him, as well as the county of Evreux, with permission for himself and his descendants to quarter the royal arms of France. In 1428, he was one of the ambassadors sent by Charles to negotiate a marriage between the Dauphin and the Princess Margaret of Scotland; and in the following year, along with a younger brother, William, fell at the siege of Orleans. His marriage with Elizabeth, one of the daughters and co-heirs of Duncan, Earl of Lennox, afterwards added the Lennox estates to the family possessions. According to arrangements made by permission of the king of France, the lordship of Aubigné was generally enjoyed by a younger member of the family; it went in succession to the third son of Sir John Stuart, and to his son, Bernard Stuart. The latter, alike distinguished for military and statesmanlike qualities, had a share in the victory of Bosworth, and supported by arms Charles VIII.'s claim to the throne of Naples. He held, among other dignities, those of Viceroy of Naples, Constable of Sicily and Jerusalem, and Duke of Terra Nova. His grandson, Sir John Stuart, was advanced to the dignity of a lord of parliament under the title of Lord Darnley; he was also served heir to half the Lennox domains, and claimed the earldom of Lennox. His elder son, Matthew, second earl of Lennox, fell at Flodden; his younger son, Robert, got the lordship of Aubigné in 1508, on the death, without issue, of Bernard Stuart, whose daughter was his first wife. John, the third Earl of Lennox, was son of the second earl by Elizabeth, daughter of James, Lord Hamilton, and niece of James III.; he was one of the lords of the regency in James V.'s minority, and in endeavouring to rescue the youthful king from the thraldom of the Douglases, he was taken prisoner at Linlithgow, and murdered by Sir James Hamilton of Finnart, Arran's natural son. This earl was married to Lady Anne Stewart, daughter of John, Earl of Athole, and had three sons, Matthew—who succeeded him as fourth earl—Robert, and John. The termination of the male line of Robert III. by the death of James V., along with the imperfect legitimacy of the descendants of the house of Albany, placed Matthew, Earl of Lennox, in the position of heir-male of the Stewards of Scotland. He married Lady Margaret Douglas, only child of Archibald, Earl of Angus, by the queen-dowager Margaret, sister of Henry VIII., an alliance which brought his children into the position of being nearest heirs after Mary, Queen of Scots, to the crown of England. The issue were two sons, the elder of them the unhappy husband of the unhappy Queen Mary, and father of James VI. Lennox, after spending his youth in France and in the wars in Italy, returned home in 1543, and took an active part in the negotiations for the proposed marriage of Queen Mary with Edward VI. His subsequent intrigues with England led to his banishment and attainder, but he was recalled and restored to his honours by Mary. After that queen's forced resignation, he was appointed to the regency, and when on his way to hold a parliament at Stirling in 1571, he was attacked by a party of the queen's friends and mortally wounded.

The earldom and estates of Lennox, which, on the death of the fourth earl, had devolved on James VI. by right of blood, were conveyed by him to his uncle, Charles, fifth Earl of Lennox, brother of Lord Darnley. The marriage of this earl in 1574, with a sister of the first Earl of Devonshire, gave great displeasure to Elizabeth, whose own doubtful legitimacy made her very sensitive to possible pretensions to the throne. The sole issue of that union was a daughter, Arabella, and the earldom went in succession to the fifth earl's uncle, Robert, Bishop of Caithness, and his cousin, Esme, son of John Stewart, Lord of Aubigné, youngest son of the third Earl of Lennox, who was created Duke of Lennox. The near relationship to the crown, both of England and Scotland, in which the fifth earl's daughter, the unfortunate Lady Arabella Stewart, stood, made her an object of jealousy equally to James and Elizabeth. Elizabeth first interfered to prevent her contemplated marriage with her cousin, Esme, Duke of Lennox, and afterwards imprisoned her for listening to overtures from a son of the Earl of Northumberland. The result was, that this lady formed an illicit connection with William Seymour, afterwards Marquis of Hertford; on the discovery of which, both were summoned by James before the Privy Council, and severely reprimanded. The consequence was the reverse of what was intended. Lady Arabella privately married Seymour; which becoming known, she and her husband were committed into custody. Both effected their escape: Lady Arabella was overtaken in Calais Roads, and imprisoned in the Tower, where these undeserved oppressions drove her to a condition of lunacy, in which she died, 27th September 1615. Esme, first Duke of Lennox, had two sons, Ludovic and Esme, successively second and third Dukes of Lennox. The former held the offices of Great Chamberlain and High Admiral of Scotland, and was created Earl of Richmond, Earl of Newcastle, and Duke of Richmond in the peerage of England. The latter, who was also Lord of Aubigné, was created Earl of March in England, and was father of James, fourth Duke of Lennox, who fell under the guardianship of James VI. as his nearest heir-male, and had the title of Duke of Richmond, which had expired at his uncle's death, revived in his favour in 1641. On the death of the sixth and last duke without issue in 1672, King Charles II., as nearest heir-male, was served heir to him in special.

Lord Pittenweem.—Alexander Stewart of Galston, younger brother of the first Lord Darnley, got from his brother the lands of Dreghorn and Galston. His great-grandson, Thomas Stewart of Galston, had two sons, Thomas and William. The younger son, William, became commendator of the Priory of Pittenweem, and his son was made a Lord of Parliament as Lord Pittenweem. The line of the elder son, Thomas, failed in 1650 in the person of Ludovic Stuart of Galston.

Stuarts of Castlemilk.—The earliest proved ancestor of this important and well-allied branch of the Stewarts, was Sir William Stewart of Castlemilk, who in 1398 was appointed umpire for the preservation of the Western Marches, probably descended from the Stewarts of Darnley. Archibald Stuart of Castlemilk was created a baronet of Nova Scotia by Charles II. His line failed on the death of Sir John Stuart, fifth baronet, in 1797, when the succession devolved on Andrew Stuart of Torrance and Castlemilk, M.P., the author of *The Genealogical History of the Stewarts*, descended of an uncle of the first baronet, who died without issue.

Steuarts of Allanton, Coltness, &c.—This family, which first came into notice in the 16th c., and includes various men of eminence who would do honour to any line of ancestry, is of unascertained descent, but some traditional accounts make it a branch of Castlemilk. Sir James Steuart of Coltness and Kirkfield, younger brother of Sir Walter of Allanton, and his son, Sir Thomas, were active Covenanters; and the latter, an energetic member of King William's first parliament, and the framer of the Act of 1690 for the regulation of the Church of Scotland, was in 1693 made a baronet. His son, Sir David Steuart of Coltness, accompanied Archibald, Earl of Argyll, in his descent on Scotland, for

which he was sentenced to death, but escaped, and was afterwards pardoned. His brother, Sir Robert Steuart, fourth baronet, was among the more distinguished scientific men of the beginning of the 18th c., and filled the Natural Philosophy chair in the university of Edinburgh, in which he was succeeded by his son. Sir James Steuart of Goodtrees, Lord Advocate under King William and Queen Anne, author of the Answers to *Dirleton's Doubts*, and one of the most eminent jurists of his time, was younger brother to the first baronet of Coltness. His son, Sir James Steuart of Goodtrees and Coltness, also a distinguished lawyer, and created a baronet in 1705, was father of another Sir James, who was Prince Charles's confidential agent at the court of France, and at the same time the author of various works of merit on political economy and kindred subjects.

EARLS OF GALLOWAY.—Sir Walter Stewart of Dalswinton, third son of Sir John of Bonkyl, obtained the lands of Dalswinton from King Robert Bruce, and Garlies from his nephew, John Randolph, Earl of Moray. His grandson, Sir Walter of Dalswinton, left an only daughter, Marion, who married Sir John Stewart, son of Sir William Stewart of Jedworth, and probably a descendant of John, fourth son of Sir John of Bonkyl. Sir Alexander Stewart of Garlies, eighth in descent from Sir John and Marion Stewart, was created Lord Garlies in 1607, and Earl of Galloway in 1623. In 1796, John, seventh Earl of Galloway, was created a British peer as Baron Stewart of Garlies. Randolph Stewart, ninth Earl of Galloway, is present representative.

LORD BLANTYRE.—This branch of the House of S. is descended from Sir Thomas Stewart of Minto, third son of Sir William of Dalswinton and Garlies, the eldest son of the heiress, Marion Stewart. Sir John Stewart of Minto, great-grandson of that Sir Thomas, had two sons. The line of the elder, Sir Matthew, became extinct in the person of Sir John Stuart, who died in the Darien expedition of 1697. The second son, Walter, was educated along with James VI. under George Buchanan, and had the priory of Blantyre bestowed on him by that monarch: he was Privy Councillor, Keeper of the Privy Seal, one of the four Commissioners of the Treasury and Exchequer, called Octavians, and afterwards High Treasurer. In 1606 he was raised to the peerage as Lord Blantyre. The present representative of this branch is Charles Stuart, twelfth Lord Blantyre.

VISCOUNTS MOUNTJOY, EARL OF BLESSINGTON.—Sir William Stewart, descended from Walter Stewart of Tonderghie, fourth son of Sir William of Dalswinton and Garlies, who was in great favour with James VI., and undertaker for the plantation of escheated lands in Ulster, was made a baronet of Ireland in 1623. His grandson, Sir William Stewart, second baronet, was in 1682 created Baron Stewart of Ramalton, and Viscount Mountjoy in the peerage of Ireland. He served in Hungary at the siege of Buda, and in 1688 undertook a mission from Lord-deputy Tyrconnel to James II., then at Paris, when he was thrown into the Bastille, and was a prisoner there for four years. He afterwards joined King William at Flanders, and was killed at the battle of Steinkirk. The second viscount, his son, married the daughter and eventually heiress of Viscount Blessington. Their son, the third Viscount Mountjoy, was advanced to the Earldom of Blessington, which title, as well as that of Mountjoy, became extinct on his decease in 1769, though the baronetcy exists.

EARLS OF ATHOLE, LORDS OF LORN AND INNERMEATH.—Sir James Stewart, fifth son of Sir John of Bonkyl, killed with his brothers Alexander and John at Halidon Hill, had a grant from Robert Bruce of the lands of Pierston and others in Ayrshire, and was father of Sir Robert Stewart of Shanbothy and Innermeath. This Sir Robert had two sons, John and Robert, who married the two co-heiresses of the princely house of De Ergadia, Lord of Lorn, who were also co-heirs of the line of Robert Bruce. The younger son, Robert of Durrisdeer, was ancestor of a line of Stewarts of Rossyth and Craigiehall, to whom Oliver Cromwell's mother is said, on no very certain grounds, to have belonged, and which probably came to an end about 1830. The elder son, Sir John, whose wife was the elder and principal co-heiress, had five sons. The eldest, Robert, became Lord of Lorn; the third, Sir James, known as the Black Knight of Lorn, was husband of James I.'s widow; and his eldest son, brother uterine of James II., was created Earl of Athole, with remainder to the heirs-male of his body. His great-grandson, John Stewart, fourth Earl of Athole, was much involved in the political events of Mary's and James VI.'s time. An adherent of the old faith, and at first a staunch supporter of the queen, he nevertheless assisted in her seizure, and took a lead in the association formed in 1567 for the defence of James VI. He headed the confederacy which took up arms against the Regent Morton, and induced James to call a parliament. In 1577, he became Chancellor of Scotland, and died suddenly under suspicion of poison from Morton. His son, the fifth Earl of Athole, had no male issue, but daughters, of whom the eldest was married to the Earl of Tullibardine; and at his death, the earldom fell to the crown, and was conferred on the elder branch of the House of Innermeath, to which we now revert.

Robert, Lord of Lorn, eldest brother of the Black Knight, had two sons. The elder of these, John, second Lord of Lorn, had three daughters, co-heiresses, who respectively married the Earl of Argyll, Campbell of Glenorchy, and Campbell of Ottar, the lordship of Lorn passing to the Argyll family; he had also a natural son, ancestor of the Stewarts of Appin. The second son of Robert, Lord of Lorn, was Walter, Lord Innermeath, whose descendant and representative, John, sixth Lord Innermeath, obtained the earldom of Athole on the death of the above-mentioned fifth earl; with a remainder to the heirs-male of his body, which came to an end on the death, in 1625, of his only son, who had succeeded him in the earldom. The earldom of Athole was then conferred by Charles I. on the Earl of Tullibardine, grandson through his mother of the fifth Earl of Athole, from whom the existing ducal House of Athole is descended. From Alexander, fourth son of Sir John Stuart of Innermeath, descend the family of Stewart of Grandtully, on whom a baronetcy was conferred in 1683.

EARLS OF BUCHAN.—The earldom of Buchan was, in 1469, bestowed on James Stewart, second son of the Black Knight of Lorn, and brother uterine of James II. By his marriage with the heiress of Auchterhouse, his family became heritable sheriffs of the county of Forfar. His legitimate line ended in the fourth generation in an heiress, Christian, Countess of Buchan, who, marrying a son of Sir Robert Douglas of Lochleven, carried the earldom of Buchan into his family.

EARLS OF TRAQUAIR.—This James Stewart, first Earl of Buchan, had, besides his lawful issue, a natural son, James, legitimated in 1489, on whom his father conferred the lands of Traquair. His descendant, Sir John Stuart, was created by Charles I. Lord Stuart of Traquair in 1628, and in 1633, Earl of Traquair. The title became extinct or dormant on the death of the eighth earl in 1861.

Various works have been written to elucidate the

history of the S. family, or particular branches of it, including Symson's *General and Historical Account of the Stewarts* (Edin. 1712); Hay of Drumboote's *Essay on the Origin of the Royal Family of the Stewarts* (1722); Duncan Stewart's *Historical and Genealogical Account of the Royal Family of Scotland, and of the Surname of Stewart* (Edin. 1739); Noble's *Historical Genealogy of the Royal House of Stewart* (Lond. 1795); and Andrew Stuart of Castlemilk's *Genealogical History of the Stewarts* (Lond. 1798), a work full of laborious research, but nearly confined to the Houses of Darnley, Lennox, and Castlemilk. See also *The Genealogy of the Stewarts refuted* (Edin. 1799), and the rejoinder to it in Andrew Stuart's *Supplement to the Genealogical History of the Stewarts* (1799); Chalmers's *Caledonia* (1807—1824); Crawfurd's *Description of the Shire of Renfrew, with Supplement* by George Robertson (Paisley, 1818); Riddell's *Saltfoot Controversy*, privately printed at Edinburgh, 1819.

STEWART, Dugald. This philosopher was born in Edinburgh, on the 22d November 1753. His father was Matthew Stewart, Professor of Mathematics in the university of Edinburgh. He entered the High School in his eighth year, and remained till his thirteenth. During the last two years of his attendance, when in the rector's classes, he was principally under Alexander Adam, afterwards well known for his classical scholarship, who then began to teach as the rector's substitute. His subsequent course at the university extended from 1765 to 1769. In the departments of study where his own career afterwards lay, he was fortunate to find professors of ability and distinction; the Logic chair was filled by John Stevenson, who lectured on logic, metaphysics, rhetoric, and the history of philosophy; the Moral Philosophy chair was occupied by Adam Ferguson. While S. gave his highest promise in these subjects, he also made great attainments in mathematics and natural philosophy, and likewise in classics. In 1771, he went to study at Glasgow, partly with a view to one of the Snell scholarships at Baliol College, Oxford, and partly to attend the lectures of Dr Reid. It was while there that he wrote an essay on Dreaming, which was his first effort in mental philosophy, and contained the germs of many of his subsequent speculations. He lived in the same house with Archibald Alison, the author of the *Essay on Taste*, and the two became intimate friends through life. He was at Glasgow only one session. In 1772, in his 19th year, he was called upon by his father, whose health was failing, to teach the mathematical classes in the university of Edinburgh; in 1775, he was elected joint professor, and acted in that capacity till 1785. In 1778, Adam Ferguson was absent from his post on a political mission to America, and S. taught the moral philosophy class in addition to his mathematical classes. The lectures that he gave on this occasion were wholly his own, and were delivered from notes, as was his practice in after years. On the resignation of Ferguson in 1785, he was appointed Professor of Moral Philosophy, and continued in the active duties of the class for 25 years. His lectures were greatly admired and numerously attended. He went over a wide compass of subjects: Psychology, or the Science of Mind proper, Metaphysics, Logic, Ethics, Natural Theology, the Principles of Taste, Politics, and last of all, Political Economy, which, from the year 1800, he treated in a separate course. In 1792, appeared his first volume of the *Elements of the Philosophy of the Human Mind*. In 1793, he published his *Outlines*. He read before the Royal Society of Edinburgh, in 1793, his *Account of the Life and Writings of Adam Smith*; in 1796, the *Account of the Life and Writings of Principal Robertson*; and in 1802, the *Account of the Life and Writings of Dr Reid*. In 1805, he took a prominent part in the Leslie controversy; being the author of a pamphlet setting forth the facts of the case, and also, in the General Assembly, giving vent to his indignation at the proceedings against Leslie. In 1806, on the accession of the Whig party to power, he received a sinecure office worth £300 a year. The death of his second son, in 1809, gave a blow to his health, otherwise indifferent, and he was unable to lecture during part of the following session; Dr Thomas Brown, at his request, acting as his substitute. The following year, Brown was appointed conjoint professor, and taught the class till his death in 1820. From 1809, S. lived in comparative retirement at Kinneil House, Linlithgowshire, which the Duke of Hamilton placed at his service. In 1810, he published his *Philosophical Essays*; in 1814, the second volume of the *Elements*; in 1815, the first part, and in 1821, the second part, of the *Dissertation on the History of Ethical Philosophy*; in 1827, the third volume of the *Elements*; and in 1828, a few weeks before his death, the *Philosophy of the Active and Moral Powers*.

On the death of Brown, S. exerted himself to secure the appointment of Sir W. Hamilton to the chair, but the influence used with the Town Council in behalf of John Wilson was overpowering; the votes stood 21 for Wilson, 9 for Hamilton. S. resigned his conjunct professorship on the 20th June 1820.

The philosophy of S. was the following up of the reaction commenced by Reid against the sceptical results that Berkeley and Hume drew from the principles of Locke. Both Reid and S. professed the Baconian method of observation and induction, as against mere ontology, but considered that these processes of investigation could establish certain ultimate truths of a higher certainty than themselves. Hence arose the principles of common sense of Reid, in which S. for the most part acquiesced. S. also followed and improved upon Reid in that systematic exposition of all the powers of the mind, which rendered mental philosophy for the first time a subject of study, independent of metaphysical, logical, and ethical applications; although he also followed it out in all these directions with his usual perspicacity and felicity of exposition. His contributions to the philosophy of Taste, in the *Philosophical Essays*, are among the best parts of his writings.

On the whole, although S. was not one of the most original thinkers in his department, yet, by the force of his teaching and the compass of his writings, he did more than almost any man to diffuse an interest in the speculations connected with the human mind. His collected works have been edited by Sir W. Hamilton, in 11 vols., to which Professor Veitch has contributed his biography.

STEW'ARTON, a town of Scotland, county of Ayr, on the right bank of the Annock, five miles north-west of Kilmarnock, and nominally a station on the Glasgow and South-Western Railway, although the place called *S. Station* is several miles distant from the town. S. owes its prosperity to its woollen and Scotch bonnet manufactures; but it also carries on a variety of minor industries, such as carpet-weaving, Ayrshire needle-work, and the making of spindles for mills. Pop. 3145.

STEW'ARTRY, the name which was given in Scotland to a district governed by a steward, an officer appointed by the king with jurisdiction over crown-lands, and powers similar to those of a lord of regality. While the civil jurisdiction of a steward was equivalent to that of a sheriff, his criminal

jurisdiction was much more extensive. The only remaining trace of this jurisdiction exists in the term stewartry, which in place of county is applied to the district of Kirkcudbright. Galloway was in early times rather a tributary dependency of Scotland than an integral portion of the kingdom, and retained its old Celtic proprietary, and peculiar laws and usages, which were adverse to the introduction of a sheriffdom. It was for a long time ruled by a line of lords, who were among the most powerful feudatories of the Scottish crown. The Comyns, who in the course of time succeeded to the lordship, were overthrown and expatriated by Bruce; and it seems to have been on their forfeiture that Eastern and Central Galloway were erected into the present stewartry, Western Galloway being already under the jurisdiction of the sheriff of Wigton. On the abolition of heritable jurisdictions in 1747, various regalities and baronies which had existed within the district were done away with, and the emancipated stewartry was placed under a steward-depute, whose functions were in every practical point of view the same as those of a sheriff-depute. Act 1 Vict. c. 39, declares that in any existing or future statute the words sheriff, sheriff-clerk, &c. shall be held to apply to steward, steward-clerk, &c.

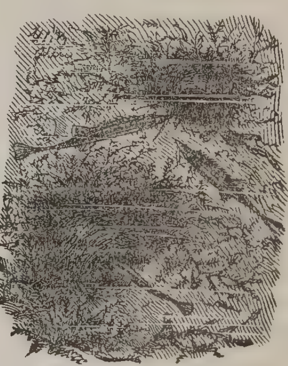
STEWING, in Cookery, a very economical way of preparing meat and fruits for food. It differs from boiling in this respect, that only a small quantity of water is used, and the heat applied is so gentle as only to *simmer* it. A stew-pan should be well fitted with a lid, and the more slowly the ebullition is carried on the better. As the small quantity of water is retained as gravy, nothing is lost. Meat prepared in this way is tender and savoury, but, owing partly to the richness of the gravy, is not very digestible.

STEY′ER, a town of Upper Austria, at the confluence of the Steyer and the Enns, 23 miles south-east of Linz. It is a great seat of the iron and steel manufactures of Austria, and also carries on important manufactures of paper, woollens, and hosiery. Pop. 10,600.

STHAVIRA (a Sanscrit word, meaning *old*) is, in Buddhist hierarchy, the name of the 'elders' or 'venerables,' who, after the death of *the* Buddha S′âkyamuni, taught the doctrine, presided at the Buddhist assemblies, &c., and, since the time of As′oka, were invested with a kind of episcopal power. In the sectarian history of Buddhism, Sthavira is the name of those Arhats who did not follow the schism of the Mahâsânghikas (q. v.), but adhered to the old doctrine. According to another account, the Sthaviras are one of the four divisions of the Vaibhâshika system of Buddhism, and claim for their founder Kâtyâyana, the disciple of S′âkyamuni.—See C. F. Koeppen, *Die Religion des Buddha* (Berlin, 1857); and W. Wassiljew, *Der Buddhismus, seine Dogmen, Geschichte und Literatur* (St Petersburg, 1860)

STICKING-PLASTER, or COURT-PLASTER, is best prepared in the following manner: Two solutions are first made, one of an ounce of isinglass in eight ounces of hot water, and the other of two drachms of gum-benzoin in two ounces of rectified spirit. These solutions are to be strained and mixed. Several coats of this mixture, kept fluid by a gentle heat, are then to be applied with a camel's-hair brush to a piece of black silk stretched on a frame, each coat being allowed to dry before the next is applied. A layer of a solution composed of one ounce of Chian turpentine in two ounces of tincture of benzoin, is then to be applied to the other side of the silk, and allowed to dry. In place of the ordinary black sticking-plaster, some persons prefer colourless plaster, or *Gold-beater's Skin* (q. v.).

STI′CKLEBACK (*Gasterosteus*), a genus of acanthopterous fishes, with ventral fins, abdominal, belonging to the order *Hemibranchii* (Cope), with the *Centriscidæ*, *Fistulariidæ*, etc., and to a distinct family (*Gasterosteidæ*), in which the first dorsal fin is represented by a number of detached spines, a single strong spine occupies the place of the ventral fins, there are only three branchiostegal rays, the gill-covers are not armed, and the body is mailed by plates on the lateral line, and destitute of scales. The species are found in fresh and brackish waters, and in the sea, in cold and temperate regions; and are small fishes, very interesting from their habits and the beauty of their colours, which they change in a remarkable manner, partly according to the colours of surrounding objects, and partly through the influence of their own passions. The THREE-SPINED S. (*G. aculeatus* or *trachurus*), having three spines instead of the first dorsal, is extremely abundant in rivers, ponds, and brackish waters in most parts of Britain and of Europe, and is sometimes also found in the sea. Sticklebacks caught in a river readily accommodate themselves to living in a salt-water aquarium. It seldom exceeds two inches and a half, or three inches in length. Cuvier and Valenciennes, Yarrell, and others distinguish from this several other species, some of which are also



Sticklebacks and Nests.

British, differing in size, the armature of the sides, and other particulars (4 to 15 spines); but some naturalists are still inclined to regard them as mere varieties. The common fresh-water species are sometimes so abundant in ponds, ditches, and the still parts of rivers, as in Lincolnshire and other flat parts of the east of England, that they are used for manure. They are seldom used as food, yet they are said to be excellent for this purpose. Oil has sometimes been expressed from them. In the aquarium, or in their native waters, their combats are very amusing. They are excessively pugnacious, particularly at the breeding season. The larger often devour the smaller, and they destroy the fry of fishes to a prodigious extent; they feed also on aquatic larvæ, and are probably of great use in preventing the excessive multiplication of many kinds of insects. Their nest-building is particularly interesting, and in them nest-building was first observed among fishes. They collect small pieces of straw or stick, with which the bottom of the nest is laid among water-plants, and these they cement together by an exudation from their own bodies, which forms a thread through and round them in every conceivable direction. The thread is whitish,

fine, and silken. The sides of the nest are made after the bottom. The nest of the Fresh-water S. is about the size of a small hazel nut. The eggs, about the size of poppy-seeds, are deposited within. The male makes the nest, into which he introduces the female for the laying of the eggs, and he afterwards watches it with great care—a care not unnecessary, as the eggs are most acceptable food to any other S. which can get at them.

STIFF-NECK (known also as WRY-NECK or TORTICOLLIS) is the term commonly applied to a condition of the neck in which lateral movement of the head causes great pain, and which is due to rheumatism of the muscles lying on the side of the neck, especially the sterno-mastoid. In the great majority of cases, only one side of the neck is affected, the head being drawn more or less obliquely towards that side; but occasionally both sides are equally attacked, in which case the head is kept stiffly erect and looking straight forwards. As long as the head is allowed to remain at rest, there is merely a feeling of discomfort; but every movement is extremely painful. This affection is usually caused either by exposure of the part affected to a current of cold air, or by wearing wet or damp clothes round the neck. In addition to the ordinary treatment of sub-acute Rheumatism (q. v.), heat may be advantageously employed, either, as suggested by Dr Wood of Philadelphia, by placing a batch of carded tow or cotton over the part, and then applying a hot flat-iron, or by the direct application of a small heated iron hammer, as recommended by Drs Corrigan and Day. For the method of applying this hammer, and for cases illustrative of its use, the reader is referred to the last-named physician's memoir, *On the Thermic Treatment of Lumbago and other Forms of Muscular Rheumatism.*

STIGMA. See PISTIL.

STIGMARIA, the root of Sigillaria (q. v.).

STIGMATISA'TION (Lat. *stigmatizatio*, a puncturing, from Gr. *stigma*, a puncture), the name applied, by the mystic writers of the Roman Catholic Church, to the supposed miraculous impression on certain individuals of the 'stigmata,' or marks of the wounds which our Lord suffered during the course of his Passion. These stigmata comprise not only the wounds of the hands and feet, and that of the side, received in the crucifixion, but also those impressed by the crown of thorns and by the scourging. The impression of the stigmata, being held to be miraculous, was regarded as a mark of the signal favour of our Lord, manifested to those who were specially devoted to the contemplation of his Passion. The most remarkable example of stigmatisation is that already referred to in the memoir of FRANCIS OF ASSISI (q. v.), which is said to have occurred on the mountain of Alverno, upon the 15th September 1224, two years before the death of Francis. Being absorbed, according to the account of his biographers, in profound and rapturous contemplation of the Passion of Christ, he saw, as it were, a seraph with six shining wings, blazing with fire, and having between his wings the figure of a man crucified, descend from heaven, and approach him, so as to be almost in contact. After a time, the vision disappeared, but left the soul of Francis filled with reverence and awe; and on his return to calmer thought, he became aware that his body had received externally the marks of the crucifixion. His hands and feet seemed bored through with four wounds, and these wounds appeared to be filled with nails of hard flesh, the heads of which protruded and appeared upon the palms of his hands, and on the instep, while the points protruded upon the opposite side, and seemed as if clenched with a hammer. His side, moreover, presented a red wound, as though from the point of a lance, and this wound occasionally gave forth blood. These mysterious marks continued, and were frequently seen by St Bonaventure and others during the two years which intervened between this date and the death of Francis; and they were seen by multitudes after his death.

It would be out of place here to enter into any discussion as to the origin, or the nature, of this strange phenomenon. But the case of Francis of Assisi is by no means a solitary one; very many others, women as well as men, are recorded as having received all or some of the stigmata. The cases of women so visited are more numerous than those of men. A very remarkable one is that of Veronica Giuliani, in 1694, who is related to have received first the marks of the crown of thorns, and afterwards those of the crucifixion; Gabriella da Piezolo of Aquila is recorded to have received the mark of the lance in 1472; Clara di Pugny, a Tertiary of the Dominican order, was similarly impressed in 1514; and Cecilia di Nobili of Nocera in 1655. Catherine di Raconisio is alleged to have been marked with the crown of thorns in 1583, and the same is related of several others, as Maria Razzi of the island of Chio, Maria Villani, Vincenza Ferreri of Valencia, and Joanna Maria of the Cross, a nun of St Clare, at Roveredo. In some cases, the visitation, although said to be accompanied with excruciating pain in the seat of the several wounds, was unattended by any external marks. Such was the case of St Catherine of Siena, of Ursula Aguirre —otherwise known as Ursula of Valencia—of Mary Magdalen di Pazzi, and of Mechtildis von Stanz; while in other cases the wounds were in part visible, and in part invisible. Thus, Hieronyma Carvaglio suffered the pain of the wounded hands and feet without any external mark, while the lance-wound was not only visible in her side, but was reported to bleed upon every Friday, the day specially devoted to the commemoration of the Passion. Blanca de Gazeran experienced the sensation of pain in the seat of each one of the wounds, but the mark of the nail was visible upon the right foot only. The same variety of sensation is recorded in several other cases.

Most of the cases recorded hitherto are of females; and that examples of these are not wanting even in more recent times, the case of the well-known 'Estatica' of Caldaro, which was the subject of discussion about 25 years ago, sufficiently attests. But, besides that of Francis of Assisi, instances are also recorded in which men were reputed to have received the stigmata. A Capuchin named Benedict, of Reggio, is said to have received the marks of the crown of thorns in 1602. A lay-brother named Carlo di Saeta, or Sazia, was smitten in a vision with the wound in the side. Angelo del Paz, a Franciscan of Perpignan, is related to have borne for many years all the stigmata, as also a Premonstratensian monk named Dodo, and a Franciscan called Nicholas of Ravenna. Several cases also are mentioned of men, who, without the visible or external stigmata, experienced at regular intervals the painful sensation by which the stigmata are accompanied. Many such cases are detailed by the celebrated German mystic, Görres, in his *Christliche Mystik*, vol. ii. pp. 420—456.

STILAGINA'CEÆ, a natural order of exogenous plants, allied to *Urticeæ*, containing about twenty known species of trees and shrubs, natives of the East Indies, Mauritius, and Madagascar. None of them are of importance.

STI'LBITE. See ZEOLITE.

STILICHO, a celebrated Roman general, the mainstay of the Western Empire after the death of Theodosius (q. v.) the Great, is said to have been a Vandal, and was the son of a captain of barbarian auxiliaries of the imperial army. He rose through his military talent to high rank in the army, and Theodosius was so pleased with his rare ability, zeal, and accomplished manners, that he gave him his niece Serena in marriage. S.'s promotion was, however, viewed with great jealousy by Rufinus, the able but evil-minded and ambitious minister of Theodosius, and an inextinguishable feud arose between the two, which it required all the weight of the emperor's influence to repress. In 394, S. departed for Rome in charge of the youthful Honorius (q. v.), who had been committed to his care, placed him on the throne of the Western Empire, and administered in his name the affairs of state. On the death of Theodosius, towards the close of 394, the quarrel for supremacy between S. and Rufinus, the guardian of Arcadius (q. v.), became fully developed, and Alaric (q. v.), at the instigation of the latter, invaded Greece while S. was engaged in chastising the invaders of the Roman territories on the Rhine and in Gaul. S., on his return, at once set out for Constantinople, and put an end to the struggle between himself and Rufinus by the destruction of his rival in 395. He then marched against Alaric, blocked him up in the Peloponnesus, but, through over-confidence, permitted him to escape across the isthmus with his captives and booty. In 398, his daughter Maria became the wife of Honorius. His old opponent, Alaric, after several inroads upon the eastern provinces of the Western Empire, now invaded Northern Italy, but was signally defeated at Pollentia (March 403) by S., who had hurriedly called in the Roman legions from Rhætia, Gaul, Germany, and even Britain. He was again defeated at Verona, upon which he retired from the empire, and S. obtained the honour of a triumph and a great increase of influence and power. S.'s ambition now led him to attempt the introduction of his own family to the imperial succession (a statement disbelieved by Gibbon, who considers it merely as an invention of the crafty Olympius; though the great historian of the Roman Empire honestly confesses to various heavy blots on the character of his hero), by the marriage of his son with the heir-presumptive Placidia, the daughter of Theodosius, and to attain this end, he made overtures of alliance to Alaric, which were gladly accepted. But the dreadful inroad of Radagaisus, in 406, at the head of more than 200,000 (some say 400,000) barbarians, who ravaged the whole country as far as Florence, compelled the great general of the West to shelve for a time his ambitious schemes. With a small but chosen army of veterans, aided by a body of Huns under Uldin (father of Attila), and of Visigoths under Sarus, he so harassed the invaders, that they were forced to give him battle. They were soon routed. Radagaisus, who surrendered, was put to death, and his followers sold as slaves. S. again resumed his pet scheme; established enmity between Rome and Byzantium by seizing on Eastern Illyricum and inducing Alaric to transfer his allegiance to Honorius. But Honorius, who had been prejudiced against S. by one of his officers, Olympius, refused to take Eastern Illyricum from the Byzantine Empire; and subsequently, by an artful harangue, he so influenced the soldiers of the army of Gaul, that they rose *en masse* against the partisans of Stilicho. S. himself was at Bologna; and on the news of the *émeute*, his most zealous friends urged immediate action against Olympius and the Pavian rebels; but for the first time in his life, vacillation seized S., and he declined. They then, for self-preservation, turned against him, and one of them, Sarus, the Goth above mentioned, drove him out of his camp, and compelled him to flee to Ravenna, where he was soon afterwards slain, 23d August 408. Thus perished the last of the series of distinguished aliens, who, as emperors, warriors, or politicians, had propped up the Roman Empire for 150 years, with a stern and resolute zeal equal to that of the early Romans themselves. After protecting the weak empire from formidable invasion by his own kinsmen, administering its affairs with remarkable ability, moderation, and integrity, and restoring its old heroic glory to the imperial arms, S. received the reward which alone an effete and conceited people can be expected to bestow; and three months after his death, Alaric and his Visigoths were at the gates of Rome.

STILL is the apparatus employed for the distillation of liquids, and consists of the copper boiler or *alembic* (see DISTILLATION), in which is contained the fermented liquor whose vapours are to be distilled; of the *neck* or *head*, a pipe which conveys the vapour generated in the boiler into the worm; and of the *worm*, a coiled metal tube which is packed in a vessel called a *refrigeratory*, fitted up in such a manner that the cold water which is poured in at the top comes in contact as extensively as possible with the outside of the tube, and exercises a condensing action upon the vapour which it contains. The vapour thus condensed in its passage through the worm, makes its exit in drops, or in a small stream, into a vessel called the *recipient*, and may be redistilled or not as is required. The various forms of stills are extremely numerous, almost each species of spirit possessing its own form of still, but they all conform to the general description above given.

STILLINGFLEET, EDWARD, Bishop of Worcester, was born April 17, 1635, at Cranbourne, in Dorsetshire. He received his early education at the grammar-school of his native place, and in 1648 became a student at St John's College, Cambridge. He took his degree as Master of Arts; and in 1653 succeeded in obtaining a Fellowship. For some years after leaving college, he was occupied as a private family tutor; and in 1657 he was presented to the rectory of Sutton. In 1659, he came before the world as an author in the work entitled *Irenicum, or the Divine Right of Particular Forms of Church Government examined.* The views here maintained savoured somewhat more of latitudinarianism than could be pleasant to the High Church party, and he afterwards saw reason to modify them. His next performance was the *Origines Sacræ, or Rational Account of the Christian Faith, as to the Truth and Divine Authority of the Scriptures*, a work which made his reputation, and is still had in estimation as one of the most masterly treatises extant on the subject of which it treats. In 1664, appeared his *Rational Account of the Grounds of the Protestant Religion*, a defence of the Church of England from the charge of schism in its separation from that of Rome, which was received with great favour, and led to the preferment of its author. In 1665, the Earl of Southampton presented him to the rectory of St Andrews, Holborn; he was also appointed preacher at the Rolls Chapel, and shortly after lecturer at the Temple, and Chaplain in Ordinary to Charles II. In 1670, he became, by favour of the king, Canon Residentiary of St Paul's Cathedral, and in 1678, was preferred to be Dean of the same. In the Court of Ecclesiastical Commission instituted by James II., S. declined to act; and after the Revolution of 1688, he received

in final acknowledgment of his services to the Protestant cause, his appointment to the bishopric of Worcester. He died at Westminster on 27th March 1699, and was buried in Worcester Cathedral.

S.'s chief works, besides those mentioned, were the *Origines Britannicæ, or Antiquities of the British Churches*, and a bulky volume entitled *The Unreasonableness of Separation*, in reply to an attack made upon him by Howe and others. Throughout, he was besides almost constantly engaged in religious controversy, on the one hand with the adherents of the Church of Rome, and on the other with the Nonconformists. Of his numerous polemical treatises, however important in their day, it is not here necessary to treat in detail. His collected works, in 6 vols. folio, were published in 1710; and in 1735, a supplementary volume of Miscellanies was issued by his son, the Rev. James Stillingfleet, Canon of Worcester. S., though keen and unsparing in conflict, was a good and amiable man, and his unquestioned piety and honesty of intention commanded throughout the respect even of his bitterest opponents.

STILL-LIFE is the name applied to that branch of art which concerns itself with the representation of lifeless objects, such as dead animals, fruits, flowers, vases, and house-furniture.

STILTED ARCH, an arch in which the impost moulding is placed at some distance below the springing of the arch.

STI'MULANTS may be defined to be agents which produce a sudden but not a permanent augmentation in the activity of the vital functions. They give increased energy to the circulatory and cerebro-spinal nervous systems, the primary effect being probably on the nervous system, while the circulation is only secondarily affected. In their mode of action they resemble Tonics (q. v.) in some respects; thus immediately after their administration a feeling of increased power is produced, which, however, is not permanent, and is almost always followed by a corresponding depression of vital power; their effects are, however, more immediate than those of tonics. Many of these agents, as, for example, alcohol and the ethers, are closely allied to narcotics, their secondary effect, if given in sufficiently large doses, being to produce sleep, and even coma. The following are the most important of the general stimulants. 1. *Alcohol*, in the various forms of spirits and wines. As a stimulant, alcohol is employed in medicine to support the vital powers in the advanced stages of fevers, particularly those of a low or typhous character; and it is of service in flatulent colic, in some forms of indigestion, in vomiting, and in fainting. Its almost universal use in inflammatory diseases occurring in persons of broken-down constitution, has recently been advocated by a special school, of which the late Dr Todd may be considered the representative. In cases of severe uterine hæmorrhage and in some forms of fever, it may be given in very large quantity. According to Neligan, in the fever which proved so fatal to the British Legion in Spain in the year 1835, some of the physicians prescribed as much as 32 ounces of brandy (a pint and a half) in 24 hours. 2. *Ammonia*, either in the form of *Solution of Ammonia*, or *Liquor Ammonia*, or as *Carbonate of Ammonia*, is a general stimulant, whose action is rapid, but temporary. It is of special use in the advanced stages of continued fever, in the eruptive fevers when the rash has receded (especially in scarlatina), and in the later stages of pneumonia. It is the best internal stimulant to employ in profound intoxication, and in cases of poisoning by sedatives; and as an external stimulant, the vapour is inhaled in cases of fainting. The solution (which must not be confounded with the *Strong Solution of Ammonia*) may be given in doses of from 5 to 30 minims, diluted with two ounces of water, mucilage, or any bland fluid. The *Carbonate* (formerly known as the sesquicarbonate, which, in reality, it is) may be given in doses varying from 3 to 10 grains in pills or in cold water. The *Aromatic Spirit of Ammonia*, containing both ammonia and its carbonate, is an excellent and agreeable stimulant in fainting, hysteria, flatulent colic, &c., in doses of from half a drachm to a drachm, taken in water or camphor mixture. 3. *Cajeput Oil*, in doses of from 2 to 6 drops on a lump of sugar, or rubbed up with sugar, is a powerful diffusible stimulant, admirably suited for cases of flatulent distention of the stomach and intestines. 4. *Ether* (known also as *Sulphuric Ether*) acts as a general diffusible stimulant; but its effects, which are rapidly produced, are very transient. It is chiefly employed as a stimulant in spasmodic and nervous affections unaccompanied by inflammation, as 'in cramp of the stomach, in spasmodic or flatulent colic, in nervous palpitations, in hiccough, in nervous headache, during a paroxysm of spasmodic asthma, in aphonia, &c. It is also administered frequently with good effect in the advanced stages of fever, when the twitching of the muscles, known as *subsultus tendinum*, and hiccough are present; and as an immediate stimulant in fainting and asphyxia.'—Neligan's *Medicines*, &c., 6th ed., p. 452. It is usually given in doses of about a drachm in some aromatic water. To these more important stimulants may be added camphor, ginger, horse-radish, the preparations of lavender, of the mints &c. It must not be forgotten that electricity, galvanism, and magnetic electricity operate on the animal system either as general or local stimulants, according to the manner in which they are applied. See ELECTRICITY, MEDICAL.

STING-FISH. See WEEVER.

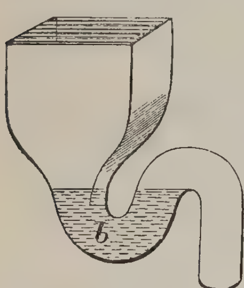
STING RAY (*Trygon*), a genus of cartilaginous fishes, of the order *Raiæ* (see RAY), and family *Trygonidæ*. In this family, the tail is long and slender, the eyes on the upper (dorsal) aspect, and in the genus *Trygon* the tail is armed with a strong spine notched on both sides. The tail has either no fin, or a merely rudimental one. Only one species of S. R. occurs in the British seas (*T. pastinaca*), popularly known as the Fire Flaire. It is found in the Mediterranean, and thence to the

Sting Ray (*Trygon pastinaca*).

northernmost parts of Europe. It resembles a skate in general appearance. The flesh is remarkable for its redness of colour, and is not esteemed. The S. R. is dreaded from the power which it has of using its muscular and flexible tail as a weapon, twisting it round the object of attack, and inflicting severe lacerated wounds with the serrated spine. These wounds often cause great inflammation, whence a notion has been prevalent from ancient times that the sting is charged with venom; but of this there is no evidence. Other species of S. R. are plentiful in the warmer parts of the world, and they are everywhere dreaded. The spine is used by the savages of the South Sea Islands to point their spears.

STINKPOT, in Warfare, a shell, often of earthenware, charged with combustibles, which, on bursting, emit a foul smell and a suffocating smoke. It is useful in sieges for driving the garrison from their defences; also in boarding a ship, for effecting a diversion while the assailants gain the deck. The stinkpot is a favourite weapon of the Chinese. Under the more elegant title of Asphyxiated Shell, the French and other modern nations have experimented considerably on this mode of harassing an enemy.

STINKSTONE, or SWINESTONE, a kind of marble or limestone remarkable for the fetid urinous odour which it emits when rubbed. It contains a little sulphur.



Stink-trap.

STINK-TRAPS, a name given to certain very useful forms of drain-openings, which, whilst allowing liquids to run down, prevent the escape of noxious gases. They are made of iron or earthenware, in a great variety of forms, but on one very simple principle, there being a curved or siphon pipe below the grating or grid (fig.), which always retains sufficient water, *b*, to prevent the outward passage of the gases.

STINK-WOOD (*Oreodaphne fœtida*), a tree of the natural order *Lauraceæ*, a native of the Cape of Good Hope, remarkable for the strong disagreeable smell of its wood, which, however, is hard, very durable, takes an excellent polish, and resembles walnut. It has been used in ship-building.

STINT. See SANDPIPER.

STI'PA. See FEATHER GRASS.

STIPE, in Botany, a term used to designate the stem of palms and tree-ferns.

STI'PEND, the provision for the support of the parochial clergy of the Church of Scotland. It consists of payments in money or grain, or both, made out of the teinds or tithes of their parishes. The Teinds (q. v.), originally the tenths of the produce of the lands drawn in kind, have become converted into a separate estate, held under a liability for stipend. In a majority of cases, they have been purchased at a valuation by the owners of the lands to which they belong, stipends having first been 'modified' from them, and they are held under the burden of augmenting the minister's stipend to the extent of their value. Sometimes they have passed into the hands of titulars, i. e., grantees from the crown and their successors, or belong to colleges and hospitals, to all of whom payment of tithe is made by the proprietor of the lands according to a valuation or composition; and the teinds formerly held by bishops or other dignified clergy are in the hands of the crown. In 1617, a commission was appointed by James VI. to modify stipends to the clergy from the parochial teinds. The provision was at first limited to a maximum of 10 chalders of victual or 1000 merks (£55, 11*s.* 1*d.*) *per annum*, and a minimum of five chalders or 500 merks (£27, 15*s.* 6*d.*); but the minimum was raised in 1649 to eight chalders, or three chalders and money for the other five, at a conversion not exceeding £100 Scots or beneath 100 merks for each chalder; and it has been the practice to allow a further sum to the minister to meet the expense of communion elements. The power of assigning, modifying, and localling stipends has, since the Union, been possessed by the judges of the Court of Session, sitting as a Court of Commission of Teinds. When the existing stipend of a clergyman is considered insufficient, and there remains any free teind (i. e., teind as yet unappropriated for stipend), the court have it in their power to award him out of it what augmentation they deem suitable. But by act 48 Geo. III. c. 138, no stipend can be augmented a second time till after the lapse of 20 years from a previous augmentation. The augmented stipend is modified in victual; but the minister receives it not in kind, but in value, according to the highest fiars (q. v.) prices of each year. By 50 Geo. III. c. 84, £10,000 annually was set apart from the revenue for the purpose of raising all stipends to £150, where the teinds of the parish did not provide that sum. Act 5 Geo. IV. c. 72 makes certain provisions out of the public revenue for those clergymen who have neither manse nor glebe, or who have a manse but no glebe, or a glebe but no manse, and whose stipends do not exceed £200 a year.

The terms at which stipend is payable are Whitsunday and Michaelmas. If the incumbent be admitted before Whitsunday, he is entitled to the whole year's stipend; and if his interest cease before that term, he has no claim to any part of it. If he is admitted between Whitsunday and Michaelmas, he is entitled to a half-year's stipend. If his interest cease between these terms, he or his representatives have right to a half-year's stipend; and if it cease after Michaelmas, to the whole year's stipend. No stipend is due till collation have taken place; and stipend continues due to a suspended clergyman. On the decease of a clergyman, a sum equal to a half-year's stipend is due to his executors, under the name of *ann* or *annat* (a word derived from the not altogether analogous *annatæ*, or first-fruits of the canon law), one half of which goes to the widow, and the other half to the children or other next of kin, the whole passing to the next of kin where there is no widow. It is additional to the sum otherwise due to the incumbent; so that, if he survive Whitsunday, he will have half the year's stipend, and his executors will have the other half as *ann*; and if he survive Michaelmas, he will have the whole year's stipend, and an additional half-year's stipend will be due to the executors as *ann*. The stipend accruing during a vacancy was formerly at the disposal of the patron of the parish for pious uses; but has been given by statutes 50 Geo. III. c. 84, and 54 Geo. III. c. 49, to the Ministers' Widows' Fund.

STIPULATION, in Roman Law, was an agreement attended with certain solemnities.—The word is used in English and Scotch Law only in a popular sense, to denote any distinct matter expressly agreed upon by the parties to an agreement or deed.

STI'PULE, in Botany, a leafy appendage at the base of the leaf-stalk in many plants. Sometimes the stipule is solitary; but frequently there are two, one on each side of the leaf-stalk. They are of very various form and character, often very dissimilar to the leaf with which they are connected. In some plants, they are large, enveloping the young leaf, but soon falling off; in many, they are deciduous; but in many they are as permanent as the leaf itself. Their presence or absence, their deciduous or persistent character, and other peculiarities which they exhibit, form distinctive characteristics not only of species and genera, but of natural orders. They are generally green, like leaves; but sometimes membranaceous. In some plants, they assume the form of spines; in *Cucurbitaceæ*, that of tendrils. Organs of the same nature with stipules appear at the base of the leaflets of some compound leaves.

STI'RLING, a market-town, river-port, and royal, parliamentary, and municipal burgh, capital of the county of the same name, stands on the south bank of the Forth, 29 miles north-east of Glasgow by railway. Like Edinburgh, to which city it bears, in its main features, a striking resemblance, it no doubt owes its origin to the strong natural fortress of its Castle Hill. From this Hill, covering the declivity which slopes north and eastward to the plain, extends the oldest part of the town, around which are numerous streets; while many villas have arisen in the environs. The Castle Hill, which rises gradually from the east, and fronts the west with a steep, precipitous wall of basaltic rock, overlooks the beautiful and fertile *carse*, or flat, which lies along the banks of the Forth. Among the more prominent public buildings and institutions are the East and West Churches—the former erected by James IV. about 1494, the latter built at a later period; and 'Mar's Work,' an incomplete structure, built by the Earl of Mar, Regent of Scotland, who died in 1572, when the building was in progress. This architectural fragment is richly ornamented. In the more ancient quarters, one or two pleasing specimens of old Scotch domestic architecture may still be seen. Of these, 'Argyle's Lodging,' with its pinnacled round towers and decorated windows, is the chief. It is now used as a military hospital. The town-house is surmounted with a spire, and has the old jail attached. It contains the jug or standard of dry measure which was given to the keeping of S. by the Scottish parliament; while Linlithgow is said to have received the firlot; Edinburgh, the ell; Perth, the reel; and Lanark, the pound. The new jail is a handsome and strong building. Cowan's Hospital, founded in 1639, is an object of interest. There are also an Athenæum, Corn Exchange, and numerous excellent schools. The importance of the part which S. played in early times, was due to its situation and its defences. Standing at the head of the navigation of the Forth, when no regular ferries crossed that river, S. was the key to the Highlands; and the possession of its strengths and its means of communication between north and south was of the greatest importance. The town, besides, was strongly fortified both by nature and art. The ancient bridge of S., the age of which is unknown, but which was in existence in 1571, is composed of four arches, and was defended at each end by gates and towers. This bridge was, until quite recent years, the only one by which wheeled carriages could cross the Forth. Vessels of 150 tons can reach the port of S.; but its commerce by river is now of less importance than before the days of railways. S. is a central railway station, and the means of communication in every direction are ready and abundant. The rich agricultural, mining, and manufacturing districts around are to a great extent the basis of the prosperity of the town itself. Manufactures of ropes, malt, leather, soap, and mineral oils are carried on. The town unites with the Dunfermline burghs in sending a member to the House of Commons. Pop. (1861) of parl. burgh, 13,716; of town, 10,873; of parl. burgh (1881) 16,013.

S. (formerly *Stryvelyne*, or *Estrivelin*) is one of the most ancient and historically important towns of Scotland. It is of unknown antiquity; and there is no record from which the date of the foundation of even the castle can be determined. It must have been a frontier fortress from the earliest times. Alexander I. died in the castle in 1124. In the vicinity, the battle of Stirling was fought in 1297. See WALLACE. The town was taken by Edward I., after a siege of three months, in 1304. In the vicinity, at Bannockburn (q. v.), the famous battle of that name was fought in 1314. The castle was the birthplace of James II. and of James V. James III. built the Parliament House in the Castle, and otherwise improved and embellished the fortress. James V. built the palace, the walls of which are profusely covered with grotesque ornamentation. In the older part of the Castle is the 'Douglas Room,' in which William, Earl of Douglas, was assassinated by James II. In 1651, after the battle of Dunbar, the castle was taken by Monk; and it withstood a siege by the Highlanders in 1745. The view from the towers of Stirling Castle is unsurpassed in beauty. Westward, the rich vale of Menteith stretches away to the Highlands, where Ben Lomond, Ben Venue, Ben A'an, and Ben Ledi close the scene. The glittering 'links' of Forth are seen in the Carse of Stirling, surrounded by fertile fields and luxuriant woods; the Abbey Craig, crowned by the Wallace Monument, rises boldly on the north; while on the east are seen the picturesque ruins of Cambuskenneth Abbey.

STI'RLINGSHIRE, a county of Scotland, forming the border-land between the Highlands and Lowlands of the country, is bounded on the N. by Perthshire and by the river and Firth of Forth. Area, 462 sq. m.; pop. (1881) 112,443. A considerable part of S. is occupied by the carses of Stirling and Falkirk, which were formerly covered for the most part with unproductive moss. On the removal of the moss-soil, part of which was floated off into the Forth by the agency of running water, a rich clay-soil, of various depths, from a plough-furrow to 20, and even 30 feet, was reached, and is now cultivated with the most marked success. The chief elevation is Ben-Lomond (q. v.), in the north-west. The chief rivers are the Forth (q. v.), the Carron—navigable for small vessels to Carron-shore—and the Endrick. Loch Lomond (q. v.) is the only important lake in the county. S. is remarkable for its mineral stores, especially iron-stone, which is wrought on an extensive scale at Carron (q. v.). Woollen goods, &c., are largely manufactured, especially at Alva, Bannockburn, and in the neighbourhood of Stirling (q. v.). According to the agricultural statistics taken in 1872, there were 1498 occupants. The total acreage under all kinds of crops, bare fallow and grass, was 105,073; the total under corn crops was 32,019; 3889 acres were under wheat; 5006 under barley; 19,322 under oats; 86 under rye; 3710 under beans; 4378 under potatoes; 24,601 with clover and grasses under rotation; 36,501 with permanent pasture and meadow. The returns show that in the same year there were in the county of Stirlingshire 4289 horses, 30,733 head of cattle, 122,024 head of sheep, and 2846 swine. Capital, Stirling.

STI'RRUPS (Naval) are eyes of rope pendent from the yards, and supporting certain portions of the tackle connected with the management of the sails.

STITCH in the side is the popular and expressive name applied to the pain felt in pleurisy. It occupies a point or small spot on a level with, or just beneath, the breast on the affected side; and patients state that they feel as if some sharp stabbing instrument were being driven in at that spot, whenever the act of respiration goes beyond a certain limit. It is termed in French *Point de côté*. See PLEURISY. A simple modification of stitch is by no means uncommon, if a person takes exercise shortly after partaking of a full meal. The pain in this case is seated lower in the side, and is usually removed by stooping. Hence the popular remedy for this pain is to make a cross upon the foot.

STI'TCHWORT (*Stellaria*), a genus of plants of the natural order *Caryophylleæ*, having a calyx of 5 leaves, 5 deeply-cloven petals, 10 stamens, 3 styles,

Greater Stitchwort (*Stellaria Holostea*).

and a many-seeded capsule opening with six teeth. The species are numerous, and several are very common in the United States, annual and perennial plants, with weak stems and white flowers, which in some are minute, and in others are large enough to be very ornamental to woods and hedge-banks, as in the Wood S. (*S. nemorum*) and the Greater S. (*S. Holostea*). To this genus the common Chickweed (q. v.) is now generally referred.

STI'VER, a coin of Holland, equivalent to a penny sterling, being the $\frac{1}{20}$th of a guilder or gulden. See FLORIN.

STOAT. See ERMINE.

STOCK, or STOCK GILLYFLOWER (*Matthiola*), a genus of plants of the natural order *Cruciferæ*, having cylindrical or compressed pods, and a stigma consisting of two upright appressed plates, the outer side of which often rises into a knob or horn. The species are herbaceous or half-shrubby, natives of the countries around the Mediterranean Sea, most of them thickly clothed with white or grayish stellate hairs; the flowers in racemes, and generally beautiful and fragrant. Some of the species have long been much cultivated, and many fine varieties have been produced by cultivation. *M. incana*, a very rare and even doubtful native of England, is probably the parent of the greater number of the cultivated kinds with hoary leaves, known as Brompton S., &c.; whilst those with smooth leaves, called Ten-week S., German S., &c., are referred to *M. annua*, *M. glabra*, and *M. fenestralis*, which, perhaps, are mere varieties of one species. The sandy shores of Wales and of Cornwall produce a species, *M. sinuata*, the large purple flowers of which are fragrant only at night—a characteristic also of several other species. Stocks are always raised by gardeners from seed, which even the double kinds often produce, a multiplication of the petals having taken place without loss of the parts of fructification. Of the seedlings, however, some produce double, and others single flowers, so that only some gratify the cultivator. The hoary-leaved stocks are generally treated as biennials, although, in reality, they may almost be reckoned perennial; and it is not desirable that they should flower in the first year, as the plants become stronger when they remain without flowering till the second year, and produce richer racemes of flowers. The smooth-leaved stocks are treated as annuals.—The beautiful little annual called Virginian Stock does not belong to this genus, although it is of the same natural order. Its habit is indeed very different. It is *Malcolmia maritima*, and notwithstanding its popular name, is a native of the shores of the Mediterranean. It has become one of our most favourite flowers, almost rivalling mignonette, and is all the more esteemed because it grows well in the little garden-plots which are exposed to the smoke of towns.

STOCK-FISH, a commercial name of salted and dried cod and other fish of the same family, particularly the Ling, Hake, and Torsk (see these heads). The fish is cured as soon as possible after being caught. It is split up from head to tail, cleansed from all particles of blood by plentiful washings with salt water; a piece of the back-bone is cut away; and after the superfluous water has drained off, the fish are laid in long vats, covered with salt, and kept down by heavy weights. By and by, they are taken out, washed and brushed, and then exposed to sun and air on a sandy beach or upon rocks. They are afterwards gathered into little heaps, and when they assume a fine whitish appearance, known as the *bloom*, they are considered ready for the market. Great quantities of stock-fish are thus prepared in the northern parts of the world, and are not only used in the countries which produce them, but are largely exported to more southern regions, where they are in great demand. The cod, ling, and hake fishery of Scotland is next in importance to its herring-fishery. The most productive year hitherto was 1863, which, according to the Report of the Fishery Commissioners, yielded 129,725¾ cwts. of dried fish, besides 7963¼ barrels cured in pickle. The quantity of stock-fish cured on the more southern coasts of Britain is inconsiderable.

STO'CKHOLM, the capital of Sweden, is situated at the eastern extremity of the Maelar Lake, in 59° 20′ N. lat., and 18° 5′ E. long. The pop. was in 1879, 173,433. S., which is one of the most beautiful capitals of Europe, is built partly on the continent, and partly on nine holms, or islands, lying in the channel through which the Maelar Lake discharges its waters into the Baltic, about 36 miles distant. The Helge-aand, Stads, and Riddar holms, which formed the nucleus of the ancient city, founded in 1250 by Birgir Jarl, contain some of the finest public and private buildings, among which we may instance the royal palace, built in 1753, in the Italian style, and situated on a hill, commanding a view of the romantic shores of the lake. Near the palace, which possesses good antiquarian, numismatic, and other collections, a library, gallery of paintings, large gardens, &c., is the colossal statue of Gustavus

III., on one of the fine quays which skirt the chief harbour of S.; the cathedral, or St Nicolai's; the Knights' Hall, with the adjoining market, ornamented with the fine statue of Gustavus Vasa, the Council-house, the Riddarsholm Kirke, where all the kings of Sweden since Charles X. have been buried; &c. Among the other public buildings, the most noteworthy are the Observatory, the Church of St James, the College of Surgery, and the Opera-house, with the neighbouring and corresponding palace, in the aristocratic quarter of Norrmalm, which, with the new parade-ground, its public gardens, and its fine wide and even streets, ranks as the handsomest part of the town. The most picturesque of the nine islets of S. is the Södermalm, on whose steep sides the houses, connected more frequently by steps than roads, rise in terraced rows to the even summit, which is crowned by St Catherine's Church. Numerous public gardens, summer palaces, and country-houses extend along the north-east shores of the lake, and on the margins of the Ladugaard's Holm, the central portions of which present a picturesque blending of rocks, wooded heights, and romantic glens. On this side of S. lies the famous Djurgaard, or Zoological Gardens, one of the finest public parks in Europe, which occupies a peninsula two miles long, and one mile wide, whose natural beauties have been judiciously aided by art. Stone and wooden bridges connect together the various islands of the town. The streets of the older quarters are narrow, crooked, and ill paved; but in the better parts of the town there are fine straight streets and capacious squares and open places, with well-built stone houses; while in the suburbs the houses are mostly of wood. S. is the seat of the government, and of the chief courts of law and administration, the residence of the sovereign, and the place of assembly for the legislative chambers. It is the centre of the literary and social activity of the country, and has numerous scientific, artistic, educational, and benevolent institutions. In the immediate vicinity of S. are the Karlsberg Academy, for naval and military cadets; and the Ulriksdal Hospital, for invalided soldiers. No city has more picturesque environs, or more numerous public gardens and walks, than S.; while the many channels and canals connected with its large and commodious harbours facilitate traffic and intercommunication with the interior, and with foreign ports. S. is the principal emporium of Swedish commerce; iron, timber, and deal planks are its main articles of export; but it is also the centre of an active trade in the various manufactures of the place—as, for instance, leather, cotton, woollen, and silk fabrics, glass and porcelain, iron and steel goods, steam-engines, &c., which it sends, together with the ordinary colonial and other imports, to all the other towns of Sweden.

STOCKING-FRAME. The machine with which stockings, singlet drawers, and other similar garments are woven, was first invented by William Lee of Woodbridge, Nottinghamshire. At first, it was a very simple affair, but has now become extremely complicated, although the simple principle upon which it was first originated is retained as the essential. This can only be understood by reference to the art of knitting, which originated it. In knitting, only one thread is used, and this formed into a succession of loops on a knitting-needle; each of these loops, then, has in succession another loop passed through it by means of another and similar needle, and this operation is carried on successively until the whole fabric is made. In the stocking-frame, instead of one needle to hold the stationary loops while those of the moving row are being inserted, there are as many needles as there are to be loops in the breadth of the web, and these are so made as to alternately form and give off the loops. The form of this needle is shewn in fig. 1, and

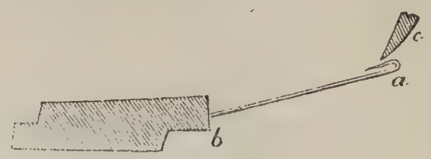


Fig. 1.

fig. 2 shews a front view of its point, in order to exhibit a small indentation, *a*, into which the bent point of the needle *a* (fig. 1), is easily pressed.

Fig. 2.

The other end of the needle is fixed into a small casting of tin, *b* (fig. 1), formed to fit into a frame and be screwed tightly in, side by side with the rest of the needles. Between the needles are placed thin plates of lead or pewter, called *sinkers* (fig. 3)

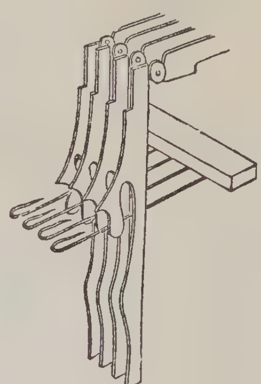

Fig. 3.

in two rows; in one row, the sinkers move freely on an axis (fig. 3); in the other, they are all fixed to a bar, and move with it. The object of the loose ones, or *jack-sinkers*, is to make loops by pressing the thread down between the needles, as shewn in figs. 4 and 5 at *a*. The other row on the bar, or

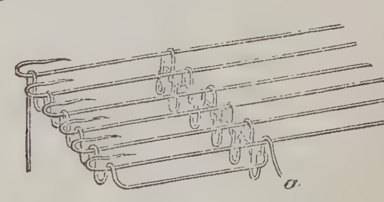

Fig. 4.

lead-sinkers, are brought down, so as to press simultaneously on the hooks of the needles, and press their points down into the little depression *a* (fig. 2), so that they will pass through the loops without catching one way, and take them up when opened and drawn in the contrary direction. The point of the lead-sinker is seen in fig. 1, *c*. These are the

essential parts of a stocking-frame, which contains so vast a number of needles and sinkers, and such nice mechanical arrangements for giving them their

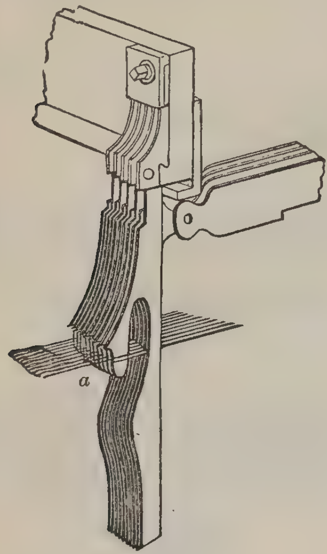

Fig. 5.

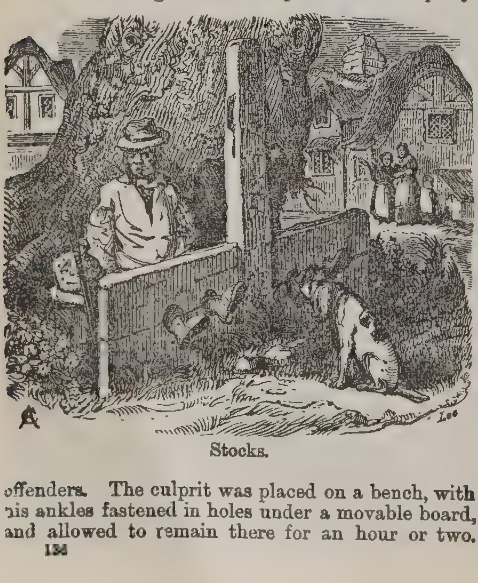
regular movements, that few machines have so complicated an appearance to the observer; and any attempt to extend this description, would only serve to puzzle rather than explain.

STOCKINGS. See HOSIERY.

STO'CKPORT, a town of England, in the county of Chester, on the river Mersey, and 6½ miles south-east of Manchester by railway. It is of great antiquity, but its prosperity is of modern date. S. has extensive manufactures of cottons, woollens, silks, machinery, brass and iron goods, shuttles, and brushes. Pop. about 60,000, who return two members to parliament.

STOCKS, an apparatus of wood, much used in former times in England for the punishment of petty



Stocks.

offenders. The culprit was placed on a bench, with his ankles fastened in holes under a movable board, and allowed to remain there for an hour or two. The period of their first introduction is uncertain, but in the second Statute of Labourers, 25 Edw. III. (1350), provision is made for applying the stocks to unruly artificers; and in 1376, the Commons prayed Edward III. that stocks should be established in every village. Each parish had in later times its stocks, usually close to the churchyard, but sometimes in a more retired spot; and in some country places they are still to be seen, and not altogethe disused. Combined with the stocks was often whipping-post for the flagellation of vagrants.

STOCKS. See FUND.

STO'CKTON, a town and port of entry of California, U. S., on Stockton Channel, near San Joaquin, 130 miles east-north-east of San Francisco. It is an important commercial point, and the entrepôt of the southern gold mines. It has three newspapers, several churches, a hospital, and pop. of 10,066.

STO'CKTON-ON-TEES, a municipal borough and seaport in the county of Durham, 11 miles east-north-east of Darlington, on the left bank of the Tees. The broad and handsome High Street is nearly a mile in length, and from it several minor streets diverge at right angles. A new town, known as South Stockton, has sprung up within the last few years on the right bank of the river. The town contains two churches, a Roman Catholic chapel built by Pugin, several dissenting chapels, an athenæum, and other important edifices. The Stockton Races, of some mark in the sporting world, are held here annually. Ship-building, chiefly in iron, is carried on to a great extent; and blast-furnaces, foundries, engine-works, and extensive potteries and iron-works are in operation. Sail-cloth, ropes, linen, and diapers are manufactured; and there are breweries, corn-mills, and spinning-mills. The exports are chiefly iron and earthenware; the imports are corn, timber in deals, spars, &c., and bark. In 1869, 885 foreign and coasting vessels of 105,701 tons entered and cleared the port, 727 being British and 158 foreign. The town is connected with the whole railway system of England and Scotland by the North-eastern Railway Company's branches, and there are two stations here. The Stockton and Darlington Railway, the first in the United Kingdom to commence passenger traffic, was opened for the double purpose of the conveyance of passengers and goods, September 27, 1825. At S. the Tees is navigable for vessels of large tonnage; the distance from the town to the sea has recently been shortened three miles, the navigation of the river much improved, and great facilities for an extensive trade provided. Pop. (1800) 3666; (1861) 13,357; (1881) 41,040.

S. suffered severely from the incursions of the Scots in the early part of the 14th c., but even at that time it enjoyed considerable trade. It was taken for the Parliament in 1644, and totally destroyed by the Roundheads in 1652. At the Restoration it had become so poor a place that it contained only 120 houses, and most of these were built of clay. Pop. of parliamentary borough (1881) 55,446.

STOICS, the name for the sect of ancient moralists opposed to the Epicureans in their views of human life. The Stoical system dates from the end of the 4th c. B. C.; it was derived from the system of the Cynics, whose founder, Antisthenes, was a disciple of Socrates. Indeed, the doctrines, but still more the manner of life, and most of all the death, of Socrates, were the chief foundations of the Stoical philosophy.

The founder of the system was ZENO, from Cittium in Cyprus (he lived from 340—260 B. C.),

who derived his first impulse from Crates the Cynic. He opened his school in a building or porch, called the *Stoa Pœcile* ('Painted Porch') at Athens, whence the origin of the name of the sect. Zeno had for his disciple CLEANTHES, from Assos in the Troad (300—220 B.C.), whose *Hymn to Jupiter* is the only fragment of any length that has come down to us from the early S., and is a remarkable production, setting forth the unity of God, his omnipotence, and his moral government. CHRYSIPPUS, from Soli in Cilicia (280—207 B. C.), followed Cleanthes, and, in his voluminous writings, both defended and modified the Stoical creed. These three represent the first period of the system. The second period (200—50 B. C.) embraces its general promulgation, and its introduction to the Romans. Chrysippus was succeeded by ZENO of Sidon, and DIOGENES of Babylon; then followed ANTIPATER of Tarsus, who taught PANÆTIUS of Rhodes (died 112 B.C.), who, again, taught POSIDONIUS of Apamea, in Syria. (Two philosophers are mentioned from the native province of St Paul, besides Chrysippus—Athenodorus, from Cana in Cilicia; and Archedemus, from Tarsus, the apostle's birthplace. It is remarked by Sir A. Grant, that almost all the first S. were of Asiatic birth; and the system itself is undeniably more akin to the oriental mind than to the Greek.) Posidonius was acquainted with Marius and Pompey, and taught Cicero; but the moral treatise of Cicero, *De Officiis*, is derived from a work of Panætius. The third period of Stoicism is Roman. In this period we have Cato the Younger, who invited to his house the philosopher Athenodorus; and, under the Empire, the three Stoic philosophers whose writings have come down to us—SENECA (6 B. C.—65 A. D.), EPICTETUS (60—140 A. D.), who began life as a slave, and the Emperor MARCUS AURELIUS ANTONINUS (121—180 A. D.). Stoicism prevailed widely in the Roman world, although not to the exclusion of Epicurean views.

The leading Stoical doctrines are given in certain phrases or expressions, as 'Life according to Nature,' the ideal 'Wise Man,' 'Apathy' or equanimity of mind, the power of the 'Will,' the worship of 'Duty,' the constant 'Advance' in virtue, &c. But perspicuity will be best gained by considering the *Moral* system under four heads—the Theology; the Psychology or theory of mind; the theory of the Good or human happiness; and the scheme of Virtue or Duty.

I. Their Theological doctrines comprehended their system of the Universe, and of man's position in it. They held that the Universe is governed by one good and wise God, together with inferior or subordinate deities. God exercises a moral government; under it the good are happy, while misfortunes happen to the wicked. According to Epictetus, God is the father of men; Antoninus exults in the beautiful arrangement of all things. They did not admit that the Deity intermeddled in the smaller minutiæ; they allowed that omens and oracles might be accepted as signs of the foreordained arrangement of God. They held this foreordination even to the length of fatalism, and made the same replies, as have been given in modern times, to the difficulty of reconciling it with Free-will, which in their system was unusually prominent. As to the existence of evil, they offered explanations such as the following: God is the author of all things except wickedness; the very nature of good supposes its contrast evil, and the two are inseparable, like light and dark, which may be called the argument from Relativity; in the enormous extent of the Universe, some things must be neglected; when evil happens to the good, it is not as a punishment, but as connected with a different dispensation; parts of the world may be presided over by evil demons; what we call evil may not be evil.

Like most other ancient schools, the S. held God to be corporeal like man; Body is the only substance; nothing incorporeal could act on what is corporeal; the First Cause of all, God or Zeus, is the primeval fire, emanating from which is the soul of man in the form of a warm ether.

It is for human beings to recognise the Universe as governed by universal Law, and not only to raise their minds to the comprehension of it, but to enter into the views of the Creator, who must regard all interests equally; we are to be, as it were, in league with him, to merge self in the universal Order, to think only of that, and its welfare. As two is greater than one, the interests of the whole world are infinitely greater than the interests of any single being, and no one should be satisfied with a regard to anything less than the whole. By this elevation of view, we are necessarily raised far above the consideration of the petty events befalling ourselves. The grand effort of human reason is thus to rise to the abstraction or totality of entire Nature; 'no ethical subject,' says Chrysippus, 'could be rightly approached except from the preconsideration of entire Nature, and the ordering of the whole.'

As to Immortality, the S. precluded themselves, by holding the theory of the *absorption* of the individual soul at death into the divine essence; but, on the other hand, their doctrine of advance and aspiration is what has in all times been the main natural argument for the immortality of the soul. For the most part, they kept themselves undecided as to this great doctrine, giving it as an alternative, reasoning as to our conduct on either supposition, and submitting to the pleasure of God in this as in all other things.

In arguing for the existence of Divine power and government, they employed what has been called the argument from Design, which is as old as Socrates. Man is conscious that he is in himself an intellectual or spiritual power, from which, by analogy, he is led to believe that a greater power pervades the universe, as intellect pervades humanity.

II. Next, as to the Constitution of the Mind. We have bodies like animals, but reason or intelligence like the gods. Animals have instinctive principles of action; man alone has a rational, intelligent soul. According to Antoninus, we come into contact with Deity by our intellectual part, and our highest life is thus the divine life.

But the most important Stoical doctrine respecting the nature of man is the recognition of Reason as a superior power or faculty that subordinates all the rest—the governing intelligence. (Very nearly the same phraseology is used by Bishop Butler in setting forth the supremacy of Conscience.) This, however, is not a mere intellectual principle, but an active force, uniting intellect and will. The bodily sensibilities are opposed to this higher Reason and Will, which, however, is strong enough to control them. Another way of expressing the same view was the power of the Mind over the Body, which was dwelt upon by Epictetus in the most exaggerated form. The introduction of so glaring a mistake, as that sickness may affect the body without enfeebling the mind, could only end in practical failures, or else in contradiction.

In order to maintain their contrast with the Epicureans, the S. said that pleasure and pain are not principles of Nature; by which they must have meant that humanity is not in fact, at least exclusively, governed by these, and that, in the regenerated man, they are not governing principles at all. Now, it is true, and a truth important for many

practical purposes, that we are sometimes impelled to action without reference to our pleasures and pains; our habits often exemplify this state; it is still better shewn in what are called 'fixed ideas,' as in involuntary imitation and sympathy. But these are exceptions; and any system that sets itself against the main fact, that pleasure and pain are the great moving forces of mankind, must somewhere or other contradict itself.

In Seneca, we find something very closely approaching to the Christian doctrine of the corruption of human nature. The littleness of humanity was a favourite theme of Antoninus, and naturally followed from the Stoical mode of contemplating the Universe at large.

The doctrine called the Freedom of Will may be said to have originated with the S., although with them it was chiefly a rhetorical mode of expressing the dignity of the Wise Man, and his power of rising superior to circumstances.

To prepare the way for the Stoical precepts, Epictetus distinguished between things in our power and things not in our power. The things in our power are our opinions and notions about objects, and all our affections, desires, and aversions; the things not in our power are our bodies, wealth, honour, rank, authority, &c., and their opposites. The application is this: wealth and high rank may not be in our power, but we have the power to form an *idea* of these—namely, that they are unimportant, whence the want of them will not grieve us. A still more pointed application is to death, whose force is entirely in the idea.

III. We must consider next the Stoical Theory of Happiness, or rather of the Good, which with them was not identified with happiness. They began by asserting that happiness is not necessary, and may be dispensed with, and that pain is no evil, which, however, if followed consistently, would dispense with all morality and all human endeavour. Substantially and practically, they held that pains are an evil, but, by a proper discipline, may be triumphed over. They disallowed the direct and ostensible pursuit of pleasure as an end (the point of view of Epicurus), but allured their followers partly by promising them the victory over pain, and partly by certain enjoyments of an elevated cast that grew out of their plan of life.

Pain of every kind, whether from the casualties of existence, or from the severity of the Stoical virtues, was to be met by a discipline of endurance, a hardening process, which, if persisted in, would succeed in reducing the mind to a state of Apathy or indifference. A great many reflections were suggested in aid of this education. The influence of exercise and repetition in adapting the system to any new function. was illustrated by the Olympian combatants, and by the Lacedæmonian youth who endured scourging without complaint. Great stress was laid on the instability of pleasure, and the constant liability to accidents; whence we should always be anticipating and adapting ourselves to the worst that could happen, so as never to be in a state where anything could ruffle the mind. It was pointed out how much might still be made of the worst circumstances—poverty, banishment, public odium, sickness, old age—and every consideration was advanced that could 'arm the obdurate breast with stubborn patience, as with triple steel.'

It has often been remarked that such a discipline of endurance was peculiarly suited to the unsettled condition of the world at the time, when any man, besides the ordinary evils of life, might in a moment be sent into exile, or sold into slavery. Moreover, it is a discipline adapted to a certain class of dispositions existing in all ages—the men that prefer above all things 'equanimity' of mind, and would rather dispense with great occasional pleasures than risk their state of habitual composure.

Next to the discipline of endurance, we must rank the complacent sentiment of Pride, which the Stoic might justly feel in his conquest of himself, and in his lofty independence and superiority to the casualties of life. The pride of the Cynic, the Stoic's predecessor, was prominent and offensive, shewing itself in scurrility and contempt towards everybody else; the Stoical pride was a refinement upon this, but was still a grateful sentiment of superiority, which helped to make up for the surrender of indulgencies. It was usual to bestow the most extravagant laudation on the 'Wise Man,' and every Stoic could take this home to the extent that he considered himself as approaching that great ideal.

The last and most elevated form of Stoical happiness was the satisfaction of contemplating the Universe and God. Epictetus says that we can discern the providence that rules the world, if we possess two things—the power of seeing all that happens with respect to each thing, and a grateful disposition. The work of Antoninus is full of studies of Nature in the devout spirit of 'passing from Nature to Nature's God;' he is never weary of expressing his thorough contentment with the course of natural events, and his sense of the beauties and fitness of everything. Old age has its grace, and death is the becoming termination. This high strain of exulting contemplation reconciled him to that complete submission to whatever might befall, which was the essential feature of the 'Life according to Nature.'

IV. The Stoical theory of Virtue is implicated in their ideas of the Good, now described.

The fountain of all virtue is manifestly the life according to nature, as being the life of subordination of self to more general interests—to family, country, mankind, the whole universe. If a man is prepared to consider himself absolutely nothing in comparison with the universal interest, and to regard it as the sole end of life, he has embraced an ideal of virtue of the loftiest order. Accordingly, the S. were the first to preach what is called 'Cosmopolitanism;' for although, in their reference to the good of the whole, they confounded together sentient life and inanimate objects—rocks, plants, &c., solicitude for which was misspent labour—yet they were thus enabled to reach the conception of the universal brotherhood of mankind, and could not but include in their regards the brute creation. They said: 'There is no difference between Greeks and Barbarians; the world is our city.' Seneca urges kindness to slaves, for 'are they not men like ourselves, breathing the same air, living and dying like ourselves?'

The Epicureans declined, as much as possible, interference in public affairs, but the Stoical philosophers all urged men to the duties of active citizenship. Although there had been many good and noble men among the pagans, yet positive beneficence had not been preached as a virtue before the Stoics. They adopted the four Cardinal Virtues (Wisdom, or the Knowledge of Good and Evil; Justice; Fortitude; Temperance) as part of their plan of the virtuous life, the life according to nature. Justice, as the social virtue, was placed above all the rest. But most interesting to us are the indications of the idea of Beneficence. Epictetus is earnest in his exhortations to forgiveness of injuries. Antoninus often enforces the same virtue, and suggests considerations in aid of the practice of it; he contends as strongly as Butler and Hume for the existence of a principle of pure, that is, unselfish,

benevolence in the mind; in other words, that we are made to advance each other's happiness.

There is also in the Stoical system a recognition of duties to God, and of morality as based on piety. Not only are we all brethren, but also the 'children of one Father.'

The extraordinary stress put upon human nature by the full Stoic ideal of submerging self in the larger interests of being, led to various compromises. The rigid following out of the ideal issued in one of the Paradoxes, namely that all the actions of the wise man are equally perfect, and that, short of the standard of perfection, all faults and vices are equal; that, for example, the man that killed a cock without good reason was as guilty as he that killed his father. This has a meaning only when we draw a line between spirituality and morality, and treat the last as worthless in comparison of the first. The later S., however, in their exhortations to special branches of duty, gave a positive value to practical virtue, irrespective of the ideal.

The idea of Duty was of Stoical origin, fostered and developed by the Roman spirit and legislation. The early S. had two different words for the 'suitable' (*kathēkon*) and the 'right' (*katorthōma*); although it is a significant circumstance that the 'suitable' is the lineal ancestor of our word 'duty' (through the Latin *officium*).

It was a great point with the Stoic to be conscious of 'advance,' or improvement. By self-examination, he kept himself constantly acquainted with his moral state, and it was both his duty and his satisfaction to be approaching to the ideal of the perfect man. When renouncing the position of 'wise,' he yet claimed to be advancing. This idea, familiar to the modern world, was unknown to the ancients before the Stoics. It is very illustrative of the unguarded points and contradictions of Stoicism, that contentment and apathy were not to permit grief even for the loss of friends. Seneca, on one occasion, admits that he was betrayed by human weakness on this point. On strict Stoical principles, we ought to treat the afflictions and the death of others with the same frigid indifference as our own; for why should a man feel for a second person *more* than he ought to feel for himself, as a mere unit in the infinitude of the Universe? This is the contradiction inseparable from any system that begins by abjuring happiness as the end of life. We may be allowed to regard our own happiness as of no importance, but if we apply the same measure to happiness in general, we are bereft of all motives to benevolence; and virtue, instead of being set on a loftier pinnacle, is left without any foundation.

The Stoical system has largely tinctured modern ages, in spite of its severity. It has always had a charm as an ideal, even when men were conscious of not realising it. It may be still considered as a grand experiment in the Art of Living, from which valuable lessons have resulted; just as a believer in Alchemy, or in the Perpetual Motion, might make useful experimental discoveries. The limitation of wants, the practice of contentment, the striving after equanimity, the hardening of one's self against the blows of fortune, are all familiar to the moralists of later ages. A qualified form of the subordination of self to the general welfare, belongs to the modern theories of virtue.

The chief ancient authorities on the Stoics are the writings of Epictetus, Marcus Antoninus, and Seneca, themselves Stoical philosophers, together with notices occurring in Cicero, Plutarch, Sextus Empiricus, Diogenes Laertius, and Stobæus. The completest modern account of the system occurs in Zeller's *Philosophie der Griechen*, vol. iii. See also an article by Sir Alexander Grant in the *Oxford Essays* for 1858.

STOKE-UPON-TRENT, a parliamentary borough, and manufacturing town of Staffordshire, 145 miles from London by the London and North-western Railway. The 'district' of S. consists of the parish, 10,490 acres in extent, is familiarly named the 'Potteries,' and contains the towns of Burslem, Hanley, Lane-End (with Longton), Stoke, and Tunstal Court. The town of S. is regularly built, and contains many modern houses. Its church, an edifice in modern Gothic, is surmounted by a tower 112 feet high. The earthenware manufactures of the parish of S. are carried on in about 200 factories. In the vicinity are numerous coal-mines. Pop. of parliamentary borough, which sends two members to the House of Commons (1881), 152,457; of the town, 19,263.

STOKES, George Gabriel, one of the greatest living mathematicians and natural philosophers in Europe, was born, in 1819, at Skreen, County Sligo, Ireland; educated at the school of the Rev. R. H. Wall, D.D., Dublin; afterwards at the Bristol College. He entered Pembroke College, Cambridge, in 1837; graduated in 1841, as Senior Wrangler, and First Smith's Prizeman; became Fellow of Pembroke in the same year; and was elected, in 1849, to fill, as one of the worthiest of Newton's successors, the Lucasian Chair of Mathematics in Cambridge. In 1854, he was appointed Secretary to the Royal Society.

He is best known, popularly, by his beautiful discovery of Fluorescence (see Phosphorescence). His paper *On the Change of the Refrangibility of Light*, is printed in the *Philosophical Transactions* for 1852—1853. His recent important physiological application of optical methods to the study of the oxidation of the blood, is noticed under Spectrum. But to mathematicians and natural philosophers, S. is known by a number of admirable papers in the *Cambridge Philosophical Transactions*, the *Cambridge and Dublin Mathematical Journal*, and the *Philosophical Magazine*. In them he has greatly extended and improved the mathematical treatment of questions connected with the distortion of elastic solids, the motion of waves in water, the undulatory theory of light, the summation of series, the internal friction of fluids, &c. But to render intelligible to the general reader the nature of what he has done for even *one* of these subjects, would require more space than is allowed us. His *Report on Double Refraction* was published in the British Association Reports for 1862. In 1869 he was president of the British Scientific Association.

STOLBERG, Christian, Count von, a German poet, born at Hamburg, October 15, 1748. He belonged to one of the oldest German families, originally of Thuringia, and which is mentioned in authentic documents of the 11th century. S. studied at Göttingen from 1769 to 1774, where he was one of a distinguished literary circle in North Germany, embracing Boje, Bürger, Miller, Voss, Hölty, and Leisewitz. In 1777, he married Luise, Countess of Reventlow, whom he had previously celebrated in his verses; and after 1800, lived apart from public life on his estate of Windebye, near Eckernförde in Slesvig, where he died January 18, 1821. As a poet, he was inferior in genius to his younger brother, but his pictures of family life are very fine. His principal works are *Gedichte* (Leip. 1779); *Gedichte aus dem Griechischen* (Hamb. 1782); *Schauspiele mit Chören* (Leip. 1787); and *Vaterländischen Gedichte* (along with his brother; Hamb. 1815).

STOLBERG, Friedrich-Leopold, Count von.

younger brother of the preceding, was born at Bramstedt, November 7, 1750, studied at Halle and Göttingen, and after a visit to Switzerland and Italy, in the course of which he made the acquaintance of Goethe at Frankfurt, and of Lavater at Zürich, he became, in 1777, minister-plenipotentiary of the episcopal Prince of Lübeck at the court of Denmark. S. filled various other official situations in the course of his public life; but becoming a convert to Roman Catholicism, he resigned all his employments, and henceforth lived mainly in the society of his co-religionists. The causes that led him to take a step which lost him many old and dear friends, were partly the theological strifes between the Rationalists and orthodox Lutherans in Holstein—the country where he mostly resided, and partly his study of the controversial works of the Catholic writers during a second visit to Italy in 1790—1791. He died at Sondermühlen, near Osnabrück, December 5, 1819. S. is a superior poet to his elder brother. There is greater boldness in his ideas and imagery, and he displayed a wonderful facility in versification. We have from him specimens of all sorts of poetry, songs, odes, elegies, metrical romances, satires, descriptive verse, and dramas, which are contained in the *Werke der Brüder Stolberg* (22 vols., Hamb. 1821—1826). See *Friedr.-Leopold, Graf zu Stolberg*, by Nicolovius (Mainz, 1846). A very good account of S.'s change of faith, and of that literary circle of North Germany in which he moved until his conversion, will be found in a book called *Entiner Skizzen* (Sketches of Entin), by Wilhelm von Bippen (Weimar, 1862).

STOLE (Gr. *stolē*, Lat. *stōla*, a robe) is the name of one of the sacred vestments used in the Latin Church, and with some modification, in the Greek Church also. It originated in a wide and flowing robe of linen, called also *orarium*, which hung from the shoulder, and which had a narrow embroidered border of a different colour, as we learn from St Ambrose's sermon on the death of Satyrus (n. 43), and from Jerome's letter to Nepotianus (Ep. 52). The present stole seems to be the traditionary representative of the embroidered border of the orarium in the Roman Catholic Church, and consists of a narrow band of silk or precious stuff, edged and fringed with gold or embroidery. It is worn over the shoulders by priests and deacons, but in a different fashion—the former wearing it over both shoulders, with the ends hanging in front, or crossed upon the breast; the latter carrying it only from the left shoulder to the right side, where the pendent ends are fastened. In the Eastern Church the stole is worn pendent, over both shoulders by priests, over the left shoulder only by deacons. The stole is worn at mass, and in the administration of sacraments, in certain blessings, and in more solemn forms of preaching. It is also used, in some cases, as a symbol of jurisdiction, in which sense it is constantly worn by the pope, even when not officiating; and there is a very remarkable usage in Italy and other Catholic countries, illustrative of the same principle as to jurisdiction, of the parish priest, after he has administered extreme unction to a sick person, *leaving the stole upon the foot of the bed, not to be withdrawn until the death or recovery of the invalid.* Like the other sacerdotal vestments, the stole must be blessed by a bishop, or a priest delegated by a bishop. In the English Church the stole is now generally used by the clergy, and is worn with the same difference by priests and deacons. In the case of dignitaries, doctors, and chaplains of noblemen or bishops, it is worn in the form of a scarf. The use of the stole in the English Church appears to rest only upon ancient custom, as it is not specified in any rubric or canon. It is usually of black silk, fringed at the ends, with sometimes crosses embroidered.

STOLEN GOODS, in point of Law, stand in this situation in England: a *bonâ fide* purchaser of such goods, who has not bought them in market overt, is bound to restore them to the true owner; but if the goods are sold in market overt, the purchaser is entitled to keep them, unless the owner has duly prosecuted and convicted the thief. Market overt means the open market in towns and places where a legal market is held, and the old doctrine was, that as all sales were conducted by exposure of goods in an open place, the owner of the lost goods was likely to find them easily by going to the nearest market—a doctrine which is now quite inapplicable to modern habits. In the City of London, every shop is held to be a market overt within the above rule, but this only applies to the City proper, and not the suburbs and western parts of the metropolis. The above rule, as to stolen goods, does not apply to valuable securities which are stolen, if the security has been paid or discharged *bonâ fide* by the person liable, or if the security is a negotiable instrument, and it have been *bonâ fide* transferred or delivered for a just and valuable consideration, without any notice, and without any reasonable cause to suspect that the same had been obtained by felony or misdemeanour. The law is obviously harsh as regards owners, for a man who has had the misfortune to have his goods stolen, must go to the further loss and expense of prosecuting the thief before he can recover them.—In the law of Scotland, it is otherwise. The owner has not only an action against the thief, but against third parties, whether they have bought them or taken them in pledge *bonâ fide* or not. But as to bank-notes, and bills payable to bearer, or blank indorsed, the property in these passes with the possession, and the real owner cannot vindicate them against one who has *bonâ fide* acquired them in the course of trade. As to giving reward for recovery of stolen goods, see REWARD, also RESTITUTION.

STO'LPE, a garrisoned town of Prussia, province of Pommern, and government of Cöslin, is situated on the river Stolpe, about 15 miles from its mouth, and 40 north-east of Cöslin. S., which is composed of an old and new town, with four suburbs, has a castle, 4 churches (one of which, the *Marienkirche*, built in 1311, has a tower nearly 190 feet high), a hospital for invalids, amber and other manufactures, and an active general trade. Pop. (1880) 21,599.—At the mouth of the river lies Stolpmünde (pop. 1118), the port of S., which carries on some ship-building and commerce.

STOMACH. The Anatomy and Physiology of this organ are treated of in the article DIGESTION (q. v.).

STOMACH, DISEASES OF. In the discussion of the diseases of any organ, it is customary to begin with the consideration of its inflammation. In the stomach, however, acute *gastritis*, or inflammation of the mucous membrane of that organ, is so rare a disease, except as a result of the administration of an irritant poison, that it might almost pass unnoticed. Thus Louis states that during six years' experience at La Charité (one of the leading Parisian hospitals), in which he made notes of 6000 cases of disease, and 500 dissections, he did not meet with a single case of fatal idiopathic (or spontaneous) gastritis. The simple fact, however, that this disease is almost always the result of poison, gives it a special interest, and renders it especially necessary that the physician should be so thoroughly acquainted with its symptoms, as to be able with

certainty to detect it, and thus to be led to investigate its cause.

The symptoms which indicate that an irritant poison has been received into the stomach, are a gradually increasing sensation of uneasiness or heat, which shortly assumes an acute burning character in the epigastric region. This pain is accompanied with vomiting, which becomes increasingly frequent as the pain augments, and often with hiccup. There is usually extreme tenderness on pressure, and the patient bends his body forward to relax the muscular tension. During the accession of these symptoms, there is a marked degree of excitement, as indicated by the acceleration of the pulse and breathing, and the heat of the skin. This condition is, however, soon exchanged for one of prostration. The skin becomes cold and clammy, the pulse thready and feeble, and the breathing catching and intermittent; until finally, after a variable period of exhaustion, the patient sinks, usually retaining his mental faculties to the last. Although the above-described symptoms are always more or less present, each irritant poison occasions some special symptom, and some characteristic lesion; and the period at which death ensues varies for different poisons. Hence, quite apart from the results of analysis, a fair conjecture can usually be made as to the individual poison which has been administered.

Sub-acute gastritis is by no means a rare affection, and it occurs in two distinct forms—'one in which the malady is caused by a constitutional state, the effects of which are shewn in a variety of other organs, as well as in the stomach; another in which it is due to causes connected chiefly or exclusively with this organ, which is submitted to an irritative process somewhat analogous to that typified by the gastritis of irritant poisoning.'—Brinton, *On Diseases of the Stomach*, 1859, p. 101. The first of these forms is well illustrated in certain cases of scarlatina, in which, if death takes place between the third and seventh day of the disease, distinct marks of inflammation are seen in the stomach. The other variety, which is often of a chronic form, is best seen in cases of delirium tremens; the affection being sub-acute or chronic, according as it has been produced by a single prolonged debauch, or by a protracted habit of drinking spirits; the patient's final malady being induced by a deficiency of food, or the want of the ordinary stimulant. Purely chronic inflammation may be induced by various causes, of which the most common are the abuse of alcoholic drinks, habitual excess in eating, the eating of indigestible food, and the excessive use of irritating medicines.

The treatment of gastritis varies so much with each individual case, that we shall only lay down a few general principles. The first point is the removal of the cause; to be attempted in cases of irritant poisoning, either by the removal of the poison (by the stomach-pump or emetics, as, for example, sulphate of zinc), or by its neutralisation by means of an antidote. In very severe cases, leeches may be applied to the epigastrium; but counter-irritants, such as turpentine on a hot moist flannel, or mustard-poultices, are generally of more service. Continuous fomentation with water, as hot as can be borne, often gives great relief; while at the same time iced water, or small lumps of ice swallowed whole, usually relieve the thirst and mitigate the pain. Enemata of purgative materials, if the bowels are constipated, or of a soothing character (as thirty drops of laudanum in a little starch or gruel), if the bowels are irritable, may be prescribed with advantage. When the stomach begins to be able to retain food it must be given in the form of a bland liquid, in small doses, at distant intervals. Chronic gastritis must be treated in much the same manner as Indigestion (q. v.). The most essential point of treatment is the due regulation of the diet.

Ulcer of the stomach is the most important of the idiopathic diseases of that organ, both from its frequency, from the facility with which it may be detected during life, from the fact that at any period of its protracted course it may prove suddenly fatal, and from its being usually curable. The first and most characteristic symptom of this disease is pain, which commences as a mere dull feeling of weight or tightness, then gradually augments into a burning sensation, and at last assumes a gnawing character, and occasions a kind of sickening depression. This pain comes on in from two to ten minutes after the ingestion of food, and lasts for an hour or two; vomiting often ensues, after which the pain ceases. The place of its most common appearance and greatest intensity is the centre of the epigastric region, or slightly below the free end of the ensiform cartilage of the sternum; and the painful spot is usually of a circular form, with a diameter varying from one to two inches. The pain in this region is succeeded, in the course of a few weeks, by a gnawing pain in the back, ranging in position from the eighth dorsal to the second lumbar vertebra, and most commonly lying between the two shoulder-blades. The pain in both the epigastric and the dorsal region is almost always much increased by pressure; it is also specially affected by certain kinds of food and drink, being increased by the ingestion of hard and indigestible substances, and lessened by a bland and pulpy diet. As a general rule, the pain is aggravated by tea, beer, and hot food; although exceptions occasionally occur. The next symptom in this disease is vomiting or regurgitation, expelling the food previously taken, or a glairy alkaline fluid. The vomiting usually occurs when the pain is most intense, and is a dangerous symptom, since it tends to starve the patient, and to increase the fatigue of an already weakened frame. At this stage, the disease is sometimes terminated by the occurrence of perforation, ending in rapidly fatal peritonitis; and if this accident does not occur, the dyspeptic symptoms become complicated by hæmorrhage from the stomach, sometimes so rapid that it distends the stomach and adjacent small intestine with a single gush, and causes fainting and almost immediate death; but more commonly occurring as a slow and intermittent drain of blood, giving rise to anæmia. If death from the above causes (inanition, perforation, or hæmorrhage) does not terminate the disease, the symptoms frequently subside in something like the inverse order in which they occurred, and recovery, often after many years' suffering, ensues. With regard to frequency of ulcer of the stomach, Dr Brinton, who has carefully studied this disease, states that this lesion may be detected in (on an average) 5 per cent. of persons dying from all causes; that it occurs twice as frequently in females as in males, and that it is specially a disease of middle and advancing life—27 being the average age in females, and 42 in males. Nothing is known with certainty regarding the causes of this disease, except that advancing age, privation, mental anxiety, and intemperance so frequently coincide with it, that they may be regarded in some degree as producing it. In relation to treatment, strict attention to diet is of the first importance. When the symptoms are urgent, the patient should maintain the recumbent position, and should be fed on lukewarm milk, thickened with biscuit-powder, given in doses of

one, or, at most, two table-spoonfuls every two hours. The pain is often relieved by the application of a mustard-poultice to the painful spot; and benefit is frequently derived from the internal administration of bismuth (in doses of ten grains), either given alone or combined with the compound kino powder (in five-grain doses). When there is hæmorrhage, small lumps of ice may be swallowed; and if all food is rejected by vomiting, beef-tea injections must be thrown into the lower bowel. Aperients are sometimes required, but they must be given with caution; and if castor-oil can be taken without increasing the pain or vomiting, it is the most harmless remedy of its class.

Cancer of the stomach is a disease of much interest, from its being obscure in its symptoms and difficult of detection in its early stage, frequent in its occurrence, and always fatal in its termination. The typical course of this disease is graphically sketched by Dr Brinton in the following paragraph: 'An elderly person perhaps hitherto free from dyspepsia, begins to suffer from a capricious, and soon a diminished appetite; which is by and by associated with occasional nausea, or even vomiting, and with a sense of uneasiness or distention of the stomach. His complexion, already pale and unwholesome, next acquires a muddy, yellowish, or faint greenish hue. His gastric symptoms now increase; often by a sudden and marked augmentation, which corresponds to what is in other cases their first appearance. Vomiting, if already present, becomes more frequent and urgent; local uneasiness deepens into pain; and both these symptoms are excited or increased by taking food. At a somewhat later period, hæmorrhage generally occurs, usually but scanty in amount, and therefore depending to a great extent on casual circumstances for its detection. About this time, a tumour often becomes perceptible near the middle of the epigastric region of the belly. As the local symptoms increase, the cachexia of the patient also augments; and is evidenced not only by the colour already mentioned, but also by debility and emaciation; and at last by prostration, which ends in anasarca, delirium, and death.'—*Op. cit.*, p. 225. From the records of 600 cases, Dr Brinton finds that most deaths from this disease occur between the ages of 50 and 60 years. The form of cancer which most frequently attacks the stomach is the scirrhus or hard cancer. Out of 180 cases, scirrhus occurred in 130 (or nearly three-fourths of the whole), medullary or encephaloid cancer in 32, colloid in 17, melanotic deposit in 3, and villous cancer in 1. In the treatment of this formidable disease, more good is done by careful attention to the diet than by any medicine. Good milk or strong beef-tea thickened with biscuit-powder, may be given in the same manner as recommended in ulcer; and milk mixed with a little old Jamaica rum will sometimes stay on the stomach when everything else is vomited. If there be pain, opiates must be given, and they may be prescribed either in the ordinary way, or as enemata, the latter having the advantage of not inducing constipation.

Hæmatemesis, or *Vomiting of Blood*, must be looked upon rather as a symptom than a disease. Thus, it may occur by the ulcerative destruction of the walls of a comparatively large blood-vessel, as in gastric ulcer and in cancer; but it generally is of the kind termed capillary. The latter kind of hæmorrhage happens under various circumstances, of which the following are the principal: 1. The bleeding may be idiopathic, or unaccompanied by any structural change. This variety is extremely rare. 2. It may take the place of some habitual hæmorrhage, or, in other words, be vicarious. Thus it frequently takes the place of the menstrual discharge. 3. It is often a consequence of disease or injury of the stomach; for example, it frequently occurs after the ingestion of strongly irritant poisons, or even an immoderate dose of alcohol into the stomach. 4. It may be a consequence of disease in adjacent viscera, occasioning an overloading of the veins of the stomach; thus it is frequently caused by enlargement of the spleen, and occurs in those states of the liver in which there is obstruction of the portal circulation; and under this category we must place the gastric hæmorrhage which not unfrequently occurs in the advanced periods of pregnancy, in consequence of the pressure exerted by the enlarged uterus on the venous circulation of the abdomen. 5. It may result from changes in the composition of the blood, such as occur in scurvy, purpura, and yellow fever. The treatment must be directed against the disease on which the hæmorrhage depends, rather than against the mere symptom; but from whatever cause it arises, if it is proceeding to a dangerous extent, the patient should be kept perfectly quiet in bed, and should swallow small pieces of ice. Hot applications may also be applied to the extremities, with the view of directing the blood to those parts. The medicines most likely to be of service are acetate of lead, gallic acid, dilute sulphuric acid, and oil of turpentine; but they should only be given on medical authority.

Some of the other affections of the stomach are discussed in special articles. See CARDIALGIA, INDIGESTION, SARCINA, &c.

STOMA'PODA (Gr. mouth-footed), an order of malacostracous crustaceans, to which *Squillidæ*, Glass-crabs, &c. belong. All of them are marine. They are most abundant in tropical seas, but some are found in those of temperate parts of the world. They have seven or eight pair of legs, mostly near the mouth. The gills are external, adhering to the appendages beneath the abdomen, which is elongated, and terminates in an extended tail-fin. The rings which bear the eyes and the antennæ are not confounded with the rest of the head, as in the *Decapoda*, but are more distinct. The carapace often leaves the latter rings of the thorax exposed. The heart is very different from that of the *Decapoda*, assuming the form of a long cylindrical vessel, which extends throughout the length of the abdomen.—The S. inhabit deep parts of the sea, many of them living at the bottom, whilst some, as Glass-crabs, are found floating at the surface.

STO'MATA (Gr. mouths) are minute openings in the epidermis of leaves and other green parts of plants exposed to the air, communicating with intercellular spaces. Their existence was first noticed by Grew, who described them in his *Anatomy of Plants* in 1682. They are generally formed by two semilunar cells, which are as lips to the orifice, and are filled with green matter; but sometimes the cells arranged around them are more numerous. They are generally of an elliptical form, but sometimes circular, and sometimes quadrangular. These differences are very characteristic of particular species, genera, or orders of plants. In a moist state of the atmosphere, they are open; but when it becomes dry, they are closed, or nearly so. It appears that they are organs of transpiration, and that their opening and closing according to the moisture or dryness of the atmosphere regulates it in a manner suitable to the requirements of the plant. They do not occur in any part of the plant covered by the soil, nor in submerged leaves, nor on the lower side of floating leaves. Succulent plants have very few of them; so that these plants retain for a long time the moisture which they have imbibed, and are thus adapted for living in a dry atmosphere. S. are generally

most abundant on the under side of leaves; but in leaves which grow vertically, they are often almost equally numerous on both sides. In general, they are irregularly placed; but in grasses and many other endogenous plants with parallel-veined leaves, they are in regular rows; and in some other plants they occur in little groups. The number in a square inch varies from 200 in the mistletoe, to almost 450,000 in the under side of the leaves of *Solanum sanctum*.—S. are not found in mosses, lichens, algæ, and fungi; but they exist in some of the *Hepaticæ*, as in *Marchantia*, in which their structure is more complex than in the higher plants; each of them consisting of a kind of shaft, composed of four or five rings placed one upon the other, every ring made up of four or five cells, and the lowest ring apparently regulating the aperture by the contraction or expansion of the cells which form it.

STONE, a market-town of Stafford, stands 7 miles north-north-west of the town of that name, on the left bank of the Trent. Shoemaking, tanning, malting, and brickmaking, are the chief branches of industry. Near the church are some remains of an Augustinian monastery. Pop. (1851) 3443; (1861) 4509; (1871) 3732; (1881) 5669.

STONE, a weight in use throughout the north-west and central countries of Europe, but varying much in different countries. It is chiefly employed on the continent for weighing wool, hemp, flax, and feathers, the flax-stone containing twice as many pounds as the one used for wool and feathers. In all the principal commercial states of Germany, the stone (of flax) is the $\frac{1}{5}$th of a cwt. (centner = 100 or 112 lbs.), i. e., 20 lbs., in Prussia and the Zollverein, Hamburg, Lübeck, and Bremen; 22 lbs. in Austria, &c.; in Britain, it is the $\frac{1}{8}$th of a cwt., or 14 lbs.; while in Sweden it is equivalent to 32 lbs. In Great Britain, though the stone of 14 lbs. is the only legal imperial weight of the kind, stones of other values are in regular use, as a stone of 24 lbs. for wool, and one of 8 lbs. for butcher-meat.

STONE. See CALCULUS and LITHOTOMY.

STONE is used for a great variety of purposes—for building, paving, millstones, grindstones, hone-stones, ornamental purposes, &c. Besides what is said under special headings (see BUILDING STONE, QUARRY, MILL, GRINDSTONES, HONES, MARBLE, GRANITE, SLATE, &c.), the following general remarks may be added here. The desirable properties in a building-stone are, that it should be compact, insoluble in water, not easily altered by the atmosphere, and not liable to take on a vegetable coating. These qualities depend upon its chemical composition and on its mechanical structure. Building stones may be divided into three classes—siliceous, calcareous, and composite. Siliceous stones (including granite, porphyry, gneiss, greenstone, basalt, sandstone, slate, serpentine, &c., and containing from 45 to 99 per cent. of silica) are, as a general rule, the most durable for building. Their durability is affected by certain of their ingredients, as by the felspar in granite, and salts of iron in sandstone. Calcareous stones (simple limestone, travertin, marble, &c.) are slightly soluble in pure water, and more so in carbonic acid water; they are liable to splinter by water freezing in their pores, are acted on by acid gases (e. g., the sulphurous acid gas produced by the combustion of most kinds of coal), and are somewhat liable to be stained by minute plants. Still, some of them are lasting enough in a country atmosphere. The failure of the magnesian limestone selected for the British Houses of Parliament is a good instance of a stone lasting for centuries in a country church, and yet quite unable to withstand the wasting action of the atmosphere of a great city. Composite stones, in which neither the silica nor the lime greatly predominates, are unimportant.

The most exhaustive account of the building stones of the British Islands is given in the parliamentary Blue Book embodying the Report of the Commissioners appointed to select a stone for the Houses of Parliament, published in 1839. Much scientific information regarding all kinds of stone will be found in the catalogue of the Rock Specimens of the Museum of Practical Geology, London.

STONE, ARTIFICIAL. Artificial stone, properly speaking, would include burned clay wares used for building purposes, as bricks, Terra Cotta (q. v.), &c., as well as the various cements. We shall confine ourselves here to a description of the siliceous artificial stone produced by the cementing properties of soluble alkaline silicates on sand, which has excited a great deal of attention within the last ten or twelve years. So far back as 1825, Professor J. N. von Fuchs of Munich published a paper on various applications of these silicates, and so laid the foundation of a new industry. To M. Kuhlmann of Lille, however, is mainly due the merit of working out the practical application of the soluble silicate of potash or soda to the manufacture of hydraulic lime, cement, and especially to artificial stones. Mr Frederick Ransome of Ipswich has also done great service by his successful exertions in producing an artificial stone from the same substances. The process, as at first practised by Mr Ransome, consisted in mixing the gelatinous silicate of soda with sand and a little powdered glass and clay, in the proportions of sand, 10 parts; glass, 1 part; clay, 1 part; and silicate of soda, 1 part. These ingredients were thoroughly incorporated in a pug-mill, and brought to the consistency of putty. The plastic nature of the substance at this stage allows it to be moulded with ease into an endless variety of forms, even of an elaborately ornamental kind. After leaving the moulds, the objects are dried in close ovens, and then removed to kilns, where they are fired at a gradually increasing temperature, which finally reaches a red heat. In the kiln, the goods are bedded up in dry sand, to prevent any of the twisting or loss of shape which so commonly disfigures large objects in baked clay. When the firing is completed, the material is in the state of a semi-vitrified mass, with the appearance, properties, and composition of a fine sandstone.

A more recent patent of Mr Ransome's consists in producing a hard and durable material altogether without baking, by effecting a double decomposition with the silicate of soda and the chloride of calcium. Such materials as sand, chalk, or other minerals are intimately mixed with a proper quantity of a solution of silicate of soda, this being secured, as before, by the operations of a pug-mill. In this plastic condition, they are moulded into any required form, after which they are saturated with a solution of chloride of calcium. The silica combining with the calcium forms at once an insoluble silicate of lime, which cements into a firm mass all the particles of sand, lime, &c. used in the composition. The chlorine, on the other hand, combines with the soda to form common salt (chloride of sodium), which can be readily removed by washing.

The great advantage of this 'Patent Concrete Stone,' as it is called, is, that it can be manufactured on the spot, wherever it is required. There is reason to believe that it will also be less affected by town atmospheres than many natural building-stones. In point of transverse strength, it is superior to Portland stone, bearing, in fact, twice as

much weight, in the form of a bar, before it breaks. It also considerably excels it in cohesive power.

The objects into which artificial stone is manufactured are very miscellaneous. Among the more prominent applications of it, we may notice grindstones, millstones, fountains, vases, statuary, &c. See *Rep. of American Commissioners to Paris Exhibition*, vol. iii., Washington, 1869; also *Practical Treatise on Soluble Glass, &c.*, by Dr. L. Feuchtwanger, 1870.

STONE-CHAT (*Saxicola rubicola;* see CHAT), one of the most common of the British *Sylviadæ*, a pretty little bird, rather smaller than the redbreast,

Stone-chat (*Saxicola rubicola*).

black on the upper parts and throat in summer; the breast of a dark reddish colour; some white on the sides of the neck, the wings, and the tail. It makes its nest on the ground, or on a low branch. Some stone-chats spend the winter in Britain, but the greater number migrate to more southern regions.

STONECROP. See SEDUM.

STONE-CUTTING AND DRESSING MACHINES. Stone is a substance which in none of its varieties is easily operated on by machinery, owing chiefly to its brittleness, its unequal hardness, and the natural cracks which so frequently impair its solidity. Accordingly, though many ingenious machines have been invented for working stone, it is as yet only in some of the plainer kinds of work that they can be said to have entirely superseded hand operations.

Some stones and slates are soft enough to be cut with ordinary toothed saws much in the same way

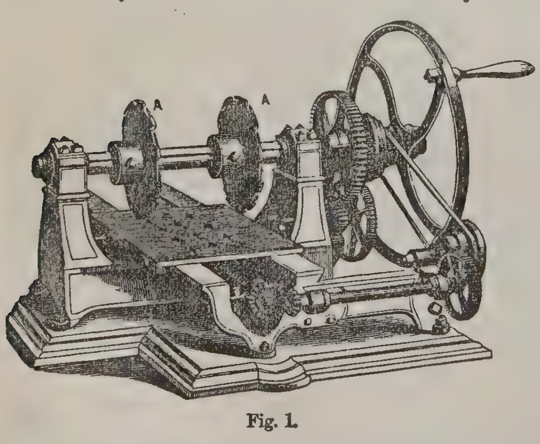


Fig. 1.

as wood is cut. More generally, however, the sand-saw is employed, which we shall presently describe in noticing marble-cutting. For the cutting of common kinds of stone, which are not to receive a fine polish, a machine, which promises to be very efficient, has been recently patented by Mr George Hunter of Maentwrog, Caernarvon, and is now in operation at various large quarries, both of stone and slate. The cutting portion consists (fig. 1) of a circular disc, A, A (two of these are shewn in the figure, but the number varies), round the circumference of which a number of pointed steel tools are fixed into sockets, thus giving it the appearance of a large toothed saw. The following is stated to be the rate per minute at which this machine will cut various well-known stones, supposing them to be in blocks each 2 feet thick: slate, 3 inches; Portland stone, 5 to 6 inches; sandstone, 5 to 6 inches; soft limestone, 3 inches; Arbroath flagstone, 5 to 6 inches; and Caithness flagstone, 5 inches.

It is now more than a century since machinery for sawing and polishing marble was first established at Ashford, near Bakewell, in Derbyshire, that county being still the seat of the principal marble manufacture of England. Marble is cut into slabs by means of a series of thin plates of soft iron used like saws, but having no teeth. The saw-blades are fixed into a rectangular frame, to which a reciprocating horizontal motion is given. The block of marble to be cut rests on a carriage below the frame, and a small rill of mixed sand and water is constantly falling into each of the saw-cuts.

A stone-cutting machine, said to be distinguished by the simplicity and rapidity of its action, was invented a few years ago by a Frenchman, in which the operation of sawing is effected by a thin iron wire running over the stone at the rate of 40 feet per second, but we are not aware how far it has been actually used.

After the marble has been sawn into slabs, it is cut up into narrow pieces, when so required, by means of small circular saws with smooth edges, sand and water being employed as above.

The sawn slabs are next submitted to the grinding process. This, for pieces of moderate size, is usually done upon a large circular cast-iron plate, called a *sanding-bed* or *grinding-bed*, mounted upon an upright spindle, and supplied with sand and water. The workman places the piece of marble with its face downwards upon the grinding-bed, and exerts the proper amount of pressure. The marble is held in its place by means of guide-rods stretched across the plate. Slabs too large to be manipulated in this way are ground with plates of iron operating upon their surface.

The marble, when properly ground, is polished on a polishing bed or table, with an arrangement for securely fixing it while the rubbing is being proceeded with. The polishing rubbers are sometimes blocks of wood faced with felt, and sometimes bunches of hemp compressed between two side-plates. They are attached to a swing-frame with a pendulum-like motion, which draws them backwards and forwards over the surface of the marble. Flour emery is used to charge the rubbers in the first instance, and putty-powder (oxide of tin) for the finishing polish. Instead of emery, sometimes the fine-grained stone known as Water of Ayr stone is used to prepare the marble for the putty-powder.

Cylindrical objects, such as columns or vases, are first formed roughly into shape with a hammer and chisel, and then turned, with a pointed steel tool, upon a lathe, to which a slow motion is given. When thus brought to an accurate form, a rapid motion is given to the lathe and the tool-marks ground away by the use

of coarse, and then fine, and still finer sandstones—the polishing being completed with emery and putty powder while the object is still upon the lathe.

Machinery is also applied to the production of flat objects with curved and moulded outlines. Fig. 2 represents the essential parts of a machine for this purpose. It operates by the use of a rotatory cutter, which is guided in its action by a template formed accurately to the intended shape of the article.

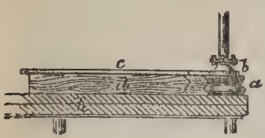

Fig. 2.

The cutter, *a*, is of steel or stone, and is attached to the lower end of a spindle driven by bevelled wheels. There is a flange at *b*, which allows the cutter to penetrate the marble till it reaches the template, *c*, and no further. In the process of cutting, the marble, which we will suppose is to receive the shape shewn at S (fig. 3), but only seen on edge at *d*, in fig. 2, is constantly drawn up against the cutting-tool by two weights, the one pulling the table, *h*, in one direction, the other the carriage on which *h* rests, in a direction at right angles to the former, thus compelling the cutter to follow the outline of the template. The shape of the cutting-tool is, of course, exactly the reverse of the moulding to be formed.

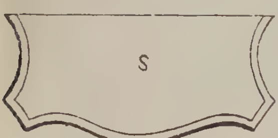

Fig. 3.

In the cutting and polishing of granite, the machinery and processes are so nearly the same as those employed for marble, that it is unnecessary to describe them separately. Suffice it to say, that all objects to which the sawing apparatus cannot be applied, require to be worked to shape with great care by means of steel chisels and iron mallets, which only remove small portions at a time. Owing to the great hardness of the material, any defect in the chiselling greatly increases the labour of polishing. The slow operations of stone-cutting and polishing can now be greatly expedited by the application of the 'sand blast' of Tilghman, introduced in Philadelphia in 1871. See SAND BLAST.

STONE-FLY (*Perla*), a genus of Neuropterous insects, of the tribe or family *Planipennes*. The hind wings are broader than the fore-wings, and folded at the inner edge. The body is elongate, narrow, and flattened; the wings close horizontally on the body; the abdomen is generally terminated by two bristles (*setæ*). The larvæ are aquatic, and much resemble the perfect insect, except in the want of wings. A number of species are common in Britain, and are well known to anglers as an attractive lure for fishes.

STONE-FRUITS, in Popular Language, are those fruits which are botanically designated *drupes*, and in which the rind is fleshy, and the putamen bony. Many of the finest dessert fruits are of this description. Those best known in temperate climates generally belong to the natural order *Rosaceæ*, sub-order *Amygdaleæ*, the order *Drupaceæ* of Lindley, as the peach and nectarine, plum, cherry, apricot, &c. In tropical countries, many stone-fruits occur, belonging to *Chrysobalanaceæ* and other natural orders.

STONEHA'VEN, a seaport town of Scotland, capital of the county of Kincardine, and a station on the railway from Dundee to Aberdeen, is situated on a rocky bay at the mouth of Carron Water. It is divided into an Old and New Town, on different sides of the river, and connected by a bridge. The harbour can admit only small vessels. S. has very considerable haddock and herring fisheries, and some slight manufactures. Pop. 3009. Two miles south, on a projecting rock, stands the famous castle of Dunnottar, once the residence of the Earls Marischal.

STO'NEHENGE (Sax. *Stanhengist*, hanging or uplifted stones), a very remarkable structure, composed of large artificially raised monoliths, situated on Salisbury Plain, two miles from the town of Amesbury, in Wiltshire. Its neighbourhood abounds in sepulchral tumuli, in many of which ancient British remains have been found. The fabric of S., which was comparatively entire in the early part of the present century, has been so much defaced in recent times as to be at first view little more than a confused pile of moss-grown stones; but a minute inspection will still enable one to trace its original form. When entire, it consisted of two concentric circles of upright stones, enclosing two ellipses, the whole surrounded by a double mound and ditch circular in form. Outside the boundary was a single upright stone, and the approach was by an avenue from the north-east, bounded on each side by a mound or ditch. The outer circle consisted of 30 blocks of sandstone, fixed upright at intervals of 3½ feet, and connected at the top by a continuous series of imposts, 16 feet from the ground. The blocks were all squared

Stonehenge.

and rough-hewn, and the horizontal imposts dovetailed to each other, and fitted by mortise-holes in their under sides to knobs in the uprights. About 9 feet within this peristyle was the inner circle, composed of 30 unhewn granite pillars, from 5 to 6 feet in height. The grandest part of S. was the ellipse inside the circle, formed of 10 or 12 blocks of sandstone, from 16 to 22 feet in height, arranged in pairs, each pair separate, and furnished with an impost, so as to form 5 or 6 trilithons. Within these trilithons was the inner ellipse, composed of 19 uprights of granite similar in size to those of the inner circle; and in the cell thus formed was the so-called altar, a large slab of blue marble.

There has been much speculation regarding the origin and purpose of S., which are still involved in much obscurity. A curious legend, first found in the *British Chronicle* of the 10th c., and repeated by Geoffrey of Monmouth and Giraldus Cambrensis, ascribes it to Emrys or Ambrosius, the last British king, who, in the 5th c., aided by the incantations of the magician Merlin, is said to have erected it in memory of 460 Britons, who were murdered by Hengist the Saxon. In modern times, the most prevalent opinion has been that, in common with other similar structures elsewhere, it was a

temple for Druidical worship; but this belief has been somewhat shaken by the discovery of the sepulchral character of many other monuments, which have been also presumed to be Druidical. The circular form has suggested the idea of a connection with the worship of the sun; and S. may possibly have been used for the religious rites of various successive races and creeds; and also as a court of justice or battle-ring for judicial combats. The outer circle is evidently of a much later date than the rest, and seems to belong to a period when iron tools were in use. See STANDING STONES.

STO'NEHOUSE, EAST, a parish of Devonshire, included within the limits of the parliamentary borough of Devonport (q. v.), and forming in effect a portion of Plymouth (q. v.). Among other government establishments, it contains the Royal William Victualling Yard, naval hospital, and marine barracks capable of accommodating 1000 men. Pop. of parish (1851) 11,979; (1861) 14,343; (1881) 15,125.

STONE PERIOD. See BRONZE, AGE OF.

STONE-POCK, an old name for a variety of modified smallpox, in which the vesicles dried up into hard tubercles instead of proceeding onwards to maturation.

STONE, PRESERVATION OF. The mechanical preservation of stone can be effected to a great extent by coating the surface with boiled linseed oil, or with oil-paint; but these methods are not much in favour, as they destroy the crystalline appearance which constitutes the beauty of most natural stones. As promising a better result, many experiments have been tried, especially of late, with certain chemical solutions that are not likely to mar the inherent beauty of a stone. The substances which have been most used are those soluble silicates which we have referred to under ARTIFICIAL STONE. The earlier process of Kuhlmann consisted in coating the surface with a soluble silicate of soda or potash, which is also known by the names of soluble glass, water-glass, and flint liquor. This was applied with a brush, and silification was produced by the silica of the solution entering into combination with the lime of the stone; but this took a considerable time, so that, on an exposed front, it was liable to be washed out before the proper hardening took place. The later process of Ransome consists in cleaning the surface of the stone from extraneous matter, and then applying alternate solutions of the above alkaline silicate and chloride of calcium, which forms an insoluble silicate of lime in the pores of the stone. This plan has been tried with a portion of the new Houses of Parliament, and has been frequently reported as successful. But as the question of preserving this very building has been the subject of public inquiry since the above was tried, namely, in 1861, and the labours of the committee who sat, aided by a chemical sub-committee, did not succeed in discovering any preserving agent which they felt justified in proposing, the efficacy of Ransome's process cannot be held as settled. The chemists engaged in this inquiry select, from a vast number of proposals then made, the following processes, as claiming a careful investigation: 1. Application of silicates of the alkalies, in various states of concentration; 2. Application of silicates, in conjunction with various saline compounds, intended to produce double decomposition; 3. Application of hydrofluoric or hydrosilicic acid, or their saline compounds; 4. Application of phosphoric acid and acid phosphates; 5. Applications of solutions of the alkaline earths, or their bicarbonates, in water.

STONE-WARE. See POTTERY.

STO'NINGTON, a town and port of entry of Connecticut, U. S., at the eastern extremity of Long Island Sound, 63 miles east of New Haven, and at the junction of one of the railway and steamer routes between New York and Boston. It has a fine harbour, with 13,000 tons of shipping, engaged in coasting-trade and fisheries, and numerous manufactories. S. was settled in 1649. Pop. (1880) 7353.

STO'NY POINT, a small rocky promontory on the right bank of the Hudson River, at the entrance of the Highlands, 42 miles north of the city of New York. This and the opposite Verplancks Point were fortified in the war of the Revolution, and were the scene of several contests.

STOOL OF REPENTANCE, the name ordinarily given in Scotland to a low stool conspicuously placed in front of the pulpit in churches, on which persons who had become subject to ecclesiastical discipline for immoral conduct were required to sit during public worship, in profession of their penitence, or on which they stood at the close of the service to be 'rebuked' by the minister. It was also familiarly called the *cutty* stool, a term applied to small stools of similar form, common in houses, but which came to be often employed in conversation and in humorous verses with special reference to that which stood in the church. Transgressions of the seventh commandment being far more frequently the cause of occupying the Stool of Repentance than offences of any other kind, the jokes which abounded on the subject of this piece of church-furniture were neither indicative of a pure morality nor calculated to promote it; and the Stool of Repentance, although used in some places within the present century, has now fallen into complete disuse; whilst the practice of formal public rebuke, as a part of Church-discipline (q. v.), has also generally been laid aside.

STOP, or **REGISTER**, a name given to the different ranges of pipes in an organ. Each stop consists of a series of pipes, of the same quality of tone, extending throughout the whole or a large part of the compass of the instrument, and furnished by a draw-stop or knob, on drawing which out, the air is admitted to the particular stop, so that the keys will play on pipes of that character. Some of the stops do not give the note which corresponds in pitch with the key struck, but a note an octave or two octaves lower, or one of the harmonics higher in pitch. Compound or mixture stops consist of more than one row of pipes to each key, corresponding to the different harmonics of the ground tone. The stops of different organs vary much in number and kind; a very large number are to be found in many of the organs in Germany and Italy. See ORGAN.

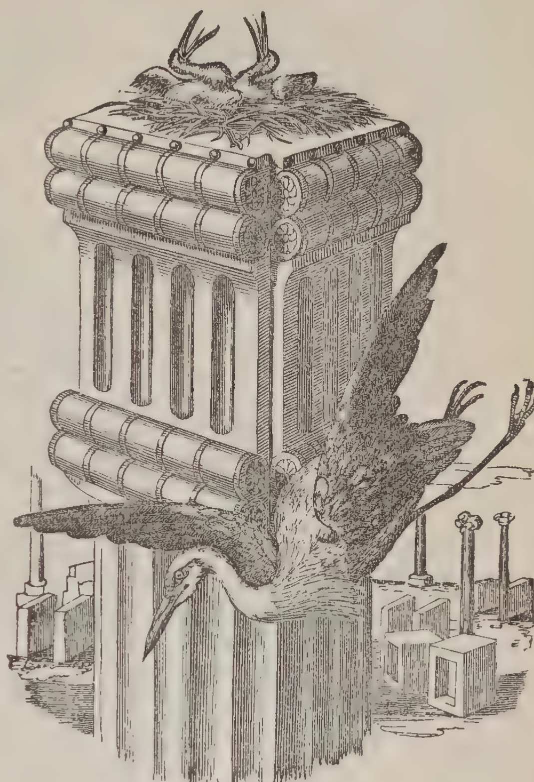
STO'PPAGE IN TRA'NSITU is a valuable right or privilege of a vendor of goods to resume possession, after he has parted with them under a contract of sale, and before the goods have reached the vendee. It occurs when goods are consigned entirely or partly on credit from one person to another, and the consignee becomes bankrupt before the goods arrive. In this event, the consigner has a right to direct the captain of the ship or other carrier to deliver the goods to himself or his agent instead of the consignee, who has thus become unable to pay for them. This right was first allowed as equitable by the Court of Chancery, and the courts of common law followed the example. There are certain circumstances, however, in which the right to stop *in transitû* may be defeated, as where the consignee of the goods indorses the bill of lading to a *bonâ fide* indorsee. When the vendee has appointed the carrier who is to receive the goods, their delivery to the carrier is treated for many purposes as

delivery to the vendee himself; yet it is not too late for the vendor to stop the goods so long as they have not come into the actual possession of the vendee. The right to stop *in transitû* is not allowed to a vendor unless in case of the bankruptcy of the vendee or his stoppage of payment.—The same rule extends to Scotland.

STOPPAGES, Military and Naval, are certain deductions made from the pay of officers and men, in consideration of supplies made to them, or in aid of certain institutions. These stoppages were formerly more numerous than now. Thus, every officer and man had to pay towards Chelsea and Greenwich hospitals, and a soldier had to pay for his kit by a stoppage from the bounty. These stoppages have been remitted. Those now remaining are, under ordinary circumstances, limited in the navy to payment for slops (i. e., clothing) issued to men, or for wilful damage: in the army, to payment for the daily Ration (q. v.); for forage, 8½*d.* each ration by cavalry officers, and 6*d.* for artillery officers (though their horses eat the same); for messing on board ship; for diet in hospital; for cost while in prison; for washing sheets; and for damages to barracks.

STO'RAX, a fragrant resinous substance, the *Styrax* of the ancients, obtained from the Storax-tree (*Styrax officinalis*), a native of the countries around the Mediterranean Sea, and belonging to the natural order *Styracaceæ*, an order of exogenous plants, containing more than 100 known species. The species of this order are found in the tropical and subtropical parts of Asia, extending also into Europe and Africa, and the warm parts of America. *Styrax officinalis*, which produces S., is a tree of 15—20 feet high, a native of the Levant. S. is obtained by wounding the bark, when it exudes and hardens in the air. It appears in the form of reddish-yellow tears about the size of a pea, opaque, soft, and adhesive; or in dry brittle masses, wrapped in the leaves of a kind of reed, when it is called *S. calamita*. S. has a fragrant odour and an aromatic taste, and is stimulating and expectorant. It was formerly much more in use in medicine than now. Benzoin (q. v.) is the produce of a species of *Styrax*. The *Liquid S.* of the shops is doubtfully regarded either as produced by *Styrax officinale*, or by a species of *Liquidambar* (q. v.). It seems probable that there are two kinds.

STÓRK (*Ciconia*), a genus of birds of the same family (*Ardeidæ*) with herons and bitterns; large birds; with long legs, four-toed, the three front toes webbed to the first joint; the tail short; the wings large; the bill longer than the head, straight, strong, pointed, and without any groove, the nostrils pierced longitudinally in the horny substance; the eyes surrounded by naked skin. The species are not numerous, but they are of very wide geographic distribution. The Common S., or White S. (*C. alba*), is a native of the greater part of the Old World, a migratory bird, its range extending even to the northern parts of Scandinavia. It is common in most parts of Europe. It is about three feet and a half in length. The head, neck, and whole body are pure white; the wings partly black; the bill and legs red. The neck is long, and generally carried in an arched form; the feathers of the breast are long and pendulous, and the bird often has its bill half hidden among them. The S. frequents marshy places, feeding on eels and other fishes, batrachians, reptiles, young birds, and small mammals. It makes a rude nest of sticks, reeds, &c., on the tops of tall trees, or of ruins, spires, or houses. In many parts



Stork's Nest at Persepolis.

of Europe, especially in Holland, it is a very common practice to place boxes for storks, and it is considered a fortunate thing for a household that the box on the roof is occupied. Storks are protected by law in some countries, on account of their good services not only in destroying reptiles and other troublesome animals, but in the removal of offal from the streets of towns, in which they stalk about with perfect confidence, even in the midst of throngs of people. They have been celebrated from ancient times for the affection which they display towards their young; and have also had the reputation—not so well founded—of shewing great regard to their aged parents. Before they take their departure from their summer haunts, they congregate in large flocks, which make a great noise by the clattering of their mandibles, and are popularly regarded as holding consultation. The S. has no voice. Its flight is powerful, and very high in the air. It is a very rare bird in Britain, and was so even when the fens of England were undrained. The flesh of the S. is rank, and not fit for food.—Another species, the Black S. (*C. nigra*), rather smaller, the plumage of the upper parts glossy black, the under parts white, is also common in many parts of Europe, Asia, and Africa.—The American S. (*C. maquari*) is very similar to the Common Stork.

STORMS are violent commotions of the atmosphere, occurring in all climates, particularly

the tropics, and differing from other atmospheric disturbances in the extent over which they spread themselves, their destructive power, and the sudden changes which take place in the direction of the wind. There is, perhaps, no question in science in which there has been so large an admixture of speculation with fact, as in the attempts made to reduce the phenomena attendant on storms under general laws; the reason being, that meteorological observatories were too few in number, and too wide apart, to enable any one to give the barometer pressure, the general course of the winds, and the rainfall, without drawing largely on conjecture. Now, however, owing to the growing popularity of meteorology, and the countenance happily given to it by most civilised nations, sufficient data have been obtained for a fuller and more satisfactory statement of the facts.

We subjoin two charts of Europe, shewing, from actual observations made at upwards of 100 localities scattered over that continent, the barometric pressure, and direction and force of the wind, at 8 A. M. of the 1st and 2d of November 1863, during part of the course of two storms which

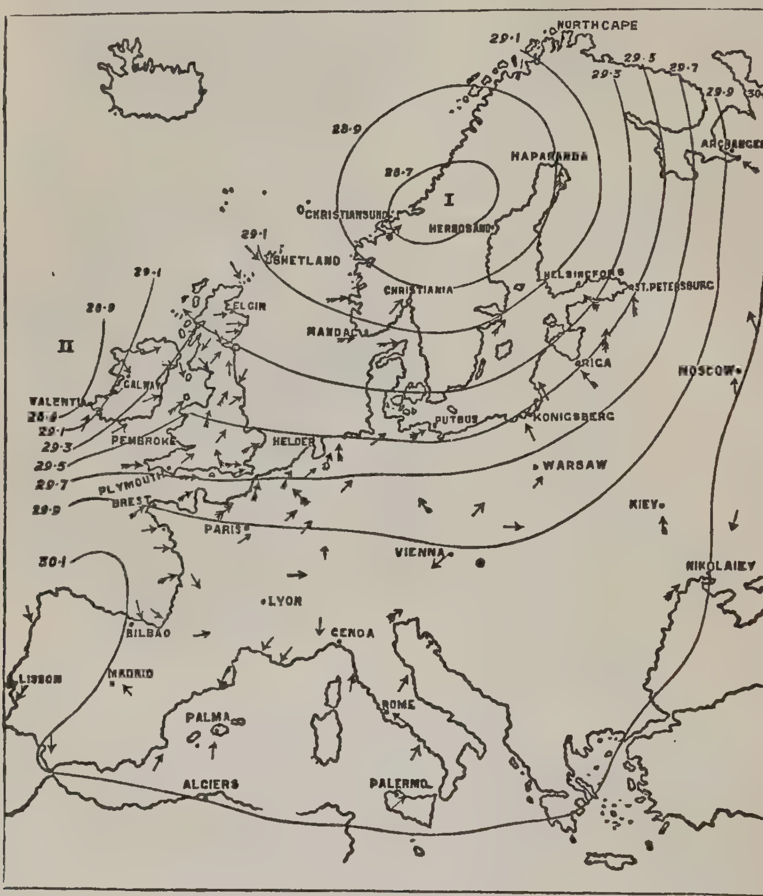


Fig. 1.—At 8 A.M., November 1, 1863.

passed over Europe at that time. The isobarometric lines, or lines shewing where, at the above hours, the height of the barometer was the same, are given for every two-tenths in the difference of the pressure. Hence, where these lines approach near each other, or crowd together, the difference of pressure, or the atmospheric disturbance, was the greatest; and the least where they are most apart—a distinction of the utmost importance in determining where the storm may be expected to rage in greatest fury. The arrows shew the direction of the wind, being represented flying with it. The force of the wind is shewn (1) by plain arrows, ⟶, which represent light and moderate winds; (2) by arrows feathered on one side only, ⟶, which represent high winds; (3) by arrows feathered on both sides, ⟶, which represent strong gales, storms, or hurricanes.

The mean atmospheric pressure, at the level of the sea, may be stated to be 29·9 inches. When, therefore, the barometer falls below 29·9, the equilibrium of the atmosphere is more or less destroyed according to the amount of the fall, and it is within this *area of low barometer* that a storm may be expected to occur. Hence, while we trace these low pressures, as they advance over the earth's surface from day to day, we trace at the same time the progress of the storms.

Form and Extent of Storm Areas.—The circular isobarometric lines on the charts represent very accurately the general shape storms assume. The area of almost every storm is either circular or

slightly elliptical, and when elliptical, the major axis of the ellipse seldom exceeds twice the length of the minor axis. Rarely in Europe, but in America less rarely, the form of storms is much more elongated. The outline is occasionally very irregular, but in all such cases the storm will be found to have parted into two or more distinct storms, which remain separate for some time and then re-unite. This circular form of storms, which an examination of some hundreds, especially in

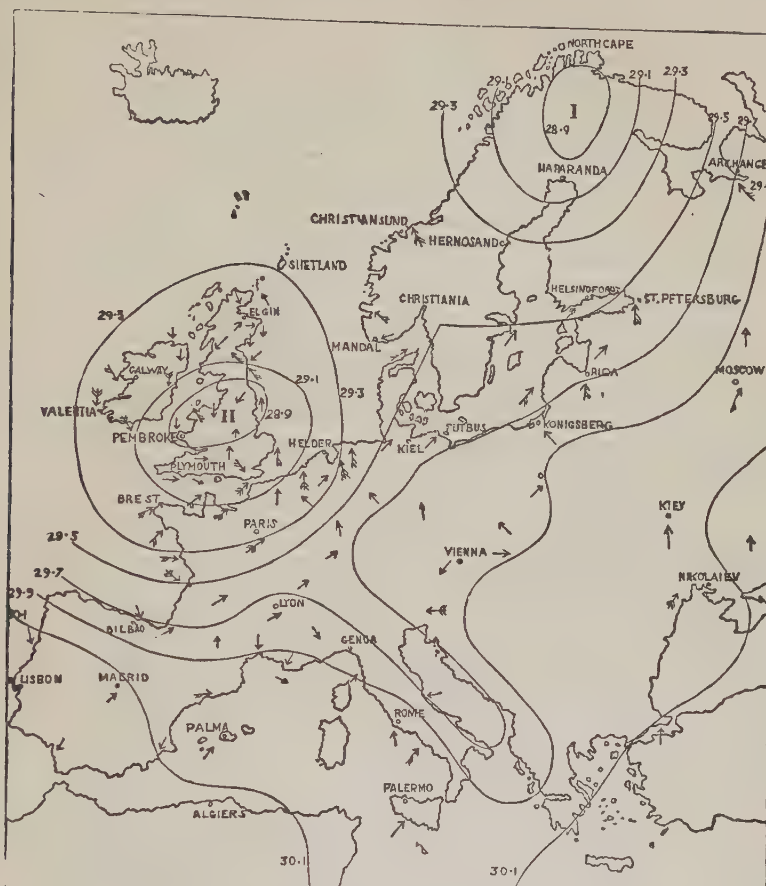

Fig. 2.—At 8 A.M., November 2, 1863.

Europe, has shewn to be their general characteristic, is a most important feature, whether as determining the practical rules for the guidance of sailors in storms, or for the forecasting of storms at particular seaports, in respect of the direction from which they may be expected to come, and the veerings of the winds during their continuance. The extent over which storms spread themselves is very variable, being seldom less than 600 miles in diameter, but often two or three times that amount, or even more. Almost the whole of Europe is sometimes overspread by a single storm at one time. The area of storms is by no means constant from day to day, but varies in size, sometimes expanding and sometimes contracting. And it is worthy of remark, that when a storm contracts its area, the central depression gives signs of filling up, and the storm of dying out. On the other hand, when it increases in extent, the central depression becomes deeper, the storm increases in violence, and occasionally is broken up into two, or even three, depressions, which become separate storms, with the wind circling round each.

Direction in which Storms advance.—It may be premised that by the direction of a storm is meant, not the direction of the wind, but the path followed by the centre of disturbance. The direction in which the progressive motion of storms takes place differs in different parts of the world—being determined by the prevailing winds. See WINDS. Thus, about half the storms of the northern Atlantic states travel from the south-west toward the north-east, and 19 out of every 20, at least, travel toward some point in the quadrant from the north-east to the south-east. Observation shews that the longer axis of the storm is almost always coincident with the direction in which the storm appears to be moving at the time. Storms do not always proceed in the same uniform direction from day to day, and though the change which occurs in the direction of their progressive motion is generally small, yet occasionally it is very great. Thus, of the many interesting features peculiar to the storm which passed over Europe in the beginning of December 1863, none were more remarkable than the sudden changes of its progressive motion. It was first

observed on the west of Ireland, from which it advanced east to Liverpool, then turned south through Worcester and Oxford to Cherbourg in France; it thence retreated north through Oxford to Shields, from which it proceeded east to Copenhagen. By the time it arrived at Copenhagen its extent was only a fourth of what it had been the previous day, and the central depression half an inch less. Twelve hours later, the atmospheric equilibrium was restored, the storm having died out on reaching the Baltic Sea. The storms of the Mediterranean follow a different course. Many of them proceed om the north to the south, influenced probably by the heated air rising from the Sahara; a considerable number proceed from the east, and pass to the westward over Greece and Italy to the Alps; while very few are observed to travel in an easterly direction. By far the greater number of the storms of North America take their rise in the vast plain which lies immediately to the east of the Rocky Mountains, and thence advance in an eastern direction over the United States; some of them, crossing the Atlantic, burst on the western shores of Europe. But the relation of the American to the European storms is not yet established, nor will be till observation has collected more facts. If once the connection be established, and the two continents united by the telegraph, the system of forecasting storms to European ports will become much more certain and complete than it is at present. The storms of the West Indies generally take their rise from near the region of calms, and tracing out a parabolic course, proceed first towards the north-west, and then turn to the north-east about 30 N. lat., many of them traversing the east coasts of North America as far as Nova Scotia. South of the equator they follow an opposite course. Thus, in the South Atlantic and Indian Ocean, they first proceed toward the south-west, and then gradually curve round to the south-east. The hurricanes of Hindustan usually pursue a parabolic path, first traversing the eastern coast towards Calcutta, and then turning to the north-west up the valley of the Ganges. The typhoons of the Chinese Seas resemble, in the course they take, the hurricanes of the West Indies. Observations are wanting from other parts of the world to determine the course of storms.

Everywhere, the course tracked out by storms is determined by the general system of winds which prevail, modified by the unequal distribution of land and water on the surface of the globe. Facts seem at present to point to this general conclusion, viz., *Storms follow the course of the atmospheric current in which the condensation of the vapour into the rain which accompanies them takes place.*

Rate at which Storms travel.—If the position of the centre of Storm I. on the 2d November be compared with its position on the 1st on the charts, it will be found to have travelled 420 miles in 24 hours, or at the rate of $17\frac{1}{2}$ miles an hour. Similarly Storm II. will be found to have travelled in the same time 400 miles, or at the rate of $16\frac{2}{3}$ miles an hour. This is about the average rate of the progressive movement of European storms. Sometimes, however, it falls as low as 15 miles an hour, and sometimes increases to 30 miles an hour. Within the tropics the onward motion of storms sometimes rises to 40 miles an hour.

Relations of Temperature, Rain, and Cloud to Storms.—The temperature increases a few degrees at places toward which and over which the front part of the storm is advancing, and falls at those places over which the front part of the storm has already passed. In other words, the temperature rises as the barometer falls, and falls as the barometer rises. When the barometer has been falling for some time, clouds begin to overspread the sky, and rain to fall at intervals; and as the central depression approaches, the rain becomes more general, heavy, and continuous. After the centre of the storm has passed, or when the barometer has begun to rise, the rain becomes less heavy, falling more in showers than continuously; the clouds break up, and fine weather ushered in with cold breezes ultimately prevails. It should be here remarked, that if the temperature begins to rise soon and markedly after the storm has passed, a second storm may be expected shortly. The rainfall is generally proportioned to the suddenness and extent of the barometric depression at the place where it falls.

Observations of the Wind.—First as to the direction of the wind. If the winds in Storm II. on the 2d November be attentively examined, they will be observed whirling round the area of low barometer in a circular manner, and in a direction contrary to the motion of the hands of a watch, with—and be this particularly noted—a constant tendency to turn inwards towards the centre of lowest barometer The wind in storms neither blows round the centre of lowest pressure in circles, nor does it blow directly towards that centre, but takes a direction nearly intermediate, approaching, however, nearer to the direction and course of the circular curves than of the radii to the centre. The greater the force of the wind is at any place, it will be observed to approach the more nearly the direction here indicated. And where the direction of the wind differs to any material degree from this general law, it is light, and consequently more under local influences, which turn it from its course. Thus, the centre of the storm being near Liverpool, the direction of the wind is south-west at Paris, south at Yarmouth, north-east at Silloth, north at Dublin, and north-west at Cork—instead of south at Paris, south-east at Yarmouth, north at Silloth, north-west at Dublin, and west at Cork, if it had blown directly to the area of lowest pressure; and west at Paris, south-west at Yarmouth, east at Silloth, north-east at Dublin, and north at Cork, if it had circulated in the direction of the isobarometric curves. Hence in this storm the winds circulate round the centre of least pressure, or, to speak more accurately, the whole atmospheric system flows in upon the centre in a spiral course. This rotatory peculiarity is common to all storms in the northern hemisphere that have yet been examined. In the southern hemisphere, a rotatory motion is also observed round the centre of storms, but it takes place in a contrary direction, or in the direction of the motion of the hands of a watch, instead of contrary to that direction, as obtains north of the equator.

To William C. Redfield we are indebted for the determination of the fact of the gyratory motion of storms, and to James P. Espy for the proof that the principal motive force acts vertically. We find by referring to Storm II. on the 2d November, that the pressure over England being much less than in surrounding countries, if the earth had been at rest, air-currents would have flowed from all directions in straight lines to England, to fill up the deficiency. The earth, however, is not at rest, but revolves from west to east; and as the velocity of rotation diminishes as the latitude increases, it is evident that the current which set out, say from Lyon to the north, would, on account of its greater initial velocity when it arrived at Paris, blow no longer directly to the north, but to a point a little to the east of north; in other words, it would no longer be a south, but a south-west wind. Again, since the

current from the north of Scotland had a less velocity than those parts of the earth's surface on which it advanced, it lagged behind, and consequently, by the time it arrived at Silloth in the north of England, had changed from a north to a north-east wind. Similarly the north-west current changed to a north, the south-west to a west, &c. The west and east currents, since they continued in the same latitude, would have blown in the same direction, if they had not been disturbed by contiguous currents. Hence in a storm the whole system of winds rotates round the centre. As a further confirmation of the truth of this theory, it is observed that when a high barometric pressure covers a limited space, the wind is always observed gently *whirling out of this area of high barometer*, but in exactly opposite directions in both hemispheres from those assumed when it blows round and in upon an area of low pressure. It follows in the northern hemisphere that as storms advance, the general veering of the wind at places lying north of the path of their centre is from north-east by north to west; and at places south of their centre, from north-east by east and south to north-west, and conversely in the southern hemisphere.

Next, as to the force of the wind: The rule is simple, and without exception—viz., the wind blows from a high to a low barometer, and with a force proportioned to the difference of the barometric pressures. Hence, where the isobarometric lines crowd together, the violence of the storm is most felt, and where they are far asunder, the winds are moderate and light. We thus see the importance of observations from a distance in forecasting the weather. To take an illustration: the importance of observations from Norway and Sweden to all seaports on the east coast of Great Britain cannot be overestimated. For if the pressure be high in Norway and low in Great Britain, violent easterly gales will sweep down on North Britain, and unless foreseen and provided against, strew the coast with wrecks; whereas, if the pressures be nearly equal, little danger need be apprehended, even though the barometer be low in Britain. As the wind nears the centre of the storm it gradually abates, till on reaching the centre a lull or calm follows. Calms and light winds also prevail along the ridge of highest barometer, or the region where the pressure is greatest, and on receding from which the pressure diminishes on each side. It may not inaptly be compared to the watershed in physical geography, since from it the wind flows away towards the places where the pressure is less.

We have stated that the progressive motion of storms varies from 15 to 40 miles per hour, which measures the time taken in passing from one place to another, but it gives no indication of the violence of the storm. This is determined by the rotatory velocity of the wind round the centre of the storm, which in Europe and America frequently amounts to 60 or 70 miles an hour continuously for some time. At Liverpool, on the 3d of December 1863, it blew in intermittent gusts with a speed of 93 miles an hour—a velocity frequently surpassed by storms within the tropics.

Of the different theories hitherto proposed, we need only refer to the rotatory and the centripetal theories. The rotatory, or, as it is commonly called, the cyclonic theory, was first proposed by Piddington, and has since been elaborated by Redfield, Reid, Dové, and others. By this theory storms are considered as revolving round an axis either upright or inclined to the horizon, while at the same time the body of the storm has a progressive motion over the surface of the globe; the barometric depression, as caused by the centrifugal force, driving the air from the centre to the circumference of the storm. Dové holds that cyclones are formed when two atmospheric currents, the equatorial and the polar, flow side by side, they being, as it were, the eddies formed at the line of junction. Observations from the numerous observatories recently established in Europe and America in no case exhibit a true cyclonic movement of the winds round the centre of the storm, but invariably show, along with the rotatory motion, a constant tendency to blow in upon the centre of the lowest pressure. Hence it is clear that the barometric depression is not caused by the centrifugal force of the storm. All the facts of the rotation of the wind are explained when it is considered as caused by air-currents flowing towards an area of low barometer along the globular surface of the earth rotating eastwards.

The rotatory character of storms was denied by Espy, who maintained that the wind blows from every quarter towards the centre of the storm, and that the central depression is caused by the development of heat, which occurs whenever the vapour of the atmosphere is condensed into cloud or rain; the heat thus developed rarefying the surrounding air and causing an upward current.

The following generalisations have been reached: (1) The area of a violent storm in America is either circular, elongated, or elliptical, is very irregular, and is from 1000 to 3000 miles in diameter. (2) Violent storms sometimes remain stationary for 4 or 5 days, but generally have a progressive movement along the surface of the earth from zero to 44 miles per hour, and within the limits of prevailing westerly winds advance from west to east. (3) The motion of rotation is much more rapid nearer the centre than in the outer whirls, but is succeeded by a lull or calm for a short time, to be followed by a recommencement with additional fury. (4) Skilful seamen, who understand the law of storms and their general course, can foresee their approach, and avail themselves of the outer winds they bring along to waft them away from the track; but inexperienced navigators are often carried across in them as in a whirlpool. (5) Great storms of rain and snow are accompanied by a depression of the barometer near the centre, and a rise near the margin. (6) For several hundred miles on each side of a storm the wind inclines towards the area of least pressure, or from the area of high barometer to the area of low barometer, and in the northern hemisphere circulates around the centre in a direction contrary to the hands of a watch. (7) On the north side of a great storm the prevalent winds are from the north-east, while on the south side they are from the south-west. (8) In the United States, on the north-east side of a storm, at a distance of over 500 miles from the area of rain and snow, the thermometer sometimes rises even 20° above the mean height.

The United States Signal Service, organised in 1870, now embraces stations from Portland to San Francisco, and from Canada to Key West. Three times daily synchronous observations are taken, reports transmitted in full by telegraph to Washington, and the results rapidly distributed to the different cities to be published. These reports are tabulated and examined by Professor Abbé, who deduces therefrom the 'probabilities,' which are also telegraphed to the press all over the country; maps are stamped exhibiting the state of the barometer, thermometer, the clouds, rain, &c., and distributed at commercial points; for a specimen, see *Harper's Magazine* for August, 1871, p. 416. See *The Atlantic Monthly*, March, 1870; *Scribner's Monthly*, Feb. 1871; Fitzroy's *Weather Book;* Loomis's *Treatise on Meteorology*, New York, 1868; and Buchan's *Handy Book of Meteorology*, Edinburgh, 1868.

STORTHING (from *stor*, great, and *thing*, court), the Legislative Assembly of Norway (q. v.). Its members are elected by certain deputies, who, in

their turn, are chosen by a constituency comprising every native Norwegian of 25 years of age, who is a burgess of any town, and possesses property or the liferent of land to the value of £30 sterling, the qualification for being elected being the same. When the storthing is in session, every member is paid an allowance equivalent to about 6*s.* 6*d.* sterling per day. When elected, the storthing meets of its own authority without any writ from the king, and divides itself into two chambers, the *Lagthing* and the *Odelsthing*, the former composed of one-fourth, the latter of the remaining three-fourths of the members.

STORY, Joseph, an American jurist and judge, was born at Marblehead, Massachusetts, September 18, 1779, was educated at Harvard College, and though admitted to the bar in 1801, gave his attention chiefly to general literature and poetry. Having published a volume in 1804, *The Power of Solitude*, and other poems, which met with no success, he bade farewell to the muses, and devoted himself to law and politics. Elected to the state legislature in 1805, he became a leader of the republican, or, as it was afterwards called, the democratic party, and defended the measures of Jefferson. In 1808, he was elected to congress, where he gave a moderate support to the war measures of Mr Madison, who, however, in 1811, appointed him associate justice of the Supreme Court of the United States, a place he filled with great credit for 34 years. In 1820, as a member of the Massachusetts constitutional convention, he advocated a property basis for the senate. In 1829, he became law professor at Harvard. His later politics were of the Federalist school of Washington and Hamilton, and these tincture his *Commentary on the Constitution of the United States.* His other writings are a work entitled *The Conflict of Laws*, and various legal treatises, which have passed through many editions. His constitutional commentaries are considered high authorities, and his legal writings and decisions are among those oftenest quoted in the higher courts of law. He died at Cambridge, September 10, 1845. His Life, by his son, William W. Story, educated a lawyer, but better known as a sculptor, was published in 1851 (2 vols. 8vo, Boston), and in 1854 appeared a collection of his *Miscellaneous Writings.*

STOTHARD, Thomas, R.A., an eminent designer and painter, was the son of a London publican, who kept the *Black Horse* in Long Acre, and was born there in 1755. He received a respectable education in different boarding-schools, and on his father's death, having shewn a predilection for the use of the pencil, was bound apprentice to a pattern-drawer in the city, but was released from his engagement before the term of expiry, and betook himself to more artistic work. His first notable effort was a series of designs for the *Town and Country Magazine*, which was followed by his imaginative compositions for Bell's *British Poets*, and the *Novelist's Magazine.* The popularity of these was so great, that for many years his services were constantly in request by the leading publishers in London. His earliest pictures exhibited at the Royal Academy were 'The Holy Family,' and 'Ajax defending the Body of Patroclus.' In 1791 he was chosen an associate, in 1794 a member, and in 1813 librarian of the academy. He died 27th April 1834. S. was really an admirable and facile illustrator. Not less than 3000 of his designs are known; but his paintings, although gracefully enough 'composed' and finely coloured, are destitute of the originality that comes from a study of nature, and painfully resemble enlarged 'illustrations' for books. Perhaps the best known and the most agreeable of the set is his 'Canterbury Pilgrims,' engraved in 1817, others are the 'Flitch of Bacon,' the 'Fête Champêtre,' and the paintings executed for the staircase at Burleigh, the seat of the Marquis of Exeter. See Mrs Bray's *Life of Thomas Stothard, R.A., with numerous Illustrations from his Works* (1851).—His son, Charles Alfred Stothard (born 1786, died 1821), acquired a great reputation as an antiquarian draughtsman.

STOU'RBRIDGE, a market-town in the county of Worcester, and 20 miles north-north-east of the town of that name, on the left bank of the Stour. It contains iron-works and glass, earthenware, and fire-brick factories. 'Stourbridge clay,' upon which the action of fire has less effect than upon most varieties of clay, is an article of export. Glass-house pots, crucibles, &c., are made of it. Pop. (1861) 8773; (1871) 9376; (1881) 9756.

STOU'THRIEFF, in the law of Scotland, means robbery committed in a dwelling-house.

STOVE, a fireplace in which the fire is generally quite shut in. The term is also applied to a room or closet heated for the purpose of drying and other operations, and to hothouses, in which the artificial heat is constantly maintained at a high temperature. Stoves for domestic purposes will be noticed under the head of Warming and Ventilation. Particular kinds of hothouse stoves are already noticed in the articles Bark-stove and Dry Stove. Stoves are also used for *forcing* fruits, so as to procure them in winter or spring. In the management of stoves, the general rule is that the temperature must never be allowed to fall below 60° F. The free access of air is, of course, desirable, but the windows are not opened unless the temperature reaches 70° F., and care must be taken that cold blasts do not enter, which are often very injurious.

STOW, or STOKE (A.-S., *stoc*, a stockaded place), a component element of many names of places, as Bristow or Bristol, Stockholm.

STOW, John, one of the earliest and most diligent collectors of English antiquities, was born in London in the year 1525. He was brought up to his father's trade of a tailor in Cornhill, but ultimately abandoned it for antiquarian pursuits. Writing in 1575, he says: 'It is now ten years since I, seeing the confused order of our late English chronicles, and the ignorant handling of ancient affairs, leaving mine own peculiar gains, consecrated myself to the search of our famous antiquities.' A patriotic sacrifice, which ought to have insured to the devoted antiquary from his king and country an old age of ease and honour, but which only brought him to want and beggary! In his 79th year, S. obtained letters patent from James I. authorising him to become a mendicant, or, as it is expressed in the state document, 'to collect amongst our loving subjects their voluntary contributions and kind gratuities.' He died April 5, 1605, and was buried in the parish church of St Andrew Undershaft, in Aldgate Ward, where his monument of terra-cotta, erected at the expense of his widow, may still be seen. The principal works of S. are his *Summary of English Chronicles*, first published in 1561, and subsequently reprinted every two or three years, with a continuation to the date of each new publication; *Annals of England*, 1580, and reprinted in 1592, to which year the annals are brought down; and *A Survey of London*, the most important of his writings, published in 1598. Besides these original works, S. assisted in the continuation of Holinshed's Chronicle, Speght's edition of Chaucer, Leland's *Collectanea*, &c. He had collected or transcribed a vast number of MSS., and much valuable information which might otherwise have

perished; and in the use of his stores he was liberal to others, while as an original historian he was faithful and impartial.

STOWE, Harriet Elizabeth Beecher, American authoress, daughter of the Rev. Dr Lyman Beecher, and wife of Rev. Professor Calvin Ellis Stowe, was born at Litchfield, Connecticut, June 14, 1812. At the age of 15, she was engaged with her elder sister, Catherine, as teacher in a girls' school in Hartford. She was married to Professor Stowe in 1836, and became a frequent contributor to periodicals, published some stories in a volume entitled *The May-flower*, and other spirited juvenile stories for the Sunday-school libraries. The ability of Mrs S. as a delineator of character, and especially of New England character, was known to many; but her full power was scarcely suspected, until, in 1851, she commenced in *The National Era*, an anti-slavery paper at Washington, a serial tale, entitled *Uncle Tom's Cabin.* When completed in 1852, it was published at Boston, and its popularity was so immense, that it soon sold in four stereotype editions to the extent of 400,000 copies. The English reprints are estimated to have circulated 500,000, and it was rapidly translated into all European and some Asiatic languages, and was extensively dramatised and illustrated. In 1853, she published a *Key to Uncle Tom's Cabin*, and made a visit to Europe, where she was received with distinguished consideration. The events and impressions of this triumphant tour are recorded in her *Sunny Memories of Foreign Lands* (2 vols. Bost. 1854). In 1856, she published *Dred, a Tale of the Dismal Swamp*, another anti-slavery story, which had a wide circulation. This was followed in 1859 by *The Minister's Wooing*, a story of New England life in the 18th c.; and in 1862 by *Agnes of Sorrento*, and *The Pearl of Orr's Island*, a New England tale. In 1868 appeared *Men of Our Times*; in 1869, *Oldtown Folks*, a picture of New England thought and feeling in the last century; and in 1869, *The True Story of Lord Byron's Life*, in the *Atlantic Monthly* and *Macmillan's Magazine*, which was severely criticised. Mrs. S. replied to her critics in *Lady Byron Vindicated*, Dec. 1869.

STOWELL, William Scott, Lord, the eldest brother of Lord Eldon (q. v.), was born at Heworth, Durham, October 17, 1745. He was educated at Newcastle; went to Oxford in 1761, remained there after taking his master's degree (1767), became a college tutor, was chosen Camden Reader of Ancient History (1774), and distinguished himself in that capacity. In 1779, he took the degree of D.C.L., removed to London, was called to the bar (1780), and admitted to the Faculty of Advocates at Doctors' Commons. Dr Johnson, whom he had accompanied from Newcastle to Edinburgh, while on his tour to the Hebrides, introduced him to the Literary Club, and he became well known in the most intellectual society of London. As an advocate, he at once obtained a large practice, and his promotion was rapid. In 1788, he was appointed judge in the Consistory Court, knighted, and nominated a privy councillor. In 1798, he became judge of the Court of Admiralty, the highest dignity to which he could attain in his own branch of the profession. Both as an ecclesiastical and admiralty judge he won high distinction. He wrote no systematic treatise or text-book, but his judgments were admirably reported, and supply the best evidence of his extensive legal learning, his sagacity, and his great literary ability. He is the highest English authority on ecclesiastical law and the law of nations, and his judgments—those, especially, relating to the rights of belligerents and neutrals—have been described as the most valuable contribution made by an English judge to general jurisprudence since the time of Lord Mansfield. As a politician, Sir William Scott was not remarkable. He represented Oxford in the House of Commons for 20 years, but he took no part in the business of parliament, although, like his brother, he was a zealous supporter of the Conservative party and the established church. At the coronation of George IV. he was raised to the peerage under the title of Baron Stowell of Stowell Park. In 1828 he retired from the bench, and in 1836 he died. Lord S. was twice married, but only one child, Lady Sidmouth, survived him.

STOW'MARKET, a small market-town of Suffolk, on the Gipping, 12 miles north-west of Ipswich. Iron, leather, paper, and gun-cotton are manufactured. The Gipping is navigable to S. Pop. (1861) 3531; (1871) 4097; (1881) 4052.

STRABA'NE, a market-town of the county of Tyrone, Ireland, on the river Mourne, 130 miles north-north-west from Dublin, with which it communicates by railway. It communicates with Londonderry, and thus with the sea, by canal and river. The chief industry is connected with the linen trade, and there is also a valuable fishery. The population, in 1861, was 4146, of whom 2513 were Roman Catholics, 838 Protestants of the Established Church, 713 Presbyterians, and the rest dissenters of other denominations; in 1881, 4196.

STRABI'SMUS. See Squinting.

STRA'BO, an ancient geographer, born at Amasea in Pontus, about the middle of the 1st c. B.C. By the mother's side he was of Greek descent, and also closely connected with the Mithridatidæ; of his father or his father's family nothing is known. How the name Strabo ('squint-eyed') must have originated, is obvious, but whether any of the family were so called before him is uncertain. S. was well educated under the grammarians, Tyrannio of Amisus in Pontus, and Aristodemus of Nysa in Caria, and the philosopher Xenarchus of Seleucia in Cilicia. He does not appear to have followed any professional calling, but to have spent his life in travel and study, from which it may safely be inferred that he was possessed of wealth, or at least of considerable means. He died some time after 21 A.D., but how long, we have no evidence to shew. S.'s *Geography* is a work of great value in those parts especially which record the results of his own extensive observation. 'Westwards,' he says in a passage in the 2d Book, 'I have travelled from Armenia to the parts of Tyrrhenia adjacent to Sardinia towards the south, from the Euxine to the borders of Ethiopia. And perhaps there is not one among those who have written geographies who has visited more places than I have between these limits.' Yet it must not be supposed that he describes with equal accuracy or fulness all the countries of whose geography he treats. Some he seems to have visited hurriedly, or in passing elsewhither; others he knows like a native. For example, his accounts of Greece, particularly the Peloponnesus, are meagre in the extreme, and of many of the obscurer regions he writes chiefly from hearsay. He makes copious use of his predecessors, Eratosthenes, Artemidorus, Polybius, Posidonius, Aristotle, Theopompus, Thucydides, Aristobulus, and many other writers now lost to us, but he strangely depreciates the authority of Herodotus, and quotes few Roman writers except Fabius Pictor and Julius Cæsar. The *Geography* comprises 17 books, of which the first two are introductory, the next eight are devoted to Europe, the six following to Asia, and the last to Africa. The style is pure and simple. The *editio princeps* of S. appeared at Venice in 1516.

the latest and best is that by Gustaf Kramer (Ber. 1844, *et seq.*).

STRADELLA, Alessandro, a Neapolitan musical composer of the 17th c., of much celebrity, both in respect of his influence on the music of that age, and of the tragical history of his life and death. His works, which consist of numerous airs, duets, cantatas, madrigals, an oratorio, and an opera, contributed largely to form the taste of the succeeding composers, particularly Purcell, Clari, Steffani, and Alessandro Scarlatti. S. was renowned for his exquisite voice and polished manner; and when engaged in Venice, instructing a young lady of rank, who lived in a criminal intimacy with a noble Venetian, the musician and his pupil became mutually enamoured, fled to Rome, and were married there. They were traced thither by two bravos in the employ of the Venetian, who discovered them in the church of San Giovanni Laterano, where S. was assisting at the performance of an oratorio of his own; and both assassins, it is said, were so captivated with his voice and strains, that they at once abandoned their object, and betrayed to him the plot in which they had been engaged. Pursued by other bravos to Turin, S. was stabbed, but not mortally, when lodged in the palace and under the protection of the Duchess of Savoy. Some years afterwards, however (about 1670), he went to Genoa, in pursuance of an engagement to compose an opera, and the day after his arrival, both he and his wife were mortally stabbed in their bedchamber by the emissaries of their unrelenting persecutor.

STRADE'LLA, a city of Northern Italy, 10 miles south-east of Pavia, with 6977 inhabitants. It is situated on the slope of a hill. S. was formerly a fortified city, depending on the bishops of Pavia.

STRAFFORD, Thomas Wentworth, Earl of, eldest son of Sir W. Wentworth of Wentworth, Woodhouse, Yorkshire, was born April 13, 1593. In 1611, he married Lady Margaret Clifford, eldest daughter of the Earl of Cumberland. Subsequently, he was chosen member of parliament for the county of York. In 1615, he was appointed *Custos Rotulorum* for the West Riding of the same county. Being again returned to parliament for Yorkshire in 1621, shortly after his election he took up his residence in London. Slighted by the Duke of Buckingham, who then ruled the court and cabinet of Charles I., Wentworth signalised himself as an opposer of the administration. In 1626, he was made sheriff of his county, with the view of preventing him from attending parliament. So resolutely did he oppose the arbitrary royal loan, exacted in the following year, that the government deemed it advisable to put him in prison. But Buckingham was little aware of the energy of his opponent. S., having obtained his release, came to the following parliament, resolved to make his power felt both by king and minister. He spoke eloquently on the question of grievances, and was conspicuous in obtaining the royal assent to the Petition of Right. He was obviously a man worth gaining; and his patriotism, if it had any genuine element, was, unhappily, not strong enough to withstand the temptation now held out to his personal ambition. With his elevation to the peerage, as Baron Wentworth, in 1628, he seems not only to have lost all solicitude for popular liberty, but openly to have become its most determined enemy. As President of the 'Council of the North,' he seems to have abused his powers not only for political purposes but often simply to gratify his own pride. The legality of the jurisdiction exercised by the council, created by Henry VIII., was altogether very doubtful; and interdicts against it were at various times applied for from the Courts at Westminster. S. declared openly that he would 'lay by the heels' any judge presuming to interdict the council from the exercise of such powers as he chose to hold that it possessed. Nevertheless, this was done by Judge Vernon. In 1631, S. was made Deputy of Ireland, and in 1639, Earl of Strafford and Lord Lieutenant of Ireland. According to his views, that country belonged to the crown by right of conquest, and neither the natives, nor the descendants of the conquerors themselves, had any rights which could interfere with its sovereignty. His government was of despotic violence, but the administration of justice, in ordinary cases, was prompt and vigorous. Outrage was suppressed, and commerce flourished under his strong hand. Understanding fully the feelings, policy, and resources of the party to which he had originally belonged, S. had matured a vast political scheme, to which, in his confidential correspondence, he gave the expressive name of 'Thorough.' His object was to do in England what Richelieu was doing in France—to make Charles as absolute as any continental monarch; to put the estates and personal liberty of the whole people at the disposal of the crown; to deprive the courts of law of all independent authority; and to punish with merciless severity all who murmured against the government, or who applied to any tribunal for relief from its despotism. Happily, the people of England were too strong for him. On his entering the House of Peers, on the meeting of the Long Parliament in 1640, the message from the House of Commons was called in, and Mr Pym, in the name of the Commons of England, impeached 'Thomas, Earl of Strafford,' of high treason. This course was afterwards abandoned, and the Commons proceeded by bill of attainder. It passed the House on April 21, 1641. Immediately after, it passed in the House of Lords, and received the royal assent. S. certainly merited his fate, but nothing can excuse the cowardice of the king. The earl was executed on May 12, 1641. The attainder was reversed in the reign of Charles II., and his son succeeded to the honours.—See Hallam's *Constitutional History;* Macaulay's *History of England,* with authorities cited in these works.

STRAIN, the name given to any one of the periods into which a musical composition is divided by double bars, the strain being further subdivided into periods, sections, phrases, and feet.

STRAITS SETTLEMENTS are the British settlements in the Straits of Malacca, comprising Singapore (q. v.), Malacca (q. v.), and the Prince of Wales Island (q. v.), or Penang, including the province of Wellesley. Each of these settlements is described in its own place, and its area and population given. They were transferred in April, 1867, from the Indian government to that of the Secretary of State for the Colonies. The entire area is about 1225 sq. m. Pop. (1861) 282,831; (1881) 423,384.

STRA'LSUND, a fortified town and seaport of Prussia, province of Pomerania, is situated on a narrow strait called the Strela Sunde, which divides the mainland from the island of Rügen. It forms an island, partly surrounded by the sea and partly by large pools of salt water, and is connected with the mainland by three bridges. The natural strength of the place is greatly increased by formidable fortifications. Right in front of the harbour lies the fortified island of Dänholm. S. has narrow but pretty regular streets, and many of the houses are finely gabled, which gives the town a quaint and ancient look. S. carries on a large export-trade,

especially in malt and corn, and has manufactures of leather, sugar, starch, mirrors, and cards. Pop. (1880) 29,492. S. was founded in 1209 by Prince Jaromar of Rügen, became a member of the Hansa, and rapidly rose into importance. During the Thirty Years' War, it was unsuccessfully besieged (1628) by Wallenstein; and after being, with some alternations of fortune, in the possession of Sweden for about 200 years, it finally passed to Prussia in 1815, but still retains a considerable amount of its ancient municipal independence.

STRANGE, Sir Robert, eminent as an engraver, was born in Pomona, one of the Orkney Islands, July 14, 1721. After some little abortive study of law at Edinburgh, he was apprenticed to an engraver there of the name of Cooper, under whom he made rapid progress. In 1745, he deserted art for arms, joining the army of Charles Edward, not so much from enthusiasm in his cause, as to find favour with a Miss Isabella Lumisden, who would only consent to be gracious to him on that romantic condition. The only exploit recorded of him in this relation is not one of glorious battle. After the final collapse of the adventure, he was in hiding in the house where Miss Lumisden resided; and on occasion of its being searched by the soldiery, he shrouded himself under the folds of her ample petticoat, and thus cleverly evaded detection. It is extremely satisfactory to know that very soon after the lady requited his heroism by marrying him. He now went abroad with his wife, and at Paris he prosecuted his art under the tutelage of the celebrated Le Bas, and afterwards of Descamps. In 1751, he returned to Britain, and settling himself in London, speedily attained the very highest rank in his profession. On again going abroad in 1760 to execute plates of the most famous pictures of the old masters, his eminence was recognised by the academies of Paris, Rome, Florence, Bologna, and Parma, all of which conferred on him the honour of membership; and subsequently in 1787, the distinction of knighthood testified to the high favour he found in his own country. After a life of honourable and successful industry, he died on 5th July 1792, leaving a handsome fortune to his family. To this day, S. is ranked at the very head of British engravers, and his reproductions of the nobler specimens of the old masters are much prized by the connoisseur. In the very amusing work entitled *Memoirs of Sir Robert Strange, Knight, Engraver, and of his Brother-in-law, Andrew Lumisden, Private Secretary to the Stuart Princes* (2 vols. 1855), by James Dennistoun of Dennistoun, a full account will be found of him, with an intelligent criticism of his chief works.

STRANGLES is a contagious eruptive disorder peculiar to young horses. It is ushered in by sore throat and cough, a muco-purulent nasal discharge, and the eruption of a swelling in the space between the branches of the lower jaw. In about ten days, this swelling comes to a head, bursts, and in favourable cases the patient is soon well again. From exposure to cold, poverty, or other causes, the swelling, however, occasionally appears in less favourable situations, as about the glands lying within the shoulder, in those of the groin, or even in those of the mesentery. Such irregular cases are apt to be protracted, accompanied by much weakness, and sometimes prove fatal. Bleeding, physic, and irritant dressings are injurious. Good food and nursing, with fomentations to the throat, and steaming of the head, favour the healthier maturation of the swelling. When there is debility, coax the animal to eat by offering him at short intervals small quantities of scalded oats, malt, bran, or green food, and allow him several times daily a pint of sound ale.

STRANGULATION may be defined to be 'an act of violence in which constriction is applied directly to the neck, either around it, or in the fore part, so as to prevent the passage of air, and thereby suddenly suspending respiration and life.' —Taylor's *Principles and Practice of Medical Jurisprudence*, 1865, p. 673. This definition, as Dr Taylor observes, obviously includes Hanging (q. v.). *Hanging* has been already briefly noticed in a special article, but the medico-legal relations of this and the other varieties of strangulation have still to be considered. The primary cause of death from hanging has been considered in the article just referred to, but it is necessary to add that if a person who has hanged himself has been cut down sufficiently soon to allow of the respiratory process being restored, he is by no means safe: death often taking place from secondary effects at various periods after the accident. The most prominent morbid appearance in these instances was extreme congestion of the brain.

When the suspension of the body has not continued for much more than five minutes, and the parts about the neck have not suffered violence, there is a probability that resuscitation may be established; although many cases are recorded, when after only a few minutes' suspension, it has been found impossible to restore life. It is believed that death takes place very rapidly, and without causing any suffering; the violent convulsions that are so often observed being similar to those which occur in epilepsy. A man named Hornshaw, who was on three occasions resuscitated from hanging—a feat which he performed in London for the amusement of the public—stated that he lost his senses almost at once; and other persons who have been restored state that the only symptoms of which they were conscious were a ringing in the ears, a flash of light before the eyes, then darkness and oblivion. The treatment to be adopted after the patient has been cut down may be briefly summed up as follows: Exposure to a free current of air, cold affusion if the skin is warm, the application of ammonia to the nostrils, of mustard poultices to the chest and legs, and of hot water to the feet, and the subsequent abstraction of blood if there should be much cerebral congestion; artificial respiration should also be tried if the above means fail to re-establish the respiratory process. From the post-mortem appearances, together with circumstantial evidence, the medical practitioner is not unfrequently called upon to decide such questions as these: Was death caused by hanging, or was the body suspended after death? Was the hanging the result of accident, homicide, or suicide? For the full discussion of these questions, the reader is referred to chapter 53 of Dr Taylor's volume. In case of strangulation from other causes than that of hanging, the post-mortem symptoms are similar, but the injury done to the parts about the neck is commonly greater. In manual strangulation, the external marks of injury will be in front of the neck, about and below the larynx; and if death has been caused by a ligature, the mark round the neck will be circular, whereas in hanging it is usually oblique. The internal appearances are much the same as in the case of hanging.

STRA'NGURY (Gr. *strangx*, that which oozes out, *oureo*, I micturate) is perhaps to be regarded as a symptom rather than a disease. It shews itself in a frequent and irresistible desire to pass water, which is discharged, however, in very small quantity, and whose passage from the bladder is accompanied with

scalding and cutting pains along the course of the urethra. The pain often extends to the bladder and even to the kidneys, and is sometimes so severe as to implicate the lower bowel (the rectum), and to produce the straining condition known as *Tenesmus*. It is usually caused by irritating substances in the urine, especially by *cantharides* or Spanish flies (whose irritant principle is liable to find its way into the renal secretion, whether the above-named drug is taken internally or merely applied to the skin as a blistering agent), and by oil of turpentine, when administered internally in small doses, and is generally present in cases of gravel. Severe as the affection is, it is very transitory, and yields readily to treatment. After the removal of the cause, if it can be recognised and the removal is possible, a drachm of laudanum in a wine-glassful of starch mucilage should be thrown into the lower bowel, and mild mucilaginous draughts (of barley-water, for example) should be freely given in order to render the urine less irritating. The warm-bath is also useful, and if it cannot readily be obtained, hot local fomentations often tend to relieve the pain and allow the urine to pass more freely.

STRANRAE'R, a royal and parliamentary burgh, seaport, and market-town of Wigton, Galloway, at the head of Loch Ryan, 6 miles north-east of Portpatrick. There are no manufactures, the town depending almost wholly on the agricultural interest. The town is well known for the valuable oyster fishery carried on in Loch Ryan. In 1872, 439 vessels, of 64,191 tons, entered and cleared the port. Agricultural produce and cattle, leather, and shoes are exported. Pop. of royal burgh 3615; of parliamentary burgh, which unites with the Wigton burghs in sending a member to the House of Commons, 6342.

STRAP, in Carpentry, an iron band fixed round two or more timbers, sometimes with branches along each, to hold them all firmly together.

STRA'SBOURG (Ger. *Strassburg*), an important city of Germany, province of Alsace-Lorraine, was formerly capital of the French dep. of Bas Rhin, but in 1871 was ceded to Germany. The city stands at the confluence of the Ill and the Brusche, and not far from the left bank of the Rhine, 89 miles north of Basel, and 312 miles east of Paris by railway. The streets are irregular, the houses old-fashioned. The citadel, built by Vauban, 1684, was demolished by the Germans during the bombardment of 1870, but in 1873 they began to rebuild it, and this, in conjunction with a system of 12 detached forts being erected at several miles' distance from the walls, will make the position one of great strength. The most celebrated building is the minster, or cathedral, founded in 504 A. D., and, along with the cathedrals of Cologne and Freiburg, one of the most sublime specimens of Gothic architecture. It is rich in sculpture. The spire is 466 feet in height, or 33 feet higher than St Peter's at Rome, and is only surpassed in altitude by two edifices of human construction—the pyramid of Cheops and the cathedral of Vienna. It has a remarkable astronomical clock representing the planetary system. For an account of the cathedral, see Schreiber, *Das Münster in S.* (Freib. 1828). Other notable structures are the Protestant church of St Thomas, with the tomb of Marshal Saxe, and various monuments to distinguished S. scholars; the *Temple Neuf*, or New Temple, the synagogue of the Jews, the Town-house, the Palace of Justice, the arsenal, the episcopal palace, and the theatre. The university of S. was the only complete university in France—i. e., the only one which has the full complement of faculties—besides that of Paris. It was founded in 1621, became specially famous in the branches of medicine and philology, went to the ground during the great Revolution, and its place was supplied by an *Ecole Centrale*. In 1803, a Protestant academy was established with 10 chairs, for teaching theology, philology, philosophy, and history. Five years later, Napoleon founded an imperial academy, with faculties of law, medicine, physical science, and philosophy; and in 1819, a partial fusion of these academies took place, greatly to the benefit of both. On the conclusion of the Franco-Prussian war in 1871 the university was reorganized, and in May of the following year (1872) was solemnly opened.

The famous library of S., consisting of nearly 200,000 volumes, and rich in *Incunabula* (q. v.), was entirely destroyed by fire during the bombardment in 1870, but has been to some extent replaced by a library of about 120,000 volumes, contributed by the Germans. The trade of S., especially its transit-trade, is very extensive, and it has a great variety of manufactures—beer, ham, sausages, fat-liver pies, watches and clocks, leather, cottons, woollens, silks, cutlery, musical and mathematical instruments, jewellery, brandy, potash, tobacco, &c. The Basel and Baden railways, the railway to Paris, and the communication with Rotterdam and London by means of the Rhine steamers, as well as with the Danube and all the great rivers of France by means of canals, have greatly added to its facilities for conducting commerce. The country round about S. is fertile and carefully cultivated, with beautiful gardens, mansions, and villages. Pop. of the town in 1880, 104,501, of whom nearly one-half are Catholics.

S., the *Argentoratum* of the Romans, was extant before the time of Cæsar, but is first mentioned by Ptolemy. The Romans had a manufactory of arms here. In the 5th c., it appears to have received the name of *Strata-Burgum* or *Strata-Burgus*, perhaps from the invading Franks, whence the modern German Strassburg and the French Strasbourg. It became a free town of the German Empire, and in 1681 passed with the rest of Alsace into the hands of the French, under whom its population and prosperity have greatly increased. On Sept. 28, 1870, Strasbourg capitulated to the Germans, and 451 officers and 17,000 men laid down their arms.

STRA'TEGY is defined by military writers to be the science of manœuvring an army out of fire of the enemy, as *tactics* is the art of managing it in a battle, or under fire. Strategy is the greater science, as including all those vast combinations which lead to the subsequent available displays of tactics. A good strategist has to attend to the establishing of his bases and dépôts, although some brilliant generals have dared to act without these last aids—notably, Sherman in America in 1864, and Wellington in 1813, advancing from Portugal through Spain into France. The strategist must know how to diffuse the influence of his arms over a broad area, while yet holding his force well in hand to strike crushing blows. Such was Wellington's Salamanca campaign; in which, though retreating himself to his former base, he compelled the French to evacuate Valentia.

Strategy must not be confounded with stratagem, although there is relationship between the two. Stratagem is any device for deceiving the enemy as to the point or strength of an attack. Such are ambuscades, feints, bugle-calls to imaginary troops, concealment of infantry by clouds of cavalry, and many other efforts.

STRA'TFORD, a thriving town of Essex, on the Lea, 3 miles east of London. It is the seat of various and extensive manufactures. There are flour-mills, distilleries, and chemical works. In

the town and its suburbs, many London merchants have built residences. The prosperity of the town has been much increased by its connection with the Eastern Counties Railway. Pop. (1851) 10,586; (1861) 15,994; (1881) 38,489. On the opposite side of the Lea is the parish of Stratford-le-Bow, with about 30,000 inhabitants.

STRATFORD-UPON-AVON, a municipal borough and township of England, in the county of Warwick, and 8 miles south-west of the town of that name, is situated on the right bank of the river Avon. Pop. (1881) 8053. The town is neatly built, and has quite a modern look, most of the old houses having disappeared. Some trade is carried on in corn and malt. S. is the birthplace of Shakspeare. The house in which he was born is still preserved, and is visited by enthusiastic pilgrims from all quarters of the world. The great poet is buried in the parish church.

STRATFORD-DE-REDCLIFFE, STRATFORD CANNING, VISCOUNT, English diplomatist, is son of a London merchant, and cousin of the celebrated George Canning. He was born 1788, educated at Eton, and entered himself of King's College, Cambridge, in 1806, but left in 1807, on receiving an appointment as précis writer in the Foreign Office. He was appointed secretary of embassy at Constantinople in 1809. He returned to Cambridge in 1812 for the purpose of resuming his studies, and took the degree of M.A. He was sent as envoy to Switzerland in 1814. About this time he published an ode full of spirit and power, entitled *Buonaparte*. It is called by Lord Byron a 'noble poem.' In 1820, he went as plenipotentiary to the United States, and remained at Washington three years. In 1824, he was sent on special missions to St Petersburg and Vienna. In 1825, his introduction to Eastern diplomacy commenced with his appointment by Mr Canning, then foreign secretary, as ambassador extraordinary to the Sublime Porte. Here his good offices were warmly exerted on behalf of the Greeks. In 1831, he was accredited with a special mission to Turkey, to fix the boundaries of the new kingdom of Greece, and to settle the treaty in virtue of which Otho ascended the Greek throne. He went to Madrid and Lisbon on a special mission in 1832. He had previously sat in the House of Commons for Old Sarum and Stockbridge during a brief interval in his diplomatic career. In 1834, he was elected for King's Lynn, which he represented until 1841, when, having twice refused the governor-generalship of Canada, he was appointed by the government of Sir Robert Peel ambassador at Constantinople. Here his influence was strenuously exerted in the cause of civilisation and progress. In 1852, the Derby administration recommended the crown to confer upon him the title and dignity of Viscount. When the long-standing quarrel between the Greek and Latin monks in Palestine involved the powers of Europe in the struggle, S. remembered how the Emperor Nicholas of Russia had, from 1829 to 1853, sought to establish a predominant influence, excluding all others, over the Porte, with the view of settling the future destinies of Turkey, to the profit of Russia when the propitious juncture arrived. At the time when Prince Menchikoff was sent to Constantinople upon a mission from the czar, S. was absent in England on leave. He returned to Constantinople in April, 1853, and prepared to resist M.'s demands. The keenly contested diplomatic struggle between S. and the Russian ambassador extraordinary is narrated with dramatic power by Mr Kinglake in his *Invasion of the Crimea*, who calls S. the 'Great Eltchi.' S.'s influence with the Porte prevailed, for, to adopt the words of Mr Kinglake, 'as though yielding to fate itself, the Turkish mind used to bend and fall down before him;' and he placed on England the responsibility of a defensive alliance with the sultan against the czar. As Russia would not withdraw her troops from the principalities, the sultan declared war against Russia, and France and England came to the aid of the Porte. S. retired from the Turkish embassy in 1858 upon a pension. He has since taken a frequent part in the debates of the Upper House on questions of foreign policy. He was created Knight of the Garter in 1869.

STRATH, a Gaelic word signifying a broad valley, is often prefixed in the north of Scotland to the names of rivers, as Strathearn, Strathallan, Strathnairn, Strathspey, in each of which cases it signifies the open valley through which the river flows. In such cases, however, as Strathmore (great valley), it simply signifies a valley-like depression. In the south of Scotland, the word is not used, and the Northumbrian word *dale* is made use of to express the same thing, as Clydesdale, Annandale, Teviotdale, Tweeddale.

STRATHA'VEN, a town of Scotland, in Lanarkshire, about a mile west of Avon Water, and 14 miles south-east of Glasgow. On the north side is the picturesque ruin of Avondale Castle, and from 5 to 7 miles south-west are the battle-fields of Drumclog and Loudoun Hill. The more recently built part of the town is neat and spacious. Pop. about 40,000, chiefly engaged in weaving and trading in cheese and cattle.

STRATHCLY'DE. In the 8th c., the ancient confederacy of the Britons was broken up into the separate divisions of Wales and English and Scottish Cumbria. Scottish Cumbria, otherwise called S., thenceforth formed a little kingdom, comprising the country between Clyde and Solway, governed by princes of its own, and having the fortress-town of Alclyde or Dumbarton for its capital. Becoming gradually more and more dependent on Scotland, it was annexed to the Scottish crown at the death of Malcolm I., on failure of the line of native sovereigns. Edgar bequeathed S. to his youngest brother David, again separating it from the crown of Scotland, which went to his intermediate brother, Alexander I. David held it throughout Alexander's reign in spite of that king's opposition, and on the death of Alexander without issue in 1124, it was permanently reunited to the kingdom of Scotland under David I.

STRATHMO'RE (the Great Valley), the most extensive plain in Scotland, is a low-lying tract extending across the country from Dumbartonshire north-east to Stonehaven in Kincardineshire, is bounded on the north by the great mountain-rampart of the Highlands, and on the south by the Lennox, the Ochil, and the Sidlaw Hills, and is 100 miles long and from 5 to 10 miles broad. In a stricter sense, however, S. proper extends only from the neighbourhood of Perth to that of Brechin in Forfar, a distance of about 40 miles.

STRATHSPEY', a kind of Scottish national dance slower than the reel, which is said to derive its name from having been first practised in the district called Strathspey.

STRATIO'TÉS, a genus of plants of the natural order *Hydrocharideæ*, having a 2-leaved spathe with numerous barren flowers, one female flower in each spathe. *S. aloides*, popularly called WATER SOLDIER, is common in lakes and ditches in the east of England. It is a singular plant with numerous leaves, which are strap-shaped and spring from the root, from which also springs the two-edged flower-stem,

bearing the spathe with beautiful and delicate white flowers. In autumn the whole plant disappears, the root alone remaining at the bottom of the water;

Water Soldier (*Stratiotes aloides*).

from which a number of young plants arise in spring, filling up ditches, so that nothing else can grow in them. It is a very ornamental aquatic plant.

STRA'TUM, pl. *strata* (Lat. strewn or spread out), the term applied by geologists to the layers into which most of the rocks that form the crust of the earth are divided. It implies that the layers have been spread out over the surface, and that they were formed in this way we may infer from the deposits that are now taking place in lakes and seas into which rivers laden with muddy sediment empty themselves.

All the aqueous rocks, which cover so large a proportion of the earth's surface, are stratified. They were formed from the abraded materials of older rocks (aqueous or igneous), which have been washed down and rearranged. The kind of rock produced depended upon the material to which the carrying agent had access. Fine mud would produce shales, sand sandstones, and calcareous matter limestones. In a section, these different kinds of rocks are frequently found to interchange within a short space. This is produced either by the water obtaining different materials, or changing its velocity. Thus the fine sediment which has fallen from slowly flowing water may be covered by a layer of sand brought down by a flood, and this again may have spread over it a covering of shells and corals, and such changes may go on alternately for an indefinite period. Each of the different beds composed of the same kind of material is called a stratum. Thus, in the series mentioned, there would be a 'stratum' of clay, one of sand, and then one of calcareous matter. An assemblage of strata having a common age is called a 'formation,' and this term is also extended to rocks which agree in their composition or origin. Thus we speak of stratified and unstratified, aqueous and igneous, freshwater and marine, primary and secondary, metalliferous and non-metalliferous formations. As a formation is composed of many different beds, so a stratum is frequently made up of several 'laminæ' or 'layers.' The laminæ have a more or less firm cohesion, but the strata easily separate from each other. Sometimes the cohesion of the laminæ is so great, that it is as easy to split the rock against as with the grain. In such compact rocks the lamination is obscure, or altogether imperceptible in fresh specimens, but whenever they are exposed to the influence of the weather, it becomes obvious. The laminæ have been produced by short interruptions in the deposition, similar to what might be the result of tidal or other intermittent action. The degree of cohesion may be the result of rapid succession in the acts of deposition, but it is frequently produced by metamorphic action subsequent to deposition. The planes of stratification want the complete coalescence characteristic of lamination; when the contiguous layers are closely united, it is the result of the adhesion of two bodies, and not of their coalescence into one.

STRAU'BING, a town of Lower Bavaria, on the right bank of the Danube, 25 miles south-east of Ratisbon, lies in a very fertile valley, and carries on a river-trade in corn, cattle, and horses. In a little chapel here there is a monument to Agnes Bernauer (q. v.). Pop. 11,408.

STRAUSS, DAVID FRIEDRICH, author of the famous *Leben Jesu*, was born on the 27th January 1808, at Ludwigsburg, in Würtemberg. His education was begun in his native town, and completed in the theological seminaries of Blaubeuren and Tübingen. In 1830, his head filled with Hegel's philosophy and Schleiermacher's theology, he entered on the simple life of a country pastor, but already in the following year he was in Maulbronn acting as professor in the seminary, and went thence to Berlin for six months to continue his Hegelian studies, and hear the lectures of Schleiermacher. Returning to Tübingen in 1832, he became *repetent* in the theological seminary, and in the next years held also philosophical lectures in the university as a disciple of Hegel. Known as yet only to a narrow circle, he became all at once a man of mark by the publication, in 1835, of his *Life of Jesus critically treated* (2 vols. Tüb.; 4th ed. 1840; translated into English, 1846). In this work, written from the point of view of a Hegelian philosopher, and designed only for the learned, he attempted to prove the received gospel history to be a collection of myths gradually formed in the early Christian communities, and sought, by an analytical dissection of each separate narrative, to detect, where it existed, a nucleus of historical truth free from every trace of supernaturalism. The book made a real epoch in theological literature, and produced a violent excitement in and out of Germany, calling forth numberless replies from opponents, frightening many by its bold disregard of consequences back into the ranks of orthodoxy, and stirring up others to similar investigations. The first consequence to the author was his dismissal from his academical position in Tübingen, and transference to the Lyceum of Ludwigsburg. He resigned the new post, however, very soon in 1836, and retired into private life at Stuttgart, to have leisure to defend himself. In 1837, he published his *Streitschriften* against his opponents; and in 1838, *Zwei friedliche Blätter*, a more conciliatory exposition of his views. Early in 1839, he was called by the Board of Education in Zürich to be Professor of Dogmatics and Church History in the university; but the step raised such a storm of opposition amongst the public, that the proposition had to be dropped, and even the government itself had to resign in the same year. Thrown back on his literary labours, S., who had published during the year his *Charakteristiken und Kritiken*, sent forth shortly afterwards his second great work, *Die Christliche Glaubenslehre*, a review of Christian dogma 'in its historical development and its struggle with modern science' (Tüb. 1840—1841). This formed a natural sequel to the purely critical

investigation of the origins of Christianity in the first work. When S., after a long period of silence, next appeared on the literary field, it was no longer as a professed theologian. In 1847, he drew attention by a work entitled, *Der Romantiker auf dem Throne der Cäsaren, oder Julian der Abtrünnige*, full of direct allusions to the political situation of the day. His fellow-townsmen put him forward as a candidate for the German revolutionary parliament of 1848, but he was unable to stand against the clerical influence brought to bear upon the country-people of the district. His speeches on this occasion were published under the title of *Six Theologico-political Popular Addresses*, and his native place compensated the defeat by sending him as its representative to the Würtemberg Diet. From this position, however, when he unexpectedly displayed conservative leanings, and incurred a vote of censure from his constituents, he retired before the end of the year. A life of the Swabian poet Schubart (1849), and another biographical work, *Christian Märklin, a Picture of Life and Character from the Present* (1851), giving an insight into his own mental development, were his next literary efforts, before another period of silence. His third period of activity was opened in 1858 by a remarkable life of the Reformer, Ulrich von Hutten, followed up by the publication of Hutten's *Dialogues* in 1860. These books, though primarily of strictly historical interest, were nevertheless calculated for the present state of religious affairs in Germany, and contained fiercely contemptuous denunciations of the tactics of the reactionary party in the church. A collection of miscellaneous *Minor Writings* appeared in 1862, and a new *Life of Jesus, composed for the German People*, in 1864 (Eng. translation, 1865). The title of the work indicates its popular cast, the peculiar features of it being a long critical statement of the labours of others in the same field down to the present day, and an attempt to construct a life out of all the positive results that have been gained. The mythical hypothesis is retained, but applied differently. Still later publications, which appeared in 1865, are *Der Christus des Glaubens u. der Jesus der Geschichte* (Berlin), a criticism of the newly published lectures of Schleiermacher on the life of Jesus, and a brochure, *Die Halben u. die Ganzen*, directed against Schenkel and Hengstenberg. The polemic against Schenkel, Professor of Theology in Heidelberg, a leader of the liberal party in the church of Baden, and author of the *Charakterbild Jesu* (1864), arose out of an earlier notice of this book by S. In 1872 he published his last work, *Der alte und der neue Glaube* (translated under the title *The Old Faith and the New: a Confession*), in which he endeavours to prove that Christianity as a system of religious belief is practically dead, and that a new faith must be built up out of a scientific knowledge of nature. The literary, critical, and polemical powers of S. were of the highest order. No more effective prose than his has been written in Germany since the days of Lessing. He died Feb. 8, 1874.

STRAWBERRY (*Fragaria*), a genus of plants of the natural order *Rosaceæ*, suborder *Roseæ*, tribe *Potentillidæ*, remarkable for the manner in which the receptacle increases and becomes succulent, so as to form what is popularly called the fruit; the proper fruit (botanically) being the small *achenia* which it bears upon its surface. The genus differs from *Potentilla* (q. v.) chiefly in having the receptacle succulent. The calyx is 10-cleft, the segments alternately smaller; the petals are five; the style springs from near the base of the carpel. All the species are perennial herbaceous plants, throwing out runners to form new plants; and the leaves are generally on long stalks, with three leaflets, deeply toothed. One South American species has simple leaves. Only one species, the WOOD S. (*F. vesca*), is truly a native of Britain. It is common in woods and thickets. Its fruit is small, but of delicious flavour. Another species, the HAUTBOIS S. (*F. elatior*), is not unfrequently to be seen in woods and hedges, but has probably escaped from gardens. It is really a native of North America. The many kinds cultivated in gardens are regarded as varieties of these species, and of the CAROLINA S. (*F. caroliniana*), the PINE S. (*F. grandiflora*, or *F. ananas*), and the CHILI S. (*F. chilensis*), American species, the leaves and fruit of which are larger than those of the Wood Strawberry. In no genus, however, are the species more uncertain to which the cultivated kinds are to be referred. Some of these are remarkable for the large size of the fruit. New varieties are continually coming into notice, and the utmost care is necessary to keep the larger and finer varieties from degenerating. The cultivation of the S. is most extensively carried on in Britain and America. New kinds are produced from seed; but plantations of strawberries are generally formed of the young plants, which are abundantly produced by runners. The rows are from eighteen inches to two feet apart, according to the kind. The finest fruit is said to be produced when the plants are kept distinct from each other in the rows, but this is not generally done. Tiles are sometimes placed around the plants and under the fruit; and it is an old English practice to lay straw between the rows, to preserve the fruit from rotting on the wet ground, from which the name S. has been supposed to be derived; although more probably it is from the wandering habit of the plant, *straw* being a corruption of the Anglo-Saxon *strae*, from which we have the English verb *stray*. S. beds require to be renewed after a few years. Strawberries are often forced in hothouses, in order to produce the fruit at a very early season. The uses of the S. as a dessert fruit and for preserves are well known. There is no more wholesome fruit.

The ALPINE S. (*F collina*), a native of Switzerland and Germany, differs considerably from the other kinds in its taller stems and more erect manner of growth. The fruit, which is either red or white, is not very large, but is produced in great abundance, and, unlike other strawberries, parts from its calyx almost on being touched. The Alpine S. continues to produce fruit long after the other kinds.

The INDIAN S. (*F. indica*), a native of the Himalaya, requires only a little protection in Britain from severe frost, and with this care grows luxuriantly and produces fruit in abundance. The flowers are yellow, not white, as in other strawberries, and are not produced upon common flower-stalks rising from the centre of the plant as in the other species, but upon single-flowered stalks, which spring from the axils of the leaves upon the runners. The fruit is very beautiful, not hanging down like other strawberries, but growing with its apex upwards. It is not, however, of good quality.

STRAW-MANUFACTURES. The industrial applications of the straw of wheat are of great commercial importance, especially that of plaiting, which is one of the oldest arts practised by mankind, many specimens having been found in the tombs of the ancient Egyptians, and mention being made of plaiting by Herodotus and other early writers. The earliest notice we have of its systematic use in Europe as an article of clothing is in the records of the reign of Mary, Queen of Scots, who we are told, observed that the peasants of Lorraine

wore hats made of straw plait, and that this manufacture was beneficial to them, and she consequently conceived the idea of introducing it into Scotland, which was done about the year 1652, but without much success. Her son, James I., however, carried it into England, where it soon throve, and has been from that time a permanent branch of industry. It was first regularly established in Bedfordshire, which has ever since been the chief seat of the trade.

At first, the plait was what is called *whole straw;* that is, the straw was cut into suitable lengths without knots, and merely pressed flat during the operation of plaiting, and so it continued until the reign of George I., when it was in great demand for ladies' hats, and some plait was made of split straw. Since that time, this kind has been chiefly used, and a much improved method has been substituted for the clumsy one of using a common knife for splitting it. The instrument now employed (fig. 1) is made of steel, and consists of a number of little square blades set in a circular manner around the stem, which at one end terminates in the point *a*, and at the other is bent and fixed into the handle *b*. The point, *a*, being inserted into the hollow of the straw, is pressed forward, and cuts it into as many strips as there are blades in the cutting-tool; these vary in number according to the fineness of the work to be produced.

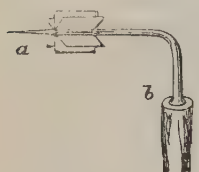

Fig. 1.

It is found that the fine straw-plaiting, which is now produced better in England than in any other country except Italy, can only be made from one or two varieties of wheat, that called the White Chittim being generally preferred, and next to it the Red Lammas, which only succeed as a straw-crop upon the light rich soils of the more southern of the midland counties. The harvesting is a matter of great anxiety, as the straw is liable to many injuries from wet and other causes. The value of this crop can be best understood by the fact that an acre will yield from 25 to 40 bushels of wheat, and from 15 cwts. to a ton of straw, which, when in good condition, is worth £7 or £8.

The crop is bought up by straw-factors, who employ people to draw the straw, and remove the ears, which are all cut off by hand for thrashing. The straws are afterwards cut into lengths, and cleared of the outer sheath or leaf; they are then sorted into various thicknesses by an apparatus consisting of a series of sieves about eight inches in diameter, arranged as in fig. 2, *a, a, a, a;* the boys who usually do this work hold a handful on end

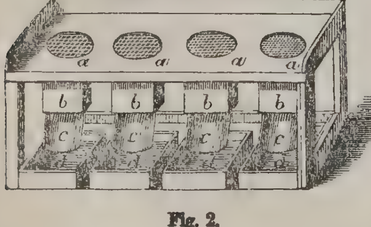

Fig. 2.

over the first sieve, which has the narrowest spaces, and the thinnest straws only fall through it; they are next placed on the second, and so on to the last. As they fall through each successive sieve, they pass down the hollow shafts *b, b, b, b*, by the shoots of tin or sheet-zinc *c, c, c, c*, into the boxes *d, d, d, d*, from which they are removed and tied into bundles ready for the splitters, who next take them in hand and reduce them to strips of the sizes required.

The plaits are made by women and children in their own cottages, and are collected by the dealers and sold in the Luton and Dunstable markets, in which the chief part of this business is transacted. They are very various in pattern, and are sold by the *score* of 20 yards, the prices ranging from 2*d.* to 3*s.* per score for the ordinary kinds, but very fine plaits have been known to fetch as high as £3 to £4 per score.

It is computed that 70,000 persons are employed in this trade, of whom nearly 60,000 are females and boys, and that they produce annually about 12,000,000 scores, or 240,000,000 yards of plait. The plait is made up into bonnets and hats chiefly at Luton and Dunstable, and sent up to the London warehouses for sale, whence they are sent to all parts of the world. A large trade is also done in the fine plaits of Tuscany; the Leghorn plaits are very fine, and fetch high prices.

Besides its value for plaiting, straw is now much used in the manufacture of Paper (q. v.).

STRELITZ, more properly *Streltzi* (arquebussiers), the ancient Russian militia-guard, first raised by Ivan Vassilevitch the Terrible, in the second half of the 16th century. At that time, and for long afterwards, they were the only standing army in Russia, and at times amounted to between 40,000 and 50,000 men. They were located at Moscow in time of peace, in a quarter of the capital which was set apart for them, and being the bravest and most trustworthy troops in the army, were made objects of special favour and distinctions. But like all such petted corps, the Roman Prætorians, the Turkish Janizaries, and the Egyptian Memluks, their general turbulence, frequent revolts against the government (notably during the Demetrian insurrections), and incessant conspiracies, rendered them more formidable to the Russian government than to external enemies. The S. having, at the instigation of the Grand Duchess Sophia and the chiefs of the Old Muscovite party, revolted against Peter the Great, that iron-handed ruler caused them to be decimated (1698) in the great square of Moscow, and the remainder to be banished to Astrakhan. The feeble remnant still manifesting their characteristic turbulence and disloyalty, Peter exterminated them almost completely in 1705. Few Russian families at present can claim kindred with the old Streltzi, but to this the family of Orloff (q. v.) forms a prominent exception, being descended from a Strelitz who was pardoned by Peter the Great while the axe was being raised over him.

STRENGTH OF MATERIALS. The strength of materials depends upon their physical constitution—viz., their form, texture, hardness, elasticity, and ductility.

The resistance of materials in engineering works is tested in reference to various strains; such are—1. Extension or tension; 2. Compression or crushing; 3. Transverse or cross strain; 4. Shearing strain; 5. Torsion or twisting strain.

1. *Extension.*—When a rod is suspended vertically, and a weight attached to its end tending to tear it asunder, all its fibres act equally, and its strength evidently depends on the strength of the individual fibres and their number, that is, the area of cross-section of the rod. The following table

gives the resistance to *rupture* of some of the most common materials:

	Per Square Inch.
Fine sandstone,	200 lbs.
Brick,	300 "
Common lime,	50 "
Portland cement,	240 "
Deal (timber),	5 tons.
Cast iron (ordinary),	6½ "
" Stirling's toughened,	12½ "
Wrought iron, boiler-plate,	20 to 24 "
" bars,	25 "
Cast steel,	60 "
Ropes (hemp), four-fifths ton per pound-weight per fathom.	

With regard to the elongation of materials under tensional strain, it has been observed that up to a certain limit, which is different for different substances, the elongation is proportional to the extending force, a physical truth the promulgation of which is due to Hocke (q. v.); up to this limit also the body nearly recovers its original form on the removal of the force: this limit is called the limit of elasticity. When this limit is passed, the permanent elongation or destruction rapidly increases until rupture takes place.

The extension of wrought iron is about $\frac{1}{10,000}$th of its length per ton of strain per square inch, and that of cast iron $\frac{1}{5000}$th. The limit of elasticity of wrought iron is attained under a strain of 12 tons per square inch; and in the case of American pine ½ ton per square inch.

2. *Compression or Crushing Strain.*—The strength of pieces of stone, wood, or iron, whose height is small in proportion to their area, and which absolutely crush under the strain, is proportional to the area of their horizontal section. The following table gives the resistance to crushing of some of the more common materials:

Cast iron,	50 tons per square inch.
Wrought iron,	16 " " "
Brickwork,	30 tons per square foot.
Sandstone,	200 " " "
Limestone,	490 " " "
Deal,	450 " " "
Oak,	650 " " "

Up to a certain strain, which is called the limit of elasticity, the diminutions in length of the body are proportional to the compressing force; and are practically the same in amount as the elongations in the case of tensional forces. In the case of wrought iron, the limit is 12 tons per square inch; after that strain, its shape and proportions become permanently altered; and where these are of consequence, as in most practical cases, we come to the limit of its utility, which is reached when the load is about 16 tons per square inch. It then oozes away beneath additional strain, as a lump of lead would do in a vice.

The mode of ultimate failure of cast iron is quite distinct from that of wrought iron. It crushes suddenly by the sliding off of the corners in wedge-shaped fragments, being a crystalline mass, without sufficient ductility to allow of its bulging horizontally; the angle of rupture at which these wedges slide off being tolerably constant, and varying from 48° to 58°. The limit of elasticity is attained in cubes of deal under a compression of 100 tons per square foot; and in those of oak, 150 tons per square foot.

Pillars, round or square, may be divided into three classes—1. Those whose height is not more than 5 times their diameter; 2. Those whose height is between 5 and 25 times their diameter; 3. Those whose height is at least 25 times their diameter. The first follow the same laws as cubes or pieces of small height above discussed, and are absolutely crushed; their strength being proportional to their cross section. The second are broken across, partly by crushing and partly by bending. The third give way purely from bending as with a transverse strain, and their strength is found by experiment to be directly proportional to the fourth power of their diameter, and inversely proportional to the square of their length. Thus, in the case of two long pillars of equal length, but of which one has its diameter double that of the other, the strength of the former will be 16 times that of the latter; from which will be apparent the advantage of the tubular form for pillars, as it gives a large diameter, combined with lightness.

In the case of long columns whose length is 25 or more times their diameter, if we represent the strength of a long cast-iron column of any dimensions by 1000, the strength of a wrought-iron column of the same dimensions will be 1750; of cast steel, 2500; of Danzig oak, 110; of red deal, 80.

3. *Transverse or Cross Strain.*—When a beam fixed at one end is loaded with a weight at the other, it is bent from its original form, and takes a curved shape. The fibres on the upper or convex side of the beam are extended, and those on the under or concave compressed; while at the middle of the beam, there are fibres which are neither extended nor compressed, where the compression ends and the extension begins: this surface of fibres is called the neutral surface. As long as the beam is not strained beyond the limit of its elasticity, the extensions and compressions for a given strain are nearly equal, and therefore the neutral surface passes through the centre of gravity of the cross section of the beam.

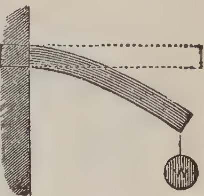

Fig. 1.

If we strain the beam beyond this limit, and approach the breaking strain, the extensions and compressions are no longer equal, and therefore the position of the neutral surface is not readily determined. For example, in the cases of stone and cast iron, the amount of compression is much less than that of the extension, and in the case of timber, greater. Also the extensions and compressions are no longer proportional to the strains. From these causes the position of the neutral axis, and the amount of strain on the different parts of the cross section at the moment of rupture, cannot be determined by theory.

Different theories have been proposed to determine the relative strength of similar beams, while their absolute strength is left to experiment. That of Galileo consists in supposing the beam incompressible, and that it gives way by extension turning round the lower edge, each point of the section giving an equal resistance before rupture. That of Mariotte and Leibnitz supposes the beam in like manner to turn round its lower edge, but considers that the resistance given out by each point of the section is proportional to its distance from that edge.

The theory now generally adopted consists in supposing the extensions and compressions to continue up to the point of rupture proportional to the strains, as is actually the case up to the limit of elasticity, and therefore, that the beam turns round a neutral axis, passing through the centre of gravity of the cross section, the force given out by each point being proportional to its distance from the neutral axis. This last theory is found to give the best results in the case of timber and

wrought iron, especially wrought iron arranged in the forms usual in girders. The second represents nearly the method of failure of stone, and the first that of cast iron.

Though none of these theories give accurate results, they yet give us means of determining, from particular experiments, the strength of any other beam whatever. For example, these theories agree in giving the strength of a rectangular beam to be proportional to the area of cross section multiplied by the depth, and inversely proportional to the length of the beam, since the strain increases directly as the length. This, when expressed mathematically, is

$$W = C\frac{bd^2}{l} \qquad \text{(I.)}$$

Where w = breaking weight in tons.
b = breadth of beam in inches.
d = depth of beam in inches.
l = length of beam in inches.
C = a constant number for beams of the same material, to be determined by experiment.

This result is borne out by experiment—that is to say, the constant C being determined by experiment on one beam, the strength of any other is found by multiplying its breadth by the square of its depth and by the constant C, and then dividing by its length. In the case of a beam supported at each end and loaded by a weight in the middle, as in fig. 2, the strength is also given by the formula,

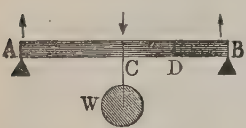

Fig. 2.

$$W = c\frac{bd^2}{l} \qquad \text{(II.)};$$

but c, in this case, is 4 times the value of C in the formula for a beam loaded at one end. The truth of this may be seen from the consideration that the beam ACB, fig. 2, may be treated as if it were two beams, each fixed at the point C at one end, and pressed upwards by the reaction of the supports at A and B, their other ends. This reaction is evidently equal to $\frac{W}{2}$; so that the breaking weight of the whole beam ACB, supported at both ends, resolves itself into that of the beam CB or AC of length $\frac{l}{2}$, acted on by the weight at one end $\frac{W}{2}$; this by formula (I.) is,

$$\frac{W}{2} = C\frac{bd^2}{\frac{l}{2}}$$

$$\text{or, } W = 4C\frac{bd^2}{l} = c\frac{bd^2}{l};$$

$$\text{therefore, } c = 4C \text{ or } C = \tfrac{1}{4}c.$$

Experiments on the transverse strength of beams are generally made in the manner of fig. 2. The following table, from experiments by Mr Barlow, gives the value of c for beams supported at each end and loaded in the middle:

	Tons.
Cast iron,	$13\frac{1}{2}$
Wrought iron,	12
English oak,	$2\frac{1}{7}$
Red pine,	$2\frac{4}{5}$

These numbers when substituted in the formula give the breaking weight, $\frac{1}{3}$d of this will be the safe load in practice. The transverse strength of cast iron is considered so good a test of its value, that in specifications of iron-work, it is generally required to be of such a quality that a bar of it, of certain dimensions, will bear a specified weight at the centre; for example, 'that a bar of it, 42 inches long, 2 inches deep, and 1 inch wide, set on bearings 36 inches apart, shall bear, without breaking, 30 cwt. suspended in the middle.' If a beam be loaded uniformly over its length, as in fig. 3, it will bear twice as much as if the load be condensed at the centre, as in fig. 2. Also, if the load be placed some distance from the centre, as at D, fig. 2, the load it will bear is to the load borne at the centre, C, inversely as the rectangle of the segments into which the beam is divided by the point of application of the load are to one another, that is, as AC × CB or $\frac{l^2}{4}$ is to AD × DB, from which it follows that it will bear less weight at the centre than at any other point.

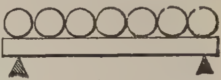

Fig. 3.

Since the strength of a rectangular beam is proportional to the square of the depth, multiplied by the breadth, it is evident that by increasing the depth and diminishing the breadth we shall, up to a certain limit, increase the strength of a beam without increasing its weight; for example, let A and B, fig. 4, be the sections of two beams, of which A is 2 inches broad and 2 deep, and B 4 inches deep and 1 inch broad, they are of the same sectional area —viz., 4 square inches, but the strength of B is to the strength of A as $4^2 \times 1$ is to $2^2 \times 2$, or as 16 to 8, that is, 2 to 1, that is to say, B is twice the strength of A. Hence arises the advantage of the double T forms so generally used in iron girders, fig. 5, the strength of which forms are proportional to the area of the top or bottom plates multiplied by the depth. For a beam of the form in fig. 5, loaded as in fig. 2, the following formula will give the breaking weight:

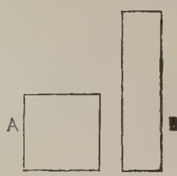

Fig. 4.

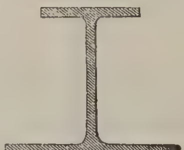

Fig. 5.

$$W = C\frac{ad}{l}$$

Where a = the area of the top or bottom flange in square inches.
C = 4 times the destroying load per square inch of the material, under direct tension or compression in tons.
d = depth of the beam in feet.
l = length between supports in feet.
W = breaking weight at the centre in tons.

For cast-iron beams, when the area of the bottom flange is made 6 times that of the top, which has been found by experiment to be the best arrangement, and the strength is measured by the tensional strain, supported by the bottom flange, that is, $6\frac{1}{2}$ tons per square inch,

$$C = 6\tfrac{1}{2} \times 4 = 26 \text{ tons.}$$

For wrought-iron beams,

$$C = 4 \times 20 = 80 \text{ tons for the lower flange,}$$
$$\text{and } C = 4 \times 16 = 64 \text{ tons for the upper flange.}$$

Another way of throwing the great body of the material at a distance from the neutral axis is, to make it into the shape of a tube or hollow cylinder. Let B be the section of a hollow cylinder, the thickness of whose walls is represented by the shaded ring; and A be the section of a solid cylinder of the same material. If the area of A is equal to that of the ring in B, the two cylinders will contain the same quantity of matter, but B will be stronger than A, nearly in proportion as cg is longer than dg.

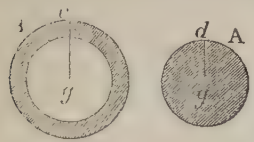

Fig. 6.

The principle of hollow structure prevails both in nature and art, wherever strength and lightness have to be combined. It is seen in the stems of plants, especially of the grasses; the bones of animals are also hollow, and those of birds, where great lightness is required, are most so. A feather, with its hollow stem, is perhaps the best instance of the union of strength and lightness that could be given. In art, again, we have hollow metal pillars; and sheet-iron for roofing and other purposes is *corrugated*, or bent into ridges and furrows, to give it depth. Each ridge or furrow is, as it were, half a tube, and resists bending with twice or thrice the energy it would if flat.

The most striking application of the principle of hollow structure is seen in tubular bridges. Fig. 7 represents a section of the tube of the Conway Bridge. The object being to resist a vertical strain, the form is made rectangular, and the chief mass of the material is thrown into the top and bottom. The tube may, in fact, be considered as an immense beam or girder constructed on the principle of fig. 5, the top and bottom being the two flanges, and the two sides serving to connect them, instead of the one rib in the middle. As it is constructed of plate-iron, the top requires more metal than the bottom, in order to resist the compression; but instead of putting the metal into one thick plate, or into several plates laid the one on the other, it is made to form a set of minor tubes or cells, which give additional stiffness and strength to the whole tube. The floor, in like manner, contains cells. Each of the tubes over the Conway is 24 feet high, 14 feet wide (outside), and 420 feet long, and weighs 1300 tons; yet these enormous hollow beams sustain not only their own weight, but the heaviest railway-trains without sensible deflection.

Fig. 7.

Fig. 8 represents an ingenious contrivance for strengthening the wooden beams supporting a bridge. An iron rod, fixed to the beam AB at the two ends, is kept at a distance by struts c, c'. The beam cannot now be bent downwards without stretching the rod; which thus has to bear the tensive strain, while the beam itself sustains only the compressive strain.

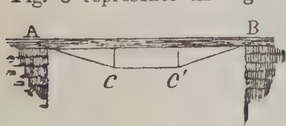

Fig. 8.

Another way of removing part of the strain from a girder, is to fix a king-post, c, and two oblique pieces on its upper side, as in fig. 9. The whole is now one composite girder; and when any weight, f, bears upon it, the whole of the compressive strain is thrown upon the pieces a, b, and only the tensive strain is left for the beam to sustain.

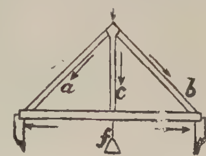

Fig. 9.

When a beam AB is fixed at one end, and loaded at the other, the strain is greatest at B, and is less at other points, as c, c', in proportion as Ac, Ac', the levers at which it acts, are less than AB. The beam may therefore be made to taper off towards the end, and we may determine the exact form the beam should have, in order to be equally strong at every point. For supposing the breadth uniform, the strength increases as the squares of the depths $c'd'$, cd, while the strain increases as the levers Ac', Ac; and thus, if $Ac : Ac' :: cd^2$ to $c'd'^2$, the strengths are equal at those points. This proportion will always hold good, if the curve of the beam is that of a parabola; and, accordingly, this is the shape given to the beams of steam-engines.

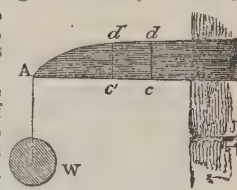

Fig. 10.

In beams supported at both ends, the strain is greatest in the middle; girders are therefore made strongest in the middle, and taper towards the ends.

4. *Shearing Strain.*—This force is called into play when a plate is cut by shears, or when a riveted or bolted joint is torn asunder, in which case the rivets are sheared across. The effect of it is to cause the particles in one plane to slide over those in another; this is resisted by their mutual coherence, and the magnitude of the resistance depends on the number of the particles, that is, on the area of cross section of the body sheared. The following laws are the result of experiment—1. The ultimate resistance to shearing is proportional to the area of section of the bar sheared. 2. The ultimate resistance of any bar to a shearing strain is nearly the same as the ultimate resistance of the same bar to a direct longitudinal strain.

5. *Torsion.*—If one end of the axle or shaft of a wheel is immovably fixed, and a power acts at the circumference of the wheel (or at the end of a lever or winch), the power may be so increased as to twist the shaft asunder at its weakest point. If a shaft A has twice the diameter of another shaft B, there will be four times as many fibres in the section of fracture of A, to resist the twist, as in that of B. But as the separation takes place by the one end of the fracture turning round upon the axis of the shaft, making the ends of the separating fibres describe circles, those fibres that are furthest from the centre will have the greatest power of resistance, and the sum of their moments, of their united effect, will be in proportion to their mean distance from the centre. This mean distance in A is twice that in B; therefore, the resistance in A is 2×4, or 8 times the resistance in B. Generally, *the strength of shafts to resist torsion is as the cubes of their diameters.* The torsive strengths of shafts 1 inch diameter, and with weights acting at 1 foot leverage, being found by experiment for different materials; the strength of shafts of other dimensions is found

from these 'constants' by multiplying by the cube of the diameter, and dividing by the length of the lever. It is evident that the torsive strength of a hollow shaft will be greater than that of a solid one of the same quantity of material, on the same principle that its transverse strength is greater. The rule used by Boulton and Watt for calculating the diameters of their wrought-iron shafts was as follows :

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{120 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

This is found to make the shafts rather too light; and the following variation gives safer practical results :

$$\text{Diameter of shaft in inch.} = \sqrt[3]{\frac{240 \times \text{horse-power.}}{\text{Revolu. per minute.}}}$$

STREPSI'PTERA (Gr. twisted-wings), an order of insects called RHIPIPTERA (Gr. fan-winged) by Latreille, but first established by Kirby. The first-known species were observed by Rossi, and referred by him to the order *Hymenoptera*. The order S. consists of a small number of species, very singular in structure and habits, apparently forming an aberrant division of the *Coleoptera*, most nearly allied to the *Meloidæ*. The species are all small, and in their larval state live parasitically in the bodies of bees and wasps. Their natural history has been the subject of much attention since they were discovered; but much still remains obscure. The species form the two genera *Stylops* and *Xenos*.

STRE'TCHING-COURSE, in Masonry or Brickwork, is a course in which the stones or bricks are placed with their longest sides along the face of the wall. The stones are called *stretchers*, as those placed at right angles to them with their end exposed are called *headers*.

STRE'TTO (Ital. bound), in Music, a term which signifies that the movement to which it is prefixed is to be performed with rapidity gradually accelerating towards the close.—The term *stretto* is also applied to the recurrence in a fugue of the subject in one part before it has come to a close in another. See FUGUE.

STRI'Æ, the fillets between the flutes of columns, pilasters, &c.

STRICKLAND, AGNES, an English authoress, the daughter of Thomas Strickland, Esq., was born at her father's seat, Reydon Hall, near Southwold, in Suffolk, in the year 1806. She was the third daughter of a family of six daughters and two sons, nearly all of whom have contributed something to the literature of our time. Her first compositions were mostly in the poetical vein, and consisted of anonymous contributions to periodicals. About the year 1825, however, she published, in conjunction with her sister Susanna (afterwards Mrs Moodie), a volume of *Patriotic Songs;* which was followed, in 1826, by a little volume bearing her own name exclusively, and entitled *Worcester Field, or the Cavalier; a Poem, in Four Cantos, with Historical Notes*, which was favourably received by some of the reviews. *Worcester Field* was followed by *The Seven Ages of Woman, and other Poems* (Lond. 1827); and this by *Demetrius, a Tale of Greece, in Three Cantos* (Lond. 1833), written in the metre of Byron's *Corsair*. In 1836, she published a little volume entitled *Floral Sketches, Fables, and other Poems;* republished in 1861. With this the list of Miss A. S.'s poetical works ends. Among her prose works are : *The Rival Crusoes*, published without date ; *The Pilgrims of Walsingham, or Tales of the Middle Ages, an Historical Romance* (2 vols., 1835) ; *Tales and Stories from History* (1836) ; *Alda, the British Captive* (1841) ; *Historical Tales of Illustrious British Children* (1847 ; new ed. 1858) ; *Historic Scenes and Poetic Fancies* (1850) ; *Old Friends and New Acquaintances* (2 series, 1860—1861). All these, however, are but of small import in comparison with her well-known work, *Lives of the Queens of England from the Norman Conquest, with Anecdotes of their Courts*, in 12 vols. (Lond. 1840—1848 ; new ed., 8 vols., 1851—1852). In this work, the materials for which she discovered by diligently ransacking among the treasures of the British Museum and other great public repositories of historic documents, Miss S. was largely assisted by her sister Elizabeth, an assistance which she gratefully acknowledges in her Preface. It was dedicated to Queen Victoria; and as each volume successively appeared, its picturesque style and anecdotical character made it a general favourite, especially among that class of readers whose object in reading history is rather amusement than philosophical instruction. At the same time, it must be owned that in these *Lives* she has added materially to our stock of historical information. Miss S.'s *Lives of the Queens of England*, concluding with the biography of Queen Anne, were followed by the *Lives of the Queens of Scotland and English Princesses connected with the Regal Succession of Great Britain*, in 8 vols. (Edin. and Lond. 1850—1859) ; and these by her *Lives of the Bachelor Kings of England* (Lond. 1861), and *Lives of the Tudor Princesses, including Lady Jane Grey and her Sisters* (Dec. 1868). In 1865 she published a novel, entitled *How will it End?* and in 1866 *Lives of the Seven Bishops.* In 1871 she received a pension of £100. She died July 13, 1874.

STRI'CTURE is a term employed in Surgery to denote an unnatural contraction, either congenital or acquired, of a mucous canal, such as the urethra, œsophagus, or intestine. When, however, the affected part is not mentioned, and a person is stated to suffer from stricture, it is always the urethral canal that is referred to. Contraction of this canal may be either permanent or transitory; the former is due to a thickening of the walls of the urethra, in consequence of organic deposit, and is hence termed organic stricture; while the latter may be due either to local inflammation or congestion, or to abnormal muscular action: the first of these varieties may be termed inflammatory or congestive stricture; and the second, spasmodic stricture. The last-named form seldom exists except as a complication of the other kinds of stricture. There are two principal causes of organic stricture—the first being inflammation of the canal, and the second injury by violence. Inflammation is by far the most common cause, and gonorrhœa is the common agent by which it is excited. Not unfrequently, stimulating injections thrown into the urethra, with the view of checking the gonorrhœal discharge, excite an inflammatory action, which gives rise to stricture. Fortunately, it is only in exceptional cases that a stricture results from inflammation of the urethra, the inflammation, in the great majority of cases, terminating by resolution, and leaving the canal as healthy as before the attack. It is when the complaint assumes a chronic character that it most commonly lays the foundation of stricture. Stricture from the second cause arises from such cases as falling across spars, scaffolding, ladders, &c., or on some sharp object which punctures the perinæum, as from earthenware vessels which break under the sitter.

The earlier symptoms of stricture are a slight urethral discharge and pain in the canal, behind the seat of the stricture, at the time of micturition. The stream of urine does not pass in its ordinary

form, but is flattened or twisted; and as the disease advances, it becomes smaller, and ultimately the fluid may only be discharged in drops. The straining efforts to discharge the urine often induce Tenesmus (q. v.).

As the case advances, the urine becomes alkaline and ropy, and deposits a precipitate when allowed to stand; and attacks of complete Retention (q. v.) occur with increasing frequency. But these symptoms are not in themselves sufficient to establish the presence of stricture. It is necessary to examine the urethral canal with a Catheter (q. v.) or Bougie (q. v.), to ascertain whether an organic obstruction exists, whether one or more strictures are present (as many as eight have been recorded, although four are rare; and one is the most common number), and their calibre. The treatment of organic stricture is too purely surgical to be discussed in these pages: it is sufficient to state that its object is twofold, viz., first, to restore the natural calibre of the canal, so far as this can be safely effected; and secondly, to maintain this patency, after it has been established.

Spasmodic stricture may occur from any of the following causes: the presence of organic stricture or of inflammation of the mucous membrane; from an acrid condition of the urine; from the administration of cantharides, turpentine, &c.; and from the voluntary retention of urine for too long a time. The treatment consists in the removal of the causes as far as possible, and the hot bath. The inhalation of chloroform sometimes gives immediate relief; and several cases are recorded in which, when the spasm occurred periodically, it was cured by quinine. Inflammatory or congestive stricture commonly arises when a recent purulent discharge from the urethra has been checked by external cold or wet. The patient complains of heat, fulness, and soreness in the perinæum; the passage of the urine is extremely painful, the stream being small, and ceasing before the bladder empties. The treatment is much the same as that for Retention of Urine (q. v.).

STRIE′GAU, a walled town of Prussia, province of Silesia, and government of Breslau, is situated on Striegau Water, 32 miles west-south-west of Breslau. It has manufactures of woollens and linens. Pop. (1867) 8561.

STRIKE, a term borrowed by geologists from the German *streichen*, to extend, and adopted with the technical meaning it has in that language. It is applied to the direction of the outcrop of a stratum —the line which it makes when it appears on the surface of the earth. This line is always at right angles to the dip of the bed. The angle of dip and the direction of strike are determined by a clinometer and compass. A perfectly horizontal stratum can have neither dip nor strike.

STRIKES. See COMBINATION.

STRING-COURSE, a thin projecting course of stone or brickwork in a wall, generally ornamented with a moulding, and made to go round windows or other openings in the wall.

STRINGE′NDO, a term used in Music to denote a gradual acceleration in the time.

STRI′NGHALT is a peculiar catching up of the horse's limbs, usually of one or both hind limbs. It is most noticeable when the animal is first brought out of the stable, when he is excited, or made to turn suddenly round; it is a variety of chorea or St Vitus's dance. Although a serious eyesore, it does not interfere with usefulness, but is quite incurable.

STRO′BILA. See TAPE-WORMS.

STRO′MBIDÆ, a family of gasteropodous molluscs, of the order *Pectinibranchiata*, nearly allied to *Buccinidæ* (Whelks, &c.) and *Muricidæ*. The shell has a canal, the external lip of which, as it attains maturity, becomes more or less dilated, and is marked with a sinus, whence the head issues when the animal comes out. The foot is narrow and small, but is employed in active leaping movements, during which the shell oscillates from side to side. The species are numerous, and are mostly inhabitants of tropical seas. Some of them are among the largest of molluscs. *Strombus gigas* is the largest known univalve. It is found in the West Indies, on reefs in shallow water, and is fished both

Fountain-shell (*Strombus gigas*).

for the table and on account of the shell. Great numbers of the shells are imported into Britain; 300,000 have been brought to Liverpool in a year. They are sometimes called Fountain-shell, from their occasional use as a garden ornament. Their chief use, however, is by cameo-makers, by whom they are valued for their solid and delicately tinted substance. A shell sometimes weighs four or five pounds. Pearls of a delicate pink colour are sometimes found in this shell. The *Strombi* are sometimes called wing-shells, from the dilated margin of the lip.

STRO′MBOLI, one of the group of the Lipari Islands (q. v.), the most north-easterly of the group, is about 12 miles in circumference, circular in shape, and contains 1452 inhabitants. It is wholly of volcanic formation, and rises to the height of 3100 feet above sea-level. On its western side is a volcano of considerable activity. Sulphur and pumice-stone are gathered in large quantities, and among the chief agricultural products are cotton, wine, and excellent fruits.

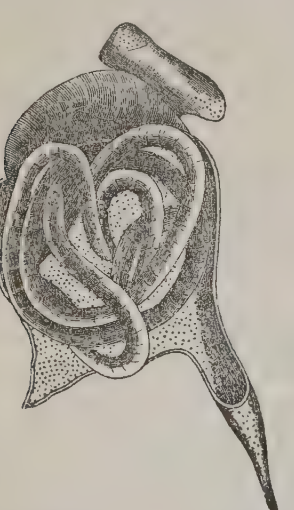
STRO′MNESS. See ORKNEY ISLANDS.

STRONGY′LIDÆ, a family of nematode worms, possessing the following common characters. The body is round, and sometimes very much elongated, and almost thread-like. The mouth is round, oval, or triangular, and situated at the extreme anterior end of the body. The tail of the male is commonly furnished with a bursa, usually emitting two spicules. The whole family is parasitic, and contains a number of genera. Some of the S. are parasitic in man, some in mammals, birds, reptiles, &c.

STRO′NGYLUS (from the similar Greek word signifying *round*) is the term applied to a genus of the family *Strongylidæ* (q. v.) of nematode parasitic worms. The only true S. infesting man is the *S. bronchialis* of Cobbold, previously known as *Filaria hominis bronchialis*, *Hamularia compressa*, &c. The male usually measures rather more than half an inch, while the female is upwards of an inch in length. For the general and specific characters of this rare entozoon, the reader is referred to Cobbold's *Entozoa*, p. 357. The worm was originally discovered by Treutter in 1790, who found severa

individuals in the bronchial glands of an emaciated subject. In 1845 it was again found by Dr Fortsitz at Klausenberg in Transylvania, in the lungs of a boy six years old. These are the only two cases recorded by Küchenmeister and Cobbold of its occurring in the human subject; but closely-allied species, *S. paradoxus* and *S. micrurus*, are occasionally found, according to Cobbold, in the lungs and air-passages of the pig and the calf respectively, and Küchenmeister states that he has found a species in the lungs of the sheep.

Closely allied to S. is the genus *Eustrongylus* of Diesing and Cobbold, which contains the species *E. gigas*, more commonly known as the *Strongylus gigas* of Rudolphe, Cuvier, and others. This is the largest nematode worm at present known to infest man or any other animal; 'the male measuring from ten inches to a foot in length, and ¼th of an inch in breadth; whilst the female is said to attain a length of over three feet, its transverse diameter being fully half an inch; body cylindrical, and more or less tinged with redness; head obtuse, and furnished with a simple oval aperture surrounded by six chitinous nodules: mode of reproduction, probably viviparous; eggs broadly oval, measuring about $\frac{1}{300}''$ from pole to pole.'—*Op. cit.*, p. 358. This worm occurs, according to Bremser, in the kidneys and bladder, sometimes in the abdominal cavity and the omentum, more rarely in the lungs and liver of 'martens, dogs, wolves, seals, otters, oxen, and horses.' Fortunately, it is very rare in man, and, according to Cobbold, weasels are the animals in which it is most commonly found. The accompanying figure shews one of these worms coiled up



Strongylus gigas.—From Cobbold's *Entozoa*.

within the pelvic cavity of the kidney of the coati, a species of monkey. The symptoms to which it must give rise must be much the same as those arising from abscess and degeneration of one of the kidneys, or from renal calculi. The diagnosis in a suspected case could only be established by the detection of the eggs or embryos in the urine

STRO'NSAY, one of the Orkney Islands, lies 15 miles north-east from the town of Kirkwall. It is 7½ miles long, and 6 miles in extreme breadth. Pop. about 1500.

STRONTIA. See STRONTIUM.

STRO'NTIUM (symb. Sr, equiv. 87.5, sp. gr. 2·54) is a ductile and malleable metal somewhat harder than lead, and of a pale yellow colour. When heated in the air, it burns with a crimson flame, and becomes converted into its oxide, strontia. It is unaffected by the action of dry air, but it decomposes water at an ordinary temperature, hydrogen being explosively developed; and it burns in chlorine gas, and in the vapour of iodine, bromine, and sulphur. It dissolves in dilute nitric acid, but the strong acid has scarcely any effect on it. This metal does not occur in the native state, but exists as a carbonate in the mineral *Strontianite* (so called from its being first found near Strontian, in Argyleshire), and as a sulphate in the mineral known as *Celestine* (so called from its delicate blue tint). It is obtained by the voltaic decomposition of the chloride of strontium. This metal bears to barium the same close relation that sodium bears to potassium; and the compounds of S. resemble those of barium not only in their composition but in their properties.

The oxide of S., commonly known as STRONTIA, is obtained in the same way, and resembles in almost all respects the corresponding oxide of barium, except that it is inert when taken into the system, while baryta is poisonous. When a small quantity of water is poured upon it, it slakes, giving out heat.

The salts of strontia resemble those of baryta in their general characters, and in their being precipitated from their solutions by sulphuric acid and the soluble sulphates; but they differ from them in not being thrown down by silico-fluoric acid or hyposulphite of soda, and in their communicating to the flame of the spirit-lamp and to burning substances generally, a brilliant purple-red colour. The salts of strontia occur only in the mineral kingdom, and are never found as normal ingredients of organic bodies. *Carbonate of Strontium* (Sr_2CO_3) occurs native both in a massive and crystalline form, and may be obtained artificially as a white powder by precipitating a soluble salt of S. with carbonate of sodium. *Sulphate of Strontium* occurs native in *Celestine*, a mineral which is found in beautiful rhombic prisms in Sicily. *Nitrate of Strontium* (Sr,NO_3) separates from a hot concentrated solution in large colourless transparent anhydrous octahedral crystals, which dissolve freely in water. By the addition of nitric acid, it is precipitated from its aqueous solution. This salt is insoluble in alcohol; but when finely powdered, and mixed with it, it communicates to the alcoholic flame a beautiful red or crimson colour. In consequence of this property, it is employed by the makers of fireworks. A mixture of 40 parts of nitrate of strontium with 10 of chlorate of potash, 13 of sulphur, and 4 of sulphide of antimony, deflagrates with a magnificent red colour, and constitutes what is popularly known as *Red Bengal Fire;* but the mixture is dangerous both to prepare and to preserve, having more than once been the occasion of frightful accidents to the manufacturers from its becoming ignited spontaneously.

The most important of the haloid salts of S. is the *Chloride* ($SrCl$), which may be obtained in crystals containing six equivalents of water. The water is expelled at a moderate heat, leaving the chloride anhydrous. The chloride is the only salt from which the metal has hitherto been obtained.

Regarding the history of this metal, it may be observed that strontia was discovered as an independent substances almost simultaneously by Hope and Klaproth in 1793. In 1807, Davy obtained barium and strontium from their oxides, but not in a pure state; and it was not till 1855 that Bunsen and Matthiessen succeeded in procuring perfectly pure specimens of the metal.

STRO'PHULUS. See RED GUM.

STROUD, a parliamentary borough and market-town of Gloucestershire, nine miles south-south-east of the city of Gloucester, stands in a beautiful and extensive valley, at the confluence of the Frome and Slade, which unite to form the Stroudwater or Frome. It is the centre of the woollen manufactures of Gloucestershire, and contains a number of woollen and silk mills. The water of the Frome is peculiarly adapted for use in dyeing scarlet and other grain colours; and on this account, cloth-factories and dyeworks have been built along its banks for the distance of 20 miles. The borough of S. forms part of the great west of England cloth districts. Pop. of parliamentary borough, which sends two members to the House of Commons (1871), 38,602; (1881) 40,573.

STRUENSEE, Johann Friedrich, Count of, a man who, in last century, attracted the attention and excited the sympathy of the whole of Europe, by his elevation and downfall at the Danish court. S. was born 5th August 1737, at Halle on the Salle, where his father, Adam Struensee, the author of the old Halle Hymn-book, was pastor of the Ulrichskirche. Young S. studied medicine, and when scarcely 19 years old passed as Doctor. Early alienated from positive Christianity, he zealously embraced the philosophy which had then arisen in France, and became a disciple of Helvetius and Voltaire. When his father removed to Altona, he accompanied him, and was soon afterwards appointed travelling physician to the young king, Christian VII. of Denmark; and on their return from a tour, physician in ordinary. At first, the young queen, Caroline Matilda, sister of George III. of England, looked upon him with mistrust; and it was not till 1770, when S. successfully managed the inoculation of the two-year old crown-prince, afterwards King Frederick VI., that she came round to him, intrusted him with the education of the prince, and by degrees made him the confidant of her unhappy position. S. removed the estrangement between the royal pair, which was the work of the favourite Holck, and, in consequence, rose still higher in favour with both. He was appointed Reader to the king, and Private Secretary to the queen. Since the revolution of 1660, Denmark had been under the domination of the nobility, who, as a council of state, governed the country. S. saw the disadvantages of this government of the nobles, and formed the ambitious resolve to come forward in this land of his adoption as an enlightened reformer after the model of Frederick II. To begin with, he effected the downfall of the favourite Holck, in whose stead his friend Brandt was appointed Royal Companion and Director of the Court Amusements. In order to gain the love of the people, S. proclaimed the freedom of the press. The council was dissolved, and a proclamation issued to the effect that the royal power in all its purity, as it had been handed down from olden times, was to be re-established. These measures amounted in reality to a revolution, and to a declaration of war against the aristocracy. The queen and S., in whose hands the whole power now was, chose new ministers, and excluded the feeble Christian entirely from the management of affairs. In July 1771, S. received the title of Cabinet Minister, along with unlimited power. He brought several men from Germany, whom he appointed to different offices. This introduction of strangers caused great dissatisfaction among the people. In opposition to the politics of his predecessors, S. endeavoured to free Denmark from Russian influence, and to find a natural ally in Sweden. The changes which he undertook in the internal affairs were directed to the advancement of the prosperity of the country, of civil liberty, and enlightenment. He put the finances in order, reduced the expenditure, loosened the fetters in which industry and trade had been bound, encouraged education, mitigated the penal laws, and brought order into the administration. An act passed in 1771, to a certain extent abolished serfage. All these reforms, which are in operation in the Danish dominions at the present day, were excellent; but the haste and want of statesmanlike skill with which they were carried out, made them appear as the acts of the most vexatious tyranny. S. committed a great mistake, too, in recklessly obtruding his philosophy of enlightenment in the face of the strict orthodox clergy and the pious prejudices of the people.

S. had scarcely been in power a year when the symptoms of reaction appeared in all quarters. The queen gave birth to a daughter in 1771, which, in the condition of the king, gave rise to most scandalous reports. The British ambassador, Lord Keith, who saw the catastrophe approaching, proposed to S., by the advice of George III., to take refuge in England; but S. declined doing so. At the head of the hostile party was Christian VII.'s stepmother, Juliana Maria, Princess of Braunschweig-Wolfenbüttel, who was impatient of the domination of the queen and Struensee. A bold stroke was to precipitate S. and ruin the queen, and the night when a court-ball was to take place was fixed upon for carrying out the plot. The conspirators assembled at the king's stepmother's, and by a secret door entered the bedroom of the king, and obliged him to make out 15 warrants of arrest, among others for Struensee. Christian was prevailed upon, but with much difficulty, to write out orders to arrest and convey his consort the queen to Kronenburg. S. and the queen were then taken prisoners, and the former was treated with extreme harshness, put in chains, and brought to the citadel. He was accused of an assault on the person of the king; of the intention to compel Christian to abdicate the throne; of criminal intercourse with the queen; of using a fatal system in the education of the crown-prince; and of the usurpation and abuse of supreme power. Not one of these points could be legally proved. In a second examination, however, S., with tears, confessed to having had improper intercourse with the queen; but some of his contemporaries affirm that he made the confession under threat of torture. On this important confession, a second commission was sent to the queen at Kronenburg, from whom, however, not the slightest confession of guilt could be extorted. When one of the commissioners at last remarked that if she made S. guilty of falsehood, he would be put to a disgraceful death for slandering majesty, the queen seized a pen, and began to sign a paper which contained the confession of her guilt. She had not finished when she sunk in a swoon in her chair; and it is said that some one put the pen in her hand, and guiding it, finished the name, 'Caroline Matilda.' S. was found guilty of a great and capital crime, and was sentenced to a cruel death. It was wished by some to proceed further against the queen; but the commissioners were satisfied with the simple separation of the royal pair, especially as the British ambassador threatened the appearance of a British fleet. After the king had confirmed the sentence, not without being urged by the Russian ambassador, it was carried into execution on the 28th April 1772, amid the rejoicings of the multitude. In the prospect of death, S. is said to have returned to the Christian faith. There is no doubt that he did not deserve his fate, but that he fell a sacrifice to the party of the nobles. The execution of his friend Brandt, which took place at the

same time, was a still clearer case of legal murder, as he never took any part in the affairs of government. S.'s brother would have shared the same fate, had not Frederick II. claimed him in a menacing manner as a Prussian subject. Queen Caroline Matilda left Denmark in May 1772, and died of grief in 1775, in the castle of Celle in Hanover.

In recent times, S.'s history has been recalled to memory in a tragedy by Mich. Beer and Heinr. Laube. See Höst, *Count Struensee and his Ministry* (1824; Germ. Copenh. 1826); Falkenkeöld, *Mémoires* (Paris, 1826).

STRUTS, straining pieces of timber in a roof, used to strengthen the principal Trusses (q. v.).

STRUVE, Friedrich-Georg-Wilhelm, a celebrated astronomer, was born at Altona, April 15, 1793, educated at the university of Dorpat (Russia), and appointed to a post in the observatory of that place in 1813. He became Director of the Dorpat Observatory in 1817, and continued with the utmost assiduity his observations and researches respecting double and multiple stars, adding immensely to our knowledge of these systems, and earning for himself the reputation of being one of the most skilful of practical astronomers. The instrument with which he observed was a Fraunhofer's (q. v.) refractor, of 10 inches aperture, and 13½ feet focal length; and with this telescope, in gleaning from the depths of space the materials for his three important works on double stars (1822 and 1828, 1837 and 1840, 1852), he examined no fewer than 120,000 of these twinkling luminaries. His investigations have led him to the conclusion, that the number of true double stars is much larger than was previously supposed (see Stars). S. also executed a number of important geodetic operations, such as the triangulation of Livonia, in 1816—1819, and the measurement of an arc of the meridian in the Baltic Provinces, in 1822—1827; which was subsequently (1828—1856) extended by him, in conjunction with Hansteen (q. v.) and Selander, to the North Cape; and by General Tenner southwards to Ismail in Turkey. This latter undertaking, the most extensive trigonometrical operation ever performed, when completed, gave the length of a meridian arc of 20°, and enabled geometers to determine with increased accuracy the exact form of the earth. Meanwhile, S. had been appointed, in 1839, director of the best organised observatory in the world, that of Pulkova (q. v.), and also chosen *correspondant* in the astronomical section of the Academy of Sciences of Paris. He died at St Petersburg, 23d November 1864.—His son, Otto-Wilhelm Struve, also an eminent astronomer, was born at Dorpat, May 7, 1819, was educated under his father's direction, became his chief assistant at Pulkova, and the Director of the observatory after his death. He has made numerous astronomical discoveries, among which are more than 500 new double stars, and (1847) a satellite of Uranus, and has written numerous important papers, the most noticeable of which set forth his researches on the inner or dusky ring and on the variation in breadth of the bright rings of Saturn, and on the periodic motions of double stars.

STRY'CHNIA, or STRY'CHNINE. See Nux Vomica.

STRY'CHNOS, a genus of trees of the natural order *Loganiaceæ*, having a five-lobed calyx, a tubular funnel-shaped or salver-shaped corolla, with a five-partite limb, five stamens, a filiform style, numerous ovules, and a one-celled berry, with a leathery rind, many-seeded, or, by abortion, one-seeded, the seeds discoidal and compressed. To this genus belongs the *S. nux vomica*, a tree of middling size, with ovate stalked leaves, a native of India, the fruit of which is produced in great abundance, and is about the size of a small orange; the seeds are the *Nux Vomica* of commerce, and yield *Strychnine.* The bark partakes of the poisonous quality of the seeds. The wood of the tree is very hard and durable. The Clearing-nut (q. v.) and St Ignatius' (q. v.) Bean are produced by species of this genus, to which also belongs the tree (*S. toxifera*) which produces the Woorali or Curare (q. v.) poison of South America. Another species is the Upas Tieuté (*S. Tieute*) of Java, a large climbing shrub, the bark of which is extremely poisonous, containing a very large quantity of strychnine. The wood of a species found in the north of India (*S. colubrina*), which is also a climber, is an imaginary cure for snake-bites. The bark of *S. pseudo-quina*, a Brazilian species, is used as a substitute for cinchona.

STRYPE, Rev. John, a voluminous ecclesiastical historian, was born in London in 1643. He studied at Cambridge, entered the church, and held for many years, with other smaller livings, the rectory of Low Leyton, in Essex. He died at Hackney in 1737, having reached the great age of 94. His works fill thirteen large folio volumes. The most important are—*Memorials of Archbishop Cranmer* (1694); *Life of Sir Thomas Smith, Secretary of State to Edward VI. and Elizabeth* (1698); Lives of *Bishop Aylmer* (1701), *Sir John Cheke* (1705), *Archbishop Grindal* (1710), *Archbishop Parker* (1711), and *Archbishop Whitgift* (1718); *Annals of the Reformation* (vol. i. 1709, vol. ii. 1723, vol. iii. 1728, and vol. iv. 1731); *Ecclesiastical Memorials*, relating to religion and the Church of England under Henry VIII., Edward VI., and Queen Mary, in 3 vols. folio, published in 1721. This is his best work, forming, with Burnet's more readable *History of the Reformation*, a consecutive and full account of the reformed Anglican Church. S. also published an enlarged edition of Stow's *Survey of London*, with several sermons and pamphlets. As a writer, he is heavy, but honest and plodding, and he was a faithful transcriber of the ancient papers he published, which, he says, were all copied with his own hand.

STUART, Charles Edward Lewis Casimir, often called the younger Pretender, the eldest son of James Francis Edward, Prince of Wales, known as the elder Pretender, or Chevalier St George (see Stewart, Family of), and his wife Clementina Sobieski, grand-daughter of the celebrated Polish monarch, John Sobieski. He was born at Rome, on the 31st December 1720, and bore among the Jacobites the title of Prince of Wales. He served under Don Carlos in Spain, and in his youth is described as having been handsome, affable, and engaging in manners. In 1743, 28 years after his father's unsuccessful attempt to regain the crown, a scheme was contrived in France, with the support of the Jacobites in England, by which Charles Edward was to recover the throne of Great Britain for his family. The first contrived project was to land an army in Kent, where were many adherents of the exiled House; and troops to the number of 15,000 were assembled, and transports provided at Boulogne, Dunkirk, and Calais to carry them to England. But the squadron which was to have convoyed the transports fled before the British fleet under Sir John Norris; a storm destroyed the transports, and most of the troops were drowned. Charles, however, only awaited a favourable opportunity to make a fresh attempt. In July 1745, when George II. was in Hanover, and Scotland almost without military, he sailed from Nantes, in company with the Marquis of Tullibardine, and

a few other devoted followers, and landed in the bay of Lochnanuagh, whence he proceeded to Kinlochmoidart, where the Highland clans attached to his cause were summoned to rise. Ten days later, Charles's standard was set up at Glenfinnan; and he marched southwards at the head of a large body of hardy mountaineers. Government offered a reward of £30,000 for the apprehension of the Pretender's son, who retaliated by offering a like reward for the apprehension of the Elector of Hanover. At Perth, the insurgents were joined by the Duke of Perth and Lord Strathallan, with a numerous retinue of followers; and on their approach, Edinburgh surrendered without resistance, the castle, which was in possession of the king's troops, still holding out. Charles took up his residence at Holyrood Palace, where he proclaimed his father king of Great Britain, and himself regent.

Meanwhile, Sir John Cope, the commander-in-chief of the king's troops in Scotland, having collected some reinforcements in the north, came from Aberdeen to Dunbar by sea, and encamped at Prestonpans. He was there unexpectedly attacked by the Highlanders, and ignominiously routed, leaving baggage, cannon, and camp equipage on the field. Contrary to the advice of his council, Charles, who could not bear opposition, resolved to advance into England, though his force hardly exceeded 6500 men. Carlisle surrendered at his approach, and he proceeded unmolested as far as Derby. In the meantime, three English armies, each larger than his own, were preparing to meet him. Being unable to raise any recruits in England, he found it necessary to retreat into Scotland, where he hoped to meet a reinforcement under Lord John Drummond. On their way north, the Highlanders were pursued by the Duke of Cumberland, whom they defeated near Penrith. Finding that Edinburgh was now in possession of the king's troops, Charles, joined by Lord John Drummond and Lord Strathallan, made his way to Stirling. That town surrendered to him, and he laid siege to the castle. General Hawley, in endeavouring to raise the siege, was utterly routed by Lord George Murray, at the head of the Macdonalds of Keppoch. But the advance of the Duke of Cumberland obliged the rebels to retreat further north, and for a time they carried on a desultory war with the king's troops in the neighbourhood of Inverness. On 16th April 1746, the Duke of Cumberland encountered Charles's army on Culloden Moor, and opened a heavy cannonade on them. The Highlanders at first rushed boldly forwards; but on the advance of the royal infantry, they gave way; the battle soon became a rout, and the fugitives were pursued and slaughtered by the dragoons, who gave no quarter, and spread carnage and desolation over the country. The rebels lost that day at least 1000 men of the bravest and most devoted to the cause. Charles escaped to the Hebrides, hunted by the king's troops; disguised in female attire, he was conveyed to Skye in an open boat by Flora Macdonald, daughter of Macdonald of Milton. For months he wandered in concealment among the mountains of Skye and the mainland, where he had many hairbreadth escapes; and though his secret was known to hundreds of the poorest of the people, no one was tempted by the £30,000 reward to betray him. He eventually escaped to France, and no further attempts were made to reinstate the exiled family.

Charles Edward remained in France till the peace of Aix-la-Chapelle (1748). It was made a condition of that treaty that France should abandon the cause of the Stuarts; and Charles, refusing to quit France voluntarily, was conducted with a guard out of the kingdom, and retired to Rome.

He married, on 17th April 1772, Louisa Maximiliana de Stolberg-Guedern, daughter of Gustavus Adolphus, Prince of Stolberg-Guedern. The union did not prove a happy one, and the princess withdrew herself from him. See ALBANY, COUNTESS OF. In the latter years of his life, the prince was addicted to intoxication. When his claims ceased to be supported by any foreign power, he dropped the title of Prince of Wales, and assumed that of Count of Albany. He died at Rome, 31st January 1788, and was buried at Frascati. There was no issue of his marriage, but he left a natural daughter, on whom he bestowed the title of Duchess of Albany, and to whom he bequeathed considerable property.

Two brothers, generally known as John Sobieski Stuart and Charles Edward Stuart, endeavoured, some years ago, to persuade the world that they were legitimate grandsons of Charles Edward. In point of fact, they were sons of Captain Thomas Allen, R.N., and grandsons of Admiral John Carter Allen, who died in 1800. Their story, as set forth, with some slight mystifications, in a work called *Tales of the Century, or Sketches of the Romance of History between the years* 1746 *and* 1846, was to the effect that their father, in place of being Admiral Allen's son, was a son of Prince Charles and the Princess Louisa, whose birth was kept secret, from fear of the Hanoverian family, and who was intrusted to Admiral Allen, and passed off by him for his own son. This story was conclusively refuted in the *Quarterly Review* for June 1847.

STUART, GILBERT CHARLES, American painter, was born at Narraganset, Rhode Island, in 1756. In his boyhood, he accompanied a Scotch painter named Alexander to Edinburgh, with whom he studied his art; but his master dying, he worked his passage home, and began to paint portraits at Newport. In 1778, he made his way to London, where he led for two years a wild Bohemian life; but his talent was recognised by his countryman, Benjamin West, President of the Royal Academy, who took him into his family, and whose full-length portrait he painted for the National Gallery. In 1781, he opened his studio in London, and painted the portraits of his Majesty George III., H.R.H. the Prince of Wales, the Duke of Northumberland, Sir Joshua Reynolds, John Kemble, Colonel Barré, and many other celebrated characters. He also made a professional visit to Dublin, and in Paris painted a portrait of Louis XVI. In 1793, in the fulness of his powers and fame, he returned to America, and painted portraits of Washington, Jefferson, and many of the distinguished men of the period, and commenced a portrait of John Quincy Adams, which at his death was finished by Sully. He died at Boston, July 1828.

STUART, MOSES, American divine and author, was born at Wilton, Connecticut, March 26, 1780, and educated at Yale, where he remained for some time as a tutor. He began the study of law, but abandoned it for theology, was ordained as pastor of a Congregational church at New Haven in 1806; and in 1809, was appointed Professor of Sacred Literature at the Theological School at Andover a position he filled till 1848. During this period, in addition to his professorial duties, he wrote a *Grammar of the Hebrew Language*, without points; *Letters to the Rev. W. E. Channing; Hebrew Grammar*, with points (based on Gesenius); *Commentaries on the Epistle to the Hebrews*, and *the Epistle to the Romans;* on the Books of Ecclesiastes, *Proverbs*, *Daniel*, and the *Apocalypse; Hebrew Chrestomathy; Essay on the Liquor Traffic; Essay on Christian Baptism; Hints on the Prophecies; Conscience and the Constitution*—manifesting in all acuteness, vigour,

and versatility. He died at Andover, Massachusetts, January 4, 1852.

STU'CCO, a composition used for the finer parts of plaster-work, such as cornices, enrichments, &c. Gypsum (q. v.), or Plaster of Paris, is used for this purpose. A coarser kind of stucco is also used for making floors, and for plastering the exterior of buildings.

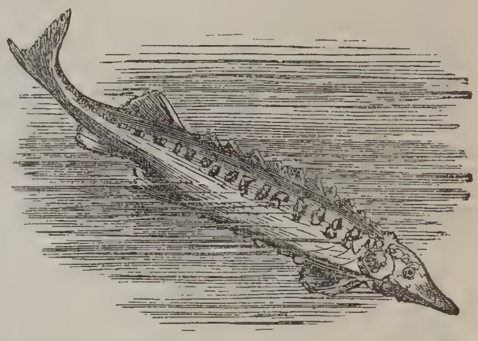
STUFFING, in Cookery, means force-meat used for filling the bodies of small animals, such as poultry, or for stuffing openings made for the purpose in large joints. It usually consists of bread-crumbs. savory herbs and other seasonings, minced very fine, and made into a paste.

STUHLWEI'SSENBURG (Hung. *Székes Fejérvár*, Slav. *Bielihrad* or *Bialigrad*, Lat. *Alba Regalis* or *Alba Regia*), a royal free town of Hungary, and seat of a bishop, lies in a swampy plain in the neighbourhood of the marshes of Sár-Rét, 16 miles north-east of Lake Balaton. The principal buildings are the splendid cathedral of the Virgin Mary, the church of St John, and the bishop's palace. It has several Catholic schools, a military academy, and a theatre. The inhabitants manufacture cotton cloths, flannels, leather, silk, and knives ('Stuhlweissenburg clasp-knives'), and extract soda from the swamps, which are, moreover, rich in fish, crabs, tortoises, and water-fowl. Pop. 19,000. S. is built on the site of the Roman *Floriana*, and from 1027 to 1527, was the place where the kings of Hungary were crowned and buried, 14 of whom repose here. In later times, it suffered much from the ravages of war, and was for some years in the hands of the Turks.

STÛPA. See TOPE.

STURDY, or the GID, affects sheep, and occasionally cattle, and is caused by the presence within the brain of a hydatid, reaching sometimes the size of a hazel-nut, and floating in a watery fluid enclosed in a membranous sac. This hydatid, when given to dogs, is known to produce tape-worms, and conversely itself originates from the ova of the tape-worm ejected on the pastures by dogs, rabbits, or even by sheep themselves. In the state of ova, or in some of its earlier minuter transitional forms, the hydatid embryo is picked up along with the grass, passes into the blood, and is thence laid down in the soft loose textures of the brain. It is most common in low damp pastures, and amongst sheep from six to twenty months old. The animal cannot properly seek its food, loses condition, staggers when moved, turns stupidly round almost in one spot, and usually towards the side on which the hydatid lies. The parasite and its sac may generally be safely removed by placing the sheep, with its feet tied, on a table or bench, searching for the softened portion of the skull, which generally overlies the hydatid, laying back a flap of skin, and introducing the trochar and canula, and when the sac is deep-seated, cautiously withdrawing it with the help of a small syringe. Protected by a leather cap and simple water-dressings, the wound speedily heals.

STU'RGEON (*Accipenser*), a Linnæan genus of cartilaginous fishes, now forming the family *Sturionidæ*, belonging to the *Chondrostean* division of the true fishes, or *Actinopteri*, being the nearest of that subclass to the *Crossopterygia*. The gills are free, as in the osseous fishes. The vertebral column is soft; and there are no evident sutures in the skull. Reproduction is by roe, as in osseous fishes. The form of sturgeons is elongated and angular; the plates are arranged in regular rows; the head is cuirassed; the snout long and conical; the mouth is on the under surface of the head, tubular, protractile, and without teeth. The upper lobe of the tail is much larger than the under. The dorsal and anal fins are opposite to one another, behind the ventrals. The air-bladder is very large, and communicates with the gullet by a large hole. The species of S. are numerous, and inhabit both the sea and fresh-water, ascending deep muddy rivers at certain seasons, and temporarily inhabiting lakes. Numerous species are found in the northern parts of the world, although there are none in the Arctic Ocean, or the rivers which flow into it, but the south of Siberia and North America particularly abound in them. They are plentiful in the Caspian and Black Seas, and in the rivers connected with them, where the S. fishery is of great importance, supplying the inhabitants of large districts with their chief article of subsistence, and producing great quantities of Caviare (q. v.), or preserved S. roe, and of isinglass (see GELATINE), for sale. The COMMON S. (*A. sturio*) is sometimes caught in the



Sturgeon (*Accipenser sturio*).

mouths of British rivers, most frequently in salmon-nets; and is a large fish, six or eight feet in length, with five rows of flattened plates; the muzzle long and pointed. Another species (*A. latirostris*), with broader muzzle, also visits the British coasts, but they are not popularly distinguished. The S. is more abundant on the northern coasts of Europe. It is also found in the more southern parts, and was in very high repute for the table among the Greeks and Romans. At their banquets, it was introduced with particular ceremonies. In England, when caught in the Thames, within the jurisdiction of the Lord Mayor of London, it is a *royal* fish, reserved for the sovereign. Its flesh is white, delicate, and firm. It is used both fresh, generally stewed, and pickled or salted.—The largest species of S. is the BIELAGA, or HUSO (*A. huso*), of the Black and Caspian Seas, and their rivers. It attains the length of 20 or 25 feet, and has been known to weigh nearly 3000 lbs. It enters the rivers in winter, while they are still covered with ice. Great part of the caviare of commerce is made from it, and much isinglass, which is merely the air-bladder washed, cut into strips, and dried. The STERLET (*A. Ruthenus*) is a comparatively small species, only about three feet in length, found in the same regions, and particularly esteemed for the delicacy of its flesh, and of the caviare obtained from it. There are several other European and Asiatic species; and some of the North American rivers and lakes abound at certain seasons in species of S. which are peculiar to them.—Sturgeons spawn in fresh water, but the young are seldom seen there and are supposed to descend very early to the sea.

STUTTGART, the royal residence and metropolis of Würtemberg, is beautifully situated in a widening of the Nesenbach valley, the hills forming a semicircle of eminences clothed with vineyards, orchards, and gardens. The basin in which S. nestles is 897 feet above the sea-level, and enjoys a mild and healthy climate.

Except the very oldest part of the city, the streets are broad, and the buildings handsome. The Schloss, or palace, is a fine modern building. The royal park and gardens extend from the north-east side of the palace for two miles in the direction of Carlstatt, have an area of 560 acres, are adorned by fine groups of trees, and intersected by shady avenues, in which all classes may freely walk. The cathedral, built in the 15th c., was gifted by the king, in 1852, with several beautiful painted windows. Other principal buildings are the Royal Theatre, public library, Mint, the royal stables for 300 horses, &c. A fine statue of Schiller has been erected in the palace plain. The private royal library, in the palace, contains 54,000 printed books and 800 MSS.; the public royal library 200,000 volumes, 3600 MSS., 120,000 smaller works, and a peculiar collection of 8700 Bibles in 80 languages.

S. has many benevolent institutions and societies. There is direct railway communication with the leading cities of Germany, Switzerland, France, Belgium, and the Netherlands. Pop. in 1855, 50,804; in 1861, 61,314; in 1871, 91,623, of whom 78,624 were Protestants and 10,708 Catholics; in 1880, 117,303. Since 1866 S. has increased rapidly. Principal industries are the manufacture of cotton and half-wool fabrics, iron and tin work, gold and silver articles, chemicals, tobacco, beer-brewing, &c. S. has a high position in the book-trade, and is the place of meeting of the Booksellers' Union of Southern Germany. The annual vintage of the district is valued at 200,000 florins, and the produce of the gardens and orchards at nearly double that amount. S. was the birthplace of Hegel; here, also, Schiller's youth was spent. The name of the city occurs for the first time in 1229. It was besieged by King Rudolph of Hapsburg, 1286—1287, and appears then to have been a place of strength. Between 1634—1638, nearly 9000 people died of the plague; and during the wars of Louis XIV., S. was thrice taken; and again in 1796, 1800, and 1801.

STYE, or STY, is the popular name for a minute boil occurring at the edge of the eyelid, and known to surgeons under the term *hordeolum*. It begins as a small, red, tense swelling, accompanied with considerable itching, and a feeling of stiffness. As the inflammation goes on, the lid may become so swollen as to keep the eye closed. In a few days, matter forms, a white point appears at the apex of the swelling; and when the cuticle gives way, pus and a small slough of connective tissue escape, after which there is a general remission of the symptoms, and the eyelid soon resumes its natural state.

This common affection is chiefly confined to scrofulous and delicate children, but it is sometimes observed in persons of more advanced age. The best local treatment consists in the application of warm-water dressings with lint and oiled silk; and if any hardness remains after the discharge of the matter, dilute nitrate of mercury ointment may be applied. The stye should never be rubbed (notwithstanding the common prejudice in favour of rubbing it with a gold ring), nor, in general, is it necessary to puncture it. To prevent the recurrence of these little boils, attention should be paid to the diet, which should be abundant and nourishing, to the state of the bowels, and to the general health, and tonics may usually be prescribed with advantage. The old form of the word was *stian*.—See Holland's *Plinie*, book xxviii. ch. xi.

STYLE, Old and New. See Calendar.

STYLI'TÉS. See Pillar Saints.

STY'LOBATE, the substructure of a temple beneath the columns. It is sometimes continuous all round the peristyle in the form of three high steps; sometimes it resembles a continuous pedestal along each side, with flights of steps at either end.

STY'PTICS (Gr. *styptikos*, astringent) are agents employed in Surgery for the purpose of checking the flow of blood by application to the bleeding orifice or surface. See Bleeding.

STY'RIA (Ger. *Steiermark*), a Cis-leithan province of the Austro-Hungarian monarchy, is bounded on the N. by Upper and Lower Austria, E. by Hungary and Croatia, S. and W. by Carniola, Carinthia, and Salzburg. Its area is 8671 English sq. m., and pop. (1880) 1,212,367, who are partly of German and partly of Slavic origin. S. is a mountainous country, being traversed in the west and centre by branches of the Noric Alps, which spread out into numerous ramifications; while the southern portion, between the Drave and the Save, is occupied by branches of the Carnic Alps. The climate of S., like that of most mountainous countries, is variable, but is generally raw and cold in the northern and more mountainous portion, and mild in the south. But in spite of its physical character, agriculture is so zealously prosecuted, that ⅘ths of the country are under cultivation, producing rye, wheat, oats, and maize. Vines are largely cultivated in various parts, and orchards are numerous. The chief wealth of the country, however, lies in its mineral products, which include, besides immense quantities of iron, lead, copper, gold, silver, marble, limestone, and slate, with abundance of salt and coal. The chief industries are thus necessarily in connection with the production of iron and steel, and their manufacture into articles of such excellent quality as to be in great demand in other countries. There are also manufactures of brass and lead articles, earthenware, paper, tobacco, glass, white-lead, copper hammers, and of cotton, linen, cloth, &c. S. was anciently divided between Noricum and Pannonia, and has generally followed the fortunes of the two provinces of Upper and Lower Austria.

STYX (Gr. *stug-*, to hate, abhor), a waterfall in Greece, near the town of Nonacris, in the north-east of Arcadia, descends perpendicularly over lofty and precipitous rocks, and forms a small torrent, which falls into the Crathis. The scenery around it is weird and desolate, so that the Greeks regarded the S. with superstitious awe, the water being supposed to be poisonous, and to break every vessel into which it was put, except those made of the hoof of a horse or an ass. It was reported that Alexander the Great had been poisoned by it. It is now called *ta Mauraneria* (the Black Waters), and also *ta Drakoneria* (the Terrible Waters), the belief in its poisonous qualities still surviving.—In Mythology, the S. was a river of Hades, round which it flowed seven times, and over which Charon (q. v.) conveyed the shades of the departed. As a goddess, S. was the daughter of Oceanus and Tethys, dwelling in a grotto at the entrance of Hades. She was the confirmer of the most solemn oaths of the gods.

SUA'BIA (Ger. *Schwaben*), **SWABIA, or SUEVIA**, an ancient duchy, in the south-west of Germany, so named from a horde of Suevi, who spread over it in the 5th c., and amalgamated with the Alemanni, its previous inhabitants. It existed as a great

duchy of the Frank Empire till the 8th c., when Alsace and Rhætia were separated from it, and the remainder, retaining its name of S., was thenceforth governed by *nuntii cameræ*, or royal delegates, one of whom having in 915 usurped the title of Duke of Alemannia, was condemned by the German Diet, and decapitated in 917. S. at this time was bounded on the W. and S. by the Rhine, on the E. by the Lech (which separated it from Bavaria) and Franconia, N. by the palatinate of the Rhine and Franconia; and contained about 13,000 English square miles. In 918, however, S. was acknowledged as a ducal fief of the Empire; and after changing hands several times, was (1080) bestowed upon Count Frederick of Hohenstaufen (q. v.), the founder of the illustrious House of this name, also known as the House of Suabia. Under the rule of this prince and his successors, S. became the most rich, civilised, and powerful country of Germany, and the ducal court was the resort of the Minnesingers (q. v.); but the wars of the Guelphs and Ghibellines, and the quarrel with the French respecting Naples, put an end to the dynasty in 1268. The ducal vassals in S. rendered themselves almost independent, and professed to acknowledge no lord but the emperor. During these dissensions arose the lordships of Würtemberg and Baden, with numerous lesser states, holding direct of the crown, and opposed to them the cities, which strove also for an equal independence, and at last, in reward of important service, obtained in 1347 great additional privileges. A number of them united to make common cause against the neighbouring feudal lords in 1376 (known as the *First Suabian League*); an opposite league was formed between Würtemberg, Baden, and 17 towns in 1405, called the League of Marbach; and both took part in the war of Swiss independence, the former in support of the Swiss, the latter of the Austrians. At last, the towns, which had been rapidly increasing in wealth and power, decided at Ulm, in 1449, to form a standing army, and a permanent military commission, for the forcible preservation, if necessary, of peace and order; and the Count of Würtemberg, the most powerful of the opposite party, having joined them, was appointed military chief of the league, which ultimately grew up into the *Great Suabian League*, and exercised both administrative and judicial authority over the whole country, effectively repressing feudal quarrels. In 1512, S. became one of the ten circles into which Germany was now divided, received its complete organisation in 1563, and retained it almost without change till the dissolution of the Empire in 1806. But during this period, the wars of the towns with Würtemberg, the Peasants' War, of which S. was one of the foci, the Thirty Years' War, and those between France and the Empire, destroyed the democratic constitution of the towns, and with it their energy, and then their prosperity disappeared, leaving now no relic which could suggest their former great political importance.

SUA'KIN, a seaport belonging to Turkey, on a small rocky island in the Red Sea, off the west coast of Africa, but near the shore, in lat. about 19° 10′ N. It has a good harbour, and a considerable trade, especially in gums; and it is a station for pilgrims passing to and from Africa. Pop. estimated at 8000.

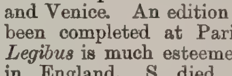
SUARES, FRANCISCO, the most celebrated of the modern scholastic and polemical divines of the Roman Catholic Church, was born at Granada in 1548. His early studies were singularly unpromising; and it is remarkable, in the history of a man afterwards so eminent, that it was not without great difficulty, and after repeated trials, that he obtained admission into the Society of the Jesuits. His later career, however, was brilliant, quite in proportion to the dulness of his first beginnings; and he taught philosophy and theology with remarkable success, first at Alcala, and afterwards at Salamanca, Rome, and Coimbra. The accounts given of his habits of application to study are almost beyond belief. He is said to have habitually devoted seventeen hours a day to study. Of his power of memory, the marvels related are scarcely less prodigious. He is said to have been able to repeat at will any portion of the whole 23 folio volumes of his own works, even to the quotations from the Fathers and other theological writers with which they abound. S. may truly be described as the ablest and greatest of the modern scholastics; but in his works scholasticism appears in its best form; for although they abound in discussions uninteresting, and indeed unintelligible, to persons unacquainted with scholastic terminology, yet they may also be truly said on each subject to exhaust the whole of the learning, ancient and modern, which existed relating to that subject at the date of their publication. On the philosophy of the ancients S. is especially copious and accurate; and of most of the modern German philosophy we may find the germ in the pages which he devotes to the account of the opinions of the ancients.

In the scholastic controversies on Grace and Free Will, S. was strongly opposed to the Thomistic doctrine; but he also rejected the opposite system of Molina. See MOLINISM. The scheme of reconciling the freedom of the will with the efficacy of grace, and of saving at the same time the doctrine of 'special election,' devised by S., is called *Congruism*, and is explained under the head MOLINA. The works of S. are entirely theological, or ascetic, and were printed in 23 vols. folio at Lyon, Mainz, and Venice. An edition in 28 vols. 4to has recently been completed at Paris, 1861. His treatise *De Legibus* is much esteemed, and has been reprinted in England. S. died at Lisbon in 1617.—See Des Champs, *Vie de Suares* (4to, Perpignan, 1671).

SÛ'BAHDÂR was, under the Mogul government, the title of a governor of a province. It now designates a native officer, holding a rank equivalent to that of captain under the European officers.

SUBA'LTERN, in the Army, or rather in a regiment, is a company officer below the rank of captain; i. e., a lieutenant, ensign, or cornet.

SUBDO'MINANT, in Music, the fifth below the tonic; the note whose dominant is the tonic. Thus F is the subdominant of C, and C of G. One of the keys most nearly related to any key is its subdominant; and the easiest of all modulations is that from a key to its subdominant, which is effected by adding the dominant seventh to the common chord, and the resolution of this chord is the common chord of the subdominant; e. g., in modulating from the key of C to the key of its subdominant F, we have



. See DOMINANT.

SUBIA'CO, a city of the former Papal States, capital of the province of that name. Pop. 16,340. It is built upon a hill, on the right bank of the Teverone, contains a very fine cathedral dedicated to St Andrew, many monuments of antiquity, and some handsome palaces. In its neighbourhood, there are many petrified trees. The surrounding mountains abound in fine marbles. In S., the order of St Benedict was instituted; and in the 15th c., one of the earliest

printing-presses in Italy was established, the editions issued from which are greatly sought after.

SUBJECT. See OBJECT.

SUB-KINGDOMS, ANIMAL, a term which has recently begun to be used by zoologists to designate the great primary divisions of the animal kingdom, as *Vertebrata*, *Mollusca*, &c.—In like manner, *sub-families* are distinguished, as *Arvicolinæ* (*Arvicolidæ* of others) as a sub-family of *Muridæ*, and *Phœnicopterinæ* as a sub-family of *Anatidæ*. The form of the name is, however, different in different branches of natural history. The terminations *-idæ* and *-inæ* distinguish the families and sub-families in some departments of the animal kingdom. This distinction is not yet recognised in the insect tribes.—In Botany, the natural orders are generally designated by names ending in *-aceæ*, and the sub-orders or tribes by names ending in *-eæ;* but this rule is not fully adopted, except by Lindley, and those who follow his system.

SUBLAPSA'RIAN (Lat. *sub-lapsum*, after the Fall), the name given to one section of the school of divines, who maintain the doctrine of absolute decrees of Election and Reprobation. It is possible to conceive God making such a decree in two different ways, either on the hypothesis of His foresight of the fall of Adam, and thus of original sin, or, independently of such foresight on His part, and without any reference to such foresight, and entirely out of His own free will and determination. The Sublapsarian system supposes the former; and thus refers the eternal election or reprobation of men by God to His foreseeing that all men would fall in Adam, and thus would deserve eternal reprobation. Out of the entire mass of mankind thus fallen, He freely pre-elects some to life, and equally freely pre-dooms others to death. This distinction is not confined to the Calvinistic schools of divinity; it is also found among the Roman Catholic. But even the most extreme of the latter contend that in this system the liberty of man is not destroyed, inasmuch as they hold that, even on the supposition of the fall of Adam, 'sufficient grace' is offered to all men; and no one is pre-doomed to death except on the hypothesis of the prevision, on God's part, of this particular individual's having freely sinned.

SUB-LIEUTE'NANT is the junior combatant commissioned officer in the royal navy. When a midshipman has served six years, and can pass in seamanship and certain other subjects, he becomes a sub-lieutenant, and is eligible for promotion to lieutenant, on opportunity occurring. The pay of a sub-lieutenant is £91, 12*s*. 0*d*. a year, and the half-pay, £45, 12*s*. 6*d*. An officer usually serves but a short time in this ill-paid rank. Until within a few years, the sub-lieutenant was called a Mate (q. v.).

SUBLIMA'TION is a chemical process similar to distillation, but differing from it in the nature of the substances to which it is applied. While in distillation, *liquids* are converted by the agency of heat into vapour, which is condensed in the liquid form usually by the cooling action of water; in sublimation, *solid* bodies are reduced by heat to the state of vapour, which reassumes the solid form on cooling. Sublimation is usually conducted in a single vessel of glass or iron, the product being deposited in the upper part of it in a solid state, while the impure residue remains at the bottom: but in the case of sulphur, the vapour is condensed on the walls of a large chamber. Iodine affords a good example of sublimation. On gently heating the lower part of a Florence flask containing a little of this substance, a purple vapour arises, which almost immediately condenses in small brilliant dark purple crystals in the upper parts of the flask, while any impurity that may be present remains at the bottom. Amongst the substances obtained by this process, and employed in the Pharmacopœia, are arsenious acid, benzoic acid, corrosive sublimate, and sublimed sulphur.

SUBLI'ME. Objects indicating great Power, vast Expanse, or lofty Elevation, excite in the beholder a feeling of pleasurable elation; and the name 'sublime' is applied both to the objects and to the feeling.

The precise quality in things that arouses this mode of pleasurable excitement, has been variously assigned. According to Burke, *terror* is, in all cases whatsoever, either more openly or more latently the ruling principle, or, at all events, one of the chief sources of Sublimity: Blair suggested that *mighty power or force* is the cause; Payne Knight ascribed it to *mental energy;* Kaimes considers it due to *height or elevation;* Dugald Stewart, in an elaborate essay, affirms that *elevation* is the leading characteristic, and that expanse and power are sublime by suggesting or implying great height; Sir W. Hamilton says that Sublimity requires *magnitude* as its condition, and exists in three forms—Space, Time, and Power.

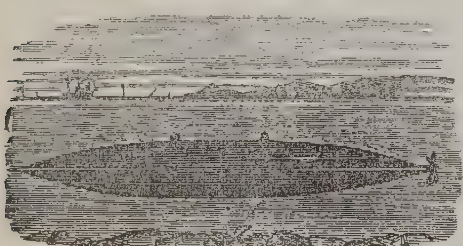
The feeling itself has also been described variously. If this could be fixed, we should have a key to the objective quality. Longinus characterised it, in reference to literary composition, as 'filling the reader with a glorying, and sense of inward greatness.' Some would call it a 'sense of security' in circumstances of terror or danger. Hamilton describes it as 'a mingled feeling of pleasure and pain —pleasure in the consciousness of the strong energy, pain in the consciousness that this energy is vain.' The connection with the sentiment of Power is generally admitted; but as the comparison of the object with self suggests our own littleness at the same time, there may be a doubt as to whether the emotion is due to the Power, to the Littleness, or to the combination of both.

Referring to the generic sentiment of Power, which is evidently at the foundation, we find that the feeling of superior might in ourselves is cheering, elating, stimulating; and that the sense of littleness or inferiority is a depressing and enfeebling state of mind, a state of pure pain, redeemable in certain circumstances by other feelings, as when our inferiority is only in the comparison with an object of love or veneration, or when it is the condition of some compensating superiority—'the courtier stoops to rise.' The presumption, therefore, is that the elation of the Sublime is connected with the notion of Power. It may be felt although the power is not actually possessed, but imagined, borrowed, or conceived, through a sort of sympathy with the *appearances* of great power or might. If this account of the Feeling be correct, Power must be a principal quality in its Objects; and if with this we combine voluminous sensation (and the corresponding ideas, vastness of expanse and greatness of time), we shall probably be able to explain the Sublime in all its forms.

SUBMARI'NE FORESTS occur at several places around the shores of Britain and Ireland. They consist of beds of impure peat, containing the stools of trees which occupy the sites on which they grew; but by change of level, the ancient forest surfaces are now covered by the tide even at low water. No kind of tree has been found in these forests which does not exist at the present day in the country, and the underwood and herbaceous plants, as far as they have been determined, agree specifically with those found now in similar

localities. Submarine forests belong to the Recent or Quaternary period, and occur above the Boulder Clay.

SUBMARINE NAVIGATION. When the Diving-bell (q. v.) had shewn that air for respiration can be supplied to persons placed in adequately arranged vessels under water, ingenious men began to speculate on the possibility of navigating closed ships or boats in similarly exceptional circumstances. Cornelius Drebell made a vessel to be rowed under water, and James I. caused it to be tried on the Thames. What was the exact nature of this invention, does not seem to be now known. Boyle said of it that it comprised an arrangement whereby 'the composition of a liquid speedily restored to the troubled air such a proportion of vital parts as would make it again for a good while fit for respiration.' Bishop Wilkins, in his *Mathematical Magic*, speculated 'concerning the possibility of framing an ark for submarine navigation;' he spoke of the wonderful advantages of such a contrivance, but, unfortunately, did not describe the contrivance itself. In 1774, an inventor named Day lost his life during an experimental descent in Plymouth Sound, in a vessel of about 50 tons burden; he intended to make it rise after a submersion of considerable duration, but failed. Mr Bushnell, of Connecticut, contrived in 1775 a submarine vessel, intended to have been used in warfare; it appears to have been propelled by some kind of Archimedean screw. Robert Fulton, while at Paris in 1796, invented a box which, when filled with combustibles, might be propelled under water, and made to explode beneath the bottom of a ship, so as to blow it up; but the attempt was a failure. He also made a submarine boat for the same purpose, which was tried on several of the French rivers with partial success; later in his life, he really blew up an old ship's hull by such means in America. Some of the suggestions for submarine navigation have depended on the ship or boat carrying store-vessels filled with oxygen, to replenish the air, the carbonic acid being absorbed either by cream of lime or a strong solution of ammonia. Attention was directed, in 1859, to a submarine boat, brought to Britain by Mr Delaney of Chicago. According to his patent,



Delaney's Submarine Boat.

the vessel was egg-shaped in transverse section, and diminished nearly to a point at each end. There was a rudder at one end of a hollow shaft; and the axis of a screw-propeller passed through the shaft. The boat was completely enclosed on all sides, except certain pipe-openings. There were two iron tanks in the interior; one had air forced into it by an air-pump; a pipe, with a stopcock, communicated with the second tank, which contained water. The engineer of the boat, by pumping water into or out of the second tank, through the action of the air in the first, could raise or lower the boat to different depths in the water. A steam-engine was to furnish the propelling power, and provision was made for purifying the respired air; but the details of operation were by no means clearly described. Torpedos and other destructive contrivances, though acting under water, yet not containing men, are not properly submarine vessels. See TORPEDOS.

SUBO'RDINARY, or SUBO'RDINATE ORDINARY, in Heraldry, a name given to a certain class of charges mostly formed of straight or curved lines. Heralds vary a little in their enumeration, but the following are generally held to come within this category: the Bordure, the Orle, the Tressure, the Flanche, the Pile, the Pall, the Quarter, the Canton, the Gyron, the Fret, the Inescutcheon, the Lozenge, the Fusil, and the Mascle. Each subordinary will be found noticed under a separate article. Some heraldic writers account the Pile an ordinary, and the diminutives of the ordinaries are sometimes ranked as subordinaries. See ORDINARIES, HONOURABLE.

SUBORNA'TION OF PERJURY is the offence of procuring another to take such a false oath as constitutes Perjury (q. v.) in that other. It is a misdemeanour, punishable anciently by death; afterwards banishment, or cutting out of the tongue; then forfeiture of goods; and latterly, as at present, by fine and imprisonment.

SUBPŒ'NA, in law practice, means the writ or process by which the attendance of a witness at a court of justice is compelled for the purpose of testifying in civil cases in the county, and in criminal cases when in the state. In civil cases, when the witness is out of the county, the testimony is procured by means of deposition. When the witness has been duly subpœnaed, and refuses to obey, the court can compel his attendance by means of a writ of attachment, and punish him for contempt of the court. A subpœna is directed to the sheriff of the county where the witness may be found, and the sheriff may by writing therein depute any disinterested person to serve and return such subpœna.

SUB RO'SA, 'under the rose'—i. e., between ourselves, or in secrecy. It was customary among the ancient Germans, on occasions of festivity, to suspend a rose from the ceiling above the table, as a symbol that whatever was said during the feast by those present would be afterwards forgotten, or at least be kept as a secret among themselves.

SU'BSIDIES, a term in Politics, used in two different senses: 1. It is applied in English political history to taxes levied not immediately on property, but on persons, in respect of their reputed estates in lands or goods; or customs imposed on any of the staple commodities in addition to the *costuma magna et antiqua*. Thus, 30,000 sacks of wool were granted to Edward III. in 1340, in aid of the war with France. Subsidies were granted on various occasions to James I. and Charles II. 2. The same word is used to denote money paid by one state to another, in order to procure a limited succour of auxiliary troops, ships of war, or provisions. In the time of the war with the revolutionists of France and Napoleon I., Great Britain furnished subsidies to foreign powers to a large extent, in order to engage them to resist the progress of the French. In questions regarding subsidies, it is held that the state furnishing the succour does not thereby become the enemy of the opposite belligerent: it may remain neutral in all respects, except as regards the auxiliary forces supplied. Such, for example, was long the attitude maintained by the Confederate Cantons of Switzerland: while granting troops to the various European powers, they were in the habit at the same time, of preserving a rigorous neutrality. The service of Swiss regiments abroad is no longer sanctioned. The federal constitution of Switzerland, of 12th September

1848, prohibited the conclusion of military capitulations, and on 30th July 1859, a proclamation was issued by the Federal Council, forbidding any Swiss subjects from taking service under a foreign power, without the authorisation of the council.

SUBSTANCE, a word connected with certain discussions in Logic and Metaphysics. Substance is correlative with Quality or Attribute. Every substance must have attributes, and every attribute must be the attribute of some substance. The substance gold has the attributes weight, colour, &c. But as every power or property of a thing, every way that the thing affects us, may be called an attribute or quality, if all the attributes are counted off, there is nothing left; and the question then arises: What is the *substance?* To avoid this seeming inconsistency, it was assumed that everything whatsoever possesses, besides its attributes, an unknown substratum that they rest upon, or inhere in—a mystical and inscrutable bond, that holds the attributes together, without being itself an attribute. This gratuitous assumption of what is, after all, a nonentity, was repudiated by Locke and others, who found a meaning for substance without departing from the knowable. Every object has some *essential* or *fundamental* quality, which being present, it preserves its identity; and which being removed, it is no longer the same object, but another. Thus, the substance of Body or Matter is not the remnant after all the qualities are subtracted; it is the two fundamental and inerasable qualities, Extension and Resistance. Size, shape, colour, heat, odour, &c., may all be varied; but so long as Extension and Resistance, in any degree, are found, we have a piece of matter. On the same view, the substance of Mind is whatever we regard as its fundamental essence, or distinguishing marks. We may adopt Feeling, or Volition, or Intellect, or require a share of all three, according to our mode of defining the mind. It would, then, be a mere confusion of language to talk of Feeling, Volition, and Intellect as *inhering* in mind; they *are* mind, and there is nothing besides.

Notwithstanding the obviousness of this explanation, the employment of the words Substance and Attribute has led to such an inveterate demand for something that shall underlie all attributes—a substance of body, and a substance of mind—distinct from anything meant by the names, that many philosophers have considered it necessary to preserve the phantom as a thing of belief, if not of knowledge. The doctrine of an unknowable substance in the abstract very early allied itself with the popular theory of the Perception of a material world (see PERCEPTION), and the same arguments are good, for or against both. Other names for expressing the same contrast are *noumenon* and *phenomenon*. The Phenomenon is what shews itself to our senses, or is conceived by our intelligence—the qualities of extension and resistance in body; and of feeling, &c., in mind. The Noumenon is something apart and beyond, something inconceivable and unknowable, but which, say some, we are instinctively led to believe in. Thus, in the great question above alluded to—the belief of an independent material world—the phenomenal manifestations are inextricably involved with our mental powers of conceiving, and would vary, if these were to vary; consequently, they cannot be the absolute, independent, self-existent reality; which drives one school of philosophy upon the expedient of believing in such a reality, although it must be for ever incomprehensible to us.

SU'BSTITUTE, MILITARY. In nations where conscription is resorted to for the supply of soldiers for the army, the lot often falls on those unwilling to serve in person. In such a case, the state agrees to accept the services of a substitute—that is, of a person of equally good physique. Unless the levy be very extensive, or the term of military service very long, substitutes are readily found among military men who have already served their prescribed period. Of course, the substitute must be paid for the risk he runs. His price depends, like all other saleable articles, on the demand and supply. Happily, in Great Britain, few of those now living have ever known when substitutes were necessary. It is, however, to be remembered that the act for a militia ballot hangs continually over us, and is only suspended by a special act of parliament from year to year.

SUBSTITU'TION is one of the three principal methods employed in examining the chemical composition of organic bodies, and in tracing their relation to other compounds; the two other methods being those of *oxidation* and of *reduction*. Although the term is restricted to organic chemistry, the ordinary method of preparing insoluble inorganic compounds by double decomposition is in reality a case of substitution of one base or one acid for another. If, for instance, solutions of nitrate of lime and sulphate of soda are mixed together, the resulting compounds are sulphate of lime and nitrate of soda, in which the lime is substituted for the soda, and the soda for the lime. In some cases, an element may be replaced (or, more correctly, displaced) by a compound group; thus, cyanogen, CN or Cy, may take the place of oxygen, as, for example, in the reaction that ensues between hydrocyanic acid and red oxide of mercury, when cyanide of mercury and water are formed, as shewn in the equation: $H(CN) + Hg_2O = Hg_2(CN) + HO$. Similarly, the groups NO_4, SO_2, and NH_2 may often be substituted for hydrogen. In various organic bodies, one or more atoms of hydrogen may be displaced by one or more atoms of chlorine, a fact which was originally observed by Gay-Lussac in noticing the action of chlorine on wax. The new product thus formed is almost always analogous in its nature to the compound from which it is produced; thus, according as the substance acted on by the chlorine is an acid or a base, the resulting product is an acid or a base, and the number of atoms is always the same in the original substance and the product. The following examples will elucidate the above remarks: If acetic acid, $C_2H_4O_2$, be exposed to the action of chlorine, we obtain, according to the duration and modifications of the action, the two compounds, monochloracetic acid, $C_2H_3ClO_2$, and trichloracetic acid, $C_2HCl_3O_2$, in the former of which, one atom, and in the latter, three atoms, of hydrogen, are displaced by a corresponding number of atoms of chlorine. Hydrochloric ether, $C_2H_5.Cl$, may be made to yield the following succession of compounds, in which a gradually increasing amount of the hydrogen is displaced by chlorine, until, in the final result, the hydrogen has altogether disappeared. The consecutive compounds thus resulting from hydrochloric ether, $C_2H_5.Cl$, are (1) chlorinated ether, $C_2(H_4Cl)Cl$; (2) dichlorinated ether, $C_2(H_3Cl_2)Cl$; (3) trichlorinated ether, $C_2(H_2Cl_3)Cl$; (4) tetrachlorinated ether, $C_2(HCl_4)Cl$; and (5) sesquichloride of carbon, $C_2(Cl_5)Cl$. 'The chlorine,' says Professor Miller, 'appears to have taken the place of hydrogen in the group without disturbing the relative position of the other elements which enter into its formation; just as a brick in an edifice may be conceived to admit of being renewed, whilst its place is supplied by a block of wood or of stone, without altering the form or symmetry of the building.' Substitutions of

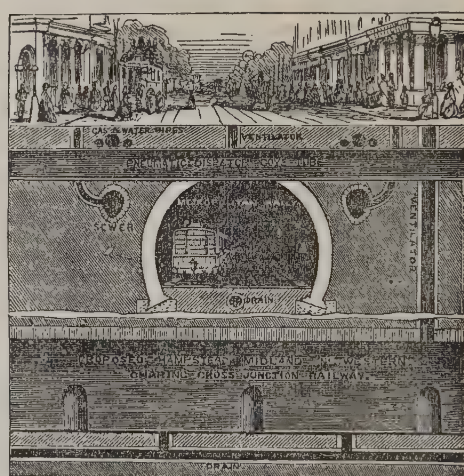
bromine and iodine for hydrogen may be effected in the same way as has been shewn to occur in the case of chlorine. The study of the artificial formation of organic bases has led to the discovery of many remarkable instances of substitution products. If, for example, bromide of ethyl, C_2H_5Br, be heated in a sealed tube with a solution of ammonia in alcohol, hydrobromate of ethylia (or ethylamine) will be formed, and on distilling the vapour with hydrate of potash, one of the products will be a new base, ethylamine, C_2H_7N, which may be regarded as ammonia, NH_3, in which one atom of hydrogen has been displaced by one atom of ethyl, C_2H_5. By a similar proceeding, we may successively displace the second and the third atoms of the hydrogen in the ammonia; and we thus obtain two more complex bases, diethylamine, $C_4H_{11}N$, and triethylamine, $C_6H_{15}N$.

SUBTRA'CTION, one of the four fundamental processes of Arithmetic, is the diminution of a quantity by the removal of a certain portion of it. It is consequently the reverse of *Addition*, and determines how much of any quantity remains after a certain quantity has been taken from it. In cases where the digits of the number to be subtracted are greater than the corresponding ones of the number to be diminished, two methods of operation may be adopted.

(1)	(2)	(3)
7324	7 (13) (12) 4	6 (12) (12) 4
1842	(2) (9) 4 2	1 8 4 2
5482	5 4 8 2	5 4 8 2

For example, in subtracting 1842 from 7324, the numbers are written as in form (1). The method of operation usually followed is to make an addition mentally to the upper figure when necessary, and then compensate for this by an equivalent addition to the next under figure, as represented in form (2). Thus, 10 'tens' are added to 2 'tens,' to enable 4 'tens' to be subtracted, and this addition is compensated for by an equal increase of the under line by 1 'hundred,' through the change of 8 'hundreds' into 9 'hundreds.' The more simple and directly intelligible plan, shewn in form (3), is to borrow a unit of the next higher degree in the upper line, care being taken to remember, in the partial subtraction immediately succeeding, that the upper digit must be considered as less by unity than it appears.

SUBWAYS. The system of engineering *beneath* the public streets has not by any means yet reached its full development. The Metropolitan or Underground Railway, opened in 1863, was the first example of its kind; the passengers going down stairs from the side-pavements to stations underneath the carriage-way. The pneumatic propulsion of mail-bags (see PNEUMATIC DISPATCH) has given rise to projects for a similar mode of propelling railway trains beneath streets and roads. One such, the Waterloo and Whitehall Railway, was commenced about 1865 to pass under the Thames; want of funds led to its abandonment after shafts had been sunk. But the term *subways* is usually applied, not to such tunnelled passages for travelling, but to roomy archways that will contain sewer-pipes, water-pipes, and gas-pipes. It has been long considered a defective system that whenever such pipes need repair, the surface of the street has to be broken up to get at them, thereby causing great expense and great interruption to traffic. When the Metropolitan Board of Works commenced their series of improvements, they resolved on the trial of subways for this useful purpose. They began with a new street, extending from Covent Garden Market to St Martin's Lane, opened in 1861. Underneath the carriage-way on this street, there is a subway, a central arched passage or tunnel 12 feet wide by 6½ feet high; with arched side-openings, for house service-pipes, connected with the cellarage of the several dwellings. In this subway are water-pipes, gas-pipes, and electro-telegraphic wires, all easy of access by side entrances to the subway, of sufficient size to admit workmen, pipes, &c. In this instance, the main sewer is not in the subway itself, but underneath it, provided with man-holes, gullies, ventilating shafts, &c. The improvement was long delayed on account of doubts entertained as to whether the ventilation would be sufficient to overcome the dangers arising from the leakage of the gas-pipes; and there can be



Section of Underground Works at the Junction of Hampstead Road, Euston Road, and Tottenham Court Road.

(From *Illustrated London News.*)

no doubt that care will be needed in making and sealing the pipe-joints. A second example is afforded by Southwark Street, a noble new street, lately formed from Blackfriars Road to the southern foot of London Bridge. Underneath this street extends a subway, excellently planned for the purposes above mentioned. Two street lamp-posts, of unusually elegant design, one at each end of the bridge, act as ventilating shafts for the subway; and there are other ventilators along the route, besides side entrances for workmen. A curious proof has been furnished, however, of the anomalies which so frequently mar our public works. In 1865, a gas company broke up the roadway, and broke through the well-built crown of the arch of the subway, to get at their gas-pipes for purposes of repair or adjustment. It was found, on investigation, that no one had power to prevent them. The act empowered the Metropolitan Board of Works to make a subway for the use of gas companies, water companies, &c.; the gas company, on the other hand, were empowered by *their* act to break up the public roadways to get at their pipes; the Board could not compel the company to adopt the new plan, because the powers were only permissive, not obligatory. Thus, a useful reform was rendered in part nugatory by a bungling in the preparation of an act of parliament. It is to be hoped that two new streets sanctioned, and likely to be proceeded with in 1867 and later years, from Blackfriars Bridge to Cannon Street, and from Tottenham Court Road to Charing Cross, will have subways

better guarded against such absurd anomalies. The water companies and gas companies fear incurring additional expense; and there is known to be a difference of opinion among engineers concerning the danger from leakage and explosion when the two sets of pipes are enclosed in the same archway. The system is likely to receive a fair trial in some provincial towns, where the gas and water arrangements are not so complex as in the metropolis. An important subway was constructed in 1866 in connection with the Thames Embankment from Westminster to Blackfriars. Indeed, between the masonry of the river-wall and the present line of high water, there will be no less than three tunnels or arched passages under the surface of the ground. One will be the Metropolitan District Railway, in its course from the east to the west of London; another will be the Low Level Sewer of Great Main Drainage System, to join the outfall at Old Ford; while a third will be a subway to contain gas and water pipes, telegraph wires, &c. Most of these brick tunnels will be in newly-made ground, on a site which, until recently, was twice daily covered with the tidal waters of the Thames. And not only so, but another subway or tunnel will pass underneath and at right angles to all these three, to carry the Middlesex end of the Whitehall and Waterloo Railway, already mentioned. Very careful engineering is required in these extraordinary works.

SUCCE'SSION is a legal term used in Scotland, but not used technically in England, where the same subject is spoken of under the name of Next of Kin (q. v.), and Descent; see also INTESTACY, STATUTE OF DISTRIBUTIONS, EXECUTORS, ADMINISTRATOR. In Scotland, the term is used to denote the taking of property by one party in place of another. Where the devolution takes place in consequence of a conveyance from the proprietor, the acquirer is termed a singular successor, as the conveyance is the single title under which he acquires. Where, however, the person dies intestate, his heir succeeds to the whole of the heritage, and is called the universal successor. Where no will or disposition by the owner is executed, the law makes a disposition for him, and distributes the property according to certain rules of relationship by blood. 1. In the case of heritable succession, Primogeniture (q. v.) is the rule, the eldest son and his issue taking the property; and after that stock is exhausted, the next eldest son; and so on. When males fail, then the succession opens to the daughters, who take not in order of seniority, but all together, and are called Heirs-portioners (q. v.). When descendants fail, then the succession goes to collaterals; thus, brothers and sisters succeed first—the brothers according to a certain priority, and, failing them, the sisters all together as heirs-portioners. When the descendants and collaterals are exhausted, the succession then goes to ascendants (the mother, however, being entirely excluded), the father first, and then uncles and aunts, &c. In heritable succession, the right of representation exists, i. e., when an heir is dead, his children represent him, and take that share which, if alive, he would have taken. Brothers and sisters consanguinean, i. e., by the same father, but not by the same mother, succeed after brothers and sisters german (i. e., by the same father and mother), before the remoter line of the full blood. The English law of descent or succession differs considerably from the above. See INTESTACY, and Paterson's *Comp. of English and Scotch Law* (2d ed.), s. 751, *et seq.*—2. As to succession in movables, or to the personal property of the intestate, see NEXT OF KIN. There are taxes called succession duties, which are payable to the revenue on all property, real and personal, acquired by succession The duty payable on lineal issue or lineal ancestors is 1 per cent.; by brothers and sisters and their descendants, 3 per cent.; and so on, the duty increasing as the relationship is more distant. The husband or wife of the proprietor is exempted from the duty.

SUCCESSION ACTS. From a comparatively early period in English history, parliament occasionally exercised the power of limiting or modifying the hereditary succession to the throne. The first instance of such interference occurred in the reign of Henry IV., who possessed himself of the crown, to the prejudice of the descendants of Lionel, Duke of Clarence, second son of Edward III. Act 7 Henry IV. c. 2 confirmed the title of that monarch, and declared Prince Henry heir-apparent of England and France, with remainders to Henry IV.'s other children. Parliamentary interposition was subsequently exercised in the case of Henry VII. and in regard to the immediate successors of Henry VIII. The respective rights of James I., Charles I., and Charles II. were acknowledged by parliament; and in the case of Charles II. the crown was held to have devolved on him immediately on the death of his father.

The revolution of 1688 was founded on the so-called abdication of the government by James II. See ABDICATION. The Convention bestowed the crown on William and Mary for life, and regulated the claims of Anne. On the impending extinction of the Protestant descendants of Charles I., the crown was settled by 12 and 13 Will. III. c. 2, in the event of the death of William and Anne without issue, on the next Protestant line, according to the regular order of succession—viz., the descendants of the Electress Sophia of Hanover, granddaughter of James I.; and it was at the same time enacted, that whoever should hereafter come to possession of the crown, should join the communion of the Church of England as by law established. This is the latest parliamentary limitation of the crown; but the right of parliament to limit the succession has been secured by 6 Anne, c. 7, which attaches the penalties of treason to the 'maliciously, advisedly, and directly' maintaining, by writing or printing, that the king and parliament cannot make laws to bind the succession to the crown, and the penalties of a *Præmunire* (q. v.) to maintaining the same doctrine by preaching, teaching, or advised speaking.

SUCCESSION WARS were of frequent occurrence in Europe, between the middle of the 17th and the middle of the 18th centuries, on the occasion of the failure of a sovereign house. The most important of these wars was that of the Orleans succession to the Palatinate (1686—1697), closed by the peace of Ryswick; of the Spanish succession (1700—1713); of the Polish succession (1733—1738), closed by the peace of Vienna; of the Austrian succession (1740—1748); and of the Bavarian succession (1777—1779), called, in ridicule, the Potato-war. Of these, the second and fourth were by far the most important, and a brief notice of their course and conclusion is subjoined.

SUCCESSION, WAR OF THE SPANISH, arose on the death, without issue or collateral male heirs, of Charles II., king of Spain, 3d November 1700. The nearest natural heir to the throne was of the royal line of France, Charles's elder sister having married Louis XIV.; but to prevent any possible union of the two crowns, a solemn renunciation had been exacted both from Louis and his queen, for themselves *and their heirs*; and this renunciation having been ratified by the king and Cortes of Spain, was made as binding as legal forms could make it

Failing the Bourbons, the next heirs were the descendants of the younger sister of Charles, who had married the Emperor Leopold I., and from whom no renunciation had been exacted; and the only issue being a daughter, who had married the Elector of Bavaria, and borne a son, Joseph-Ferdinand, this prince was during his lifetime regarded both by Charles II. and the Spanish people as the rightful heir. But dying in 1699 without issue, the question of succession was reopened, Louis XIV., failing his wife's rights, claiming for himself, as the son of Philip IV.'s elder sister (being, however, again legally barred here by another solemn renunciation); while the Emperor Leopold, maintaining with justice that the Bourbons were by these two renunciations wholly deprived of all their rights of heirship, claimed the throne as the son of Philip IV.'s younger sister. The other powers of Europe, especially Britain, Holland, and Germany, warmly interested themselves in the matter, as a question of policy, and with good reason; for not only was the crown of Spain a valuable prize in itself, carrying with it the sovereignty of the Netherlands, the Milanese, Naples and Sicily, and immense possessions in America, but its union with France or Austria would of a certainty endanger the independence of every other sovereignty in Europe. Both claimants bade for the support of the maritime powers, the one by renouncing his claims in favour of his second grandson, Philip of Anjou, the other by putting forward his second son, Charles, as his substitute, while both solemnly promised never to undertake the union of the two crowns. The Austrian party at first preponderated in Spain; but Louis, by able and unscrupulous policy, succeeded in undermining the Austrian influence at Madrid, and in having Philip declared the heir (October 2, 1700). On the death of King Charles, a month after, Philip appeared in Spain, and was well received by all classes, and at once recognised as monarch, an example gradually and unwillingly followed by all the European powers excepting the emperor; for at that time the dread of Louis XIV.'s power pressed like an incubus on the nations of Europe. However, the French monarch, by various ill-advised acts, chiefly by his support of the elder Pretender (the son of James II.), whom he recognised as sovereign of Britain, and by occupation of the Netherlands and menacing treatment of Holland, stirred up such general resentment, that William III. was enabled to revive the *Grand Alliance*, and his successor, Anne, to join with Holland and Austria in declaring war against France and the 'Spanish usurper,' 15th May 1702.

Hostilities at once commenced: a combined British-Dutch-German army under Marlborough attacked the French in Belgium, and captured one by one their fortresses on the Maes, while the Reichs army (Germany having declared for Austria), under the Markgraf of Baden, crossed the Rhine, and took Landau. Austria herself had, however, commenced the contest in the previous year, by sending into Italy Prince Eugene (q. v.) of Savoy-Carignan at the head of a veteran army of 32,000 men, who did a good deal of hard fighting, with no adequate result. Meanwhile, the Elector of Bavaria raised an army and declared for France, and a French army under Villars marched to join him. Both were kept in check by the Markgraf for some time; but, in the summer of 1703, Villars burst through the Black Forest, and joined the elector, with the view of penetrating through Bavaria into Austria, but his obstinate ally, the elector, was determined to invade the Tyrol instead, and join Vendome in Northern Italy—a scheme which ended most disastrously; and Villars returned in disgust to France. In the Low Countries, Marlborough employed himself in gradually depriving the French of their strongholds: and in Italy, the Austrians were driven from point to point, till nothing remained to them but a few districts on each side of the Po; they were, however, relieved towards the close of the year by the defection of the Duke of Savoy, who joined the grand alliance 25th October 1703, an event which compelled Vendome to return to Piedmont. The first great blow was struck in the following year, when the combined Austrian-German-British army, under Marlborough, totally defeated the French and the elector at Blenheim (q. v.), driving the débris of their forces almost to the foot of the Vosges. After this, the French never obtained a permanent footing in Germany. The campaigns of Marlborough in Germany, and of Eugene in Italy, in 1705, were successful but not very important. The year 1706 was another great epoch in this protracted contest; the British and Dutch having freed the valley of the Maes, had forced the French into South Brabant, and Marlborough having, by a stratagem, caused them to march towards Namur, suddenly attacked them at Ramillies (q. v.), and, after a brief combat, put them completely to rout with great slaughter, the elector and Villeroy, the joint commanders, narrowly escaping capture. Louis hastily reinforced his army, and recalled Vendome from Italy to take the command, a step which, however necessary, cleared the way for Eugene, who completely out-generalled his opponent Marsin, and after a memorable march of 34 days, appeared before Turin, and united with the Duke of Savoy. The battle of Turin, in which the gallant Marsin was slain, was one of the most obstinate of the whole war, but its result was as decisive, and from this period the French power in Northern Italy was shattered; and the following year saw the country completely cleared of both French and Spaniards. From 1706 the war in Germany was purely defensive, and no battle worthy of notice was fought. In Italy also the contest on the whole languished, though the Austrian arms were for the most part successful, Mantua and Naples (1708) being subdued, and the pope compelled to preserve neutrality by dread of another sack of Rome. But since the commencement of 1704, another theatre of war had been established by the landing of the Archduke Charles at Lisbon with 8000 British and 6000 Dutch troops, who were joined by the Portuguese (their king having acceded to the alliance against France), and invaded Spain from the west; but nothing of consequence was accomplished till a landing had been effected by the Earl of Peterborough (q. v.), with a small body of troops, in Catalonia. Then attacked both from the west and east, the Bourbon forces were beaten and driven across the Pyrenees, and it was only after the departure of Peterborough that Berwick (q. v.) made head against his antagonists. By his victory at Almanza (25th April 1707), he recovered the whole of Spain except Catalonia. In 1710 Berwick finally left Spain; and the Carlists under Stanhope and Starhemberg again got the upper hand, repossessing themselves of the east of Spain, and of Madrid (28th September). But the arrival of Vendome speedily changed the face of affairs. Stanhope was defeated and captured (9th December) at Brihuega, and Starhemberg was forced to retreat on the following day. The war was thenceforth confined to Catalonia, and was distinguished by no noteworthy incidents. The most important part of the struggle had been meanwhile taking place in the Netherlands, where Marlborough (1707) drew up in concert with Eugene a secret plan of operations which effected a division of the Moselle army under the elector and Berwick from that of the north

under Vendome; whereupon the British and Germans swiftly uniting fell upon Vendome's army at Oudenarde (q. v.) (1708), and before Berwick could come up to its aid, inflicted upon it a severe defeat. The capture of Lille, Ghent, and Bruges necessarily followed. France now began to show symptoms of exhaustion, and made overtures of peace, but these being chiefly illusory, were rejected; and the emperor having largely reinforced Eugene, the allies took the field with 110,000 men, while the French, equal in strength, were now directed by Villars, the most enterprising and fortunate of their generals; but his star, which had hitherto been constantly in the ascendant, fell before that of Marlborough at Malplaquet (q. v.) (September 1709). After some further campaigning, besieging, and negotiating, the opportune death of the emperor (April 17, 1711) rescued France from the brink of destruction; for Britain became immediately lukewarm in support of a cause which would effect the reunion of Austria and Spain; and the Tories having come into power, private preliminaries of peace were signed between Britain and France, 8th October 1711. Eugene, however, continued the war, aided by Holland, and captured Quesnoy; but the defeat and capture of the Earl of Albemarle and the British contingent at Denain (July 1712) so weakened his force, that he was compelled to give way; and in the following spring the Dutch joined the British as parties to the peace of Utrecht (q. v.). The Emperor Charles was also forced to conclude a treaty of peace at Baden, 7th September 1714, which ended the struggle, leaving Philip in possession of the Spanish throne (see UTRECHT, PEACE OF); while Austria obtained the Spanish Netherlands and the Milanese.

SUCCESSION, WAR OF THE AUSTRIAN. The death of the Emperor Charles VI. (20th October 1740), by which the male line of the House of Hapsburg became extinct, was the signal for a general uprising of the powers of Europe, some to prey on the Austrian possessions, and others to aid the eldest daughter and heir of the deceased emperor. The probability of such a contingency had long been foreseen by Charles VI., for as early as 1713 he had published a *Pragmatic Sanction* (q. v.), stipulating that, in default of male heirs, the whole of his dominions should descend undivided to his eldest daughter, Maria Theresa (q. v.); and it was almost his sole aim, during his subsequent reign, to gain the consent of all parties having proximate claims to any of the Austrian domains, and of the principal powers of Europe, to this arrangement. The Elector of Bavaria, Charles-Albert, alone refused to resign his pretensions. On the death of her father, Maria Theresa intimated her accession to the various European powers, and from all of them, except France and Bavaria, received assurances of good-will and support; but notwithstanding, two months did not elapse till Frederick II. of Prussia, without a declaration of war, invaded Silesia. The Austrian treasury was at this time exhausted, and the army much disorganised; so that little or no effective resistance could be made to the Prussians; while the state of alarm into which this sudden attack had thrown the court of Vienna was increased by doubts as to the intentions of France. These doubts were soon resolved by the latter, in the spring of 1741, forming a confederacy of all the claimants to the Austrian dominions—the electors of Bavaria and Saxony, sons-in-law of the Emperor Joseph I.; Philip V. of Spain; Charles-Emanuel of Sardinia, who claimed the Milanese; and Frederick II. of Prussia, who *now* demanded almost the whole of Silesia. On the other hand, Britain granted Maria Theresa an annual subsidy of £300,000; the Dutch were willing to aid her when opportunity offered; and Hungary gallantly responded to her pathetic appeal by sending in thousands her motley population, Magyars, Croats, Slavs, and Tolpatches, to fight in defence of their heroic queen. Meantime the Bavarians, in conjunction with the French under Belleisle, overran the greater part of Bohemia. This invasion compelled the queen to buy off her most formidable opponent, Prussia, by the surrender of Silesia and Glatz; and then, while Prince Charles of Lorraine kept the French at bay in Bohemia, Khevenhuller, the most enterprising of the Austrian generals, advanced up the valley of the Danube, captured 12,000 French in Lintz, overran Bavaria, and on the very day of the elector's coronation as the Emperor Charles VII., took Munich his capital (12th February 1742). But this great success alarmed Frederick II. for the security of his new possessions, and abruptly breaking the treaty, he poured his forces into Bohemia and Upper Austria, and gained the battle of Chotusitz (17th May). The same year witnessed increased activity on the part of Britain (the Walpole administration being now in power) and Holland on behalf of Austria; the expulsion of the French and Bavarians from Bohemia; the severance of the king of Sardinia from the coalition against Austria, produced by the bribe of some districts of the Milanese, which, however, he did not obtain till some time afterwards; the enforcement of neutrality upon Naples by the threatening attitude of a British fleet off the capital; and, on the other hand, the recovery of Bavaria by the elector.

In May 1743, Bavaria again fell into the hands of Prince Charles and Khevenhuller; Count Saxe was driven with great loss from the Palatinate; the 'Emperor' Charles-Albert and the Swedes, disgusted at their ill-success in the war, retired from the contest, so that France and Spain now remained the sole representatives of the once mighty coalition. In 1744, France and Britain, which had hitherto engaged in the conflict only as allies, declared war on each other; and the latter proceeded to destroy piecemeal the French and Spanish shipping on the high seas, and to attack their colonial possessions. For this, however, the successes of Saxe in the Netherlands were a compensation. However, the great successes of Austria on the Rhine, and the ill-concealed ambitious projects of Maria Theresa, again alarmed Frederick II. for Silesia; and he resolved on another attempt to rivet his hold on the much-coveted province before it was too late. Accordingly, he concluded at Frankfurt (May 13, 1744), a secret convention with France, the emperor, the elector-palatine, and the king of Sweden. Bursting into Bohemia with his usual celerity, Frederick II. forced the Austrians at once to return from Alsace, thus enabling the elector to recapture Bavaria; but before Prince Charles had time to reach Bohemia, a fresh levy of 44,000 men, which had been raised by the chivalrous and patriotic Hungarians, joined by 6000 Saxons, had reached the Prussians, and by cutting off their supplies, and capturing their stragglers and foraging parties, compelled them to evacuate the kingdom with considerable loss. In Italy, the Spaniards, who were now joined by the Neapolitans, were defeated repeatedly, and compelled to retreat down the peninsula; and the king of Sardinia succeeded in preventing the French from effecting a permanent lodgment in North-west Italy. In January 1745, the emperor-elector died, and his son, Maximilian-Joseph, profiting from his father's misfortunes, declined to take part in the contest, or to allow himself to be nominated emperor, and made peace with Austria. Frederick II., displeased with the meddling and overbearing conduct of France

with respect to the approaching imperial election, also sought to come to terms with Austria, by the mediation of Britain, and the peace of Dresden (25th December 1745) finally withdrew Prussia from the conflict. In Flanders, the fortunes of Austria also declined; and after the victory of Fontenoy (11th May 1745) she could not prevent Saxe from capturing the chief Belgian fortresses in succession. In Italy, also, fortune declared for the coalition; for the Spanish-Neapolitan army, now reinforced by the Genoese and Modenese—70,000 men in all—defied all opposition, overran the whole of Lombardy and much of the Sardinian territories, driving the king under the walls of his capital. Similar reverses befel the allies in Flanders during the campaign of 1746; but these were more than counterbalanced by the great successes obtained in Italy, where all the lost fortresses of Lombardy, Parma, and Guastalla, were recaptured, the coalition army totally routed in a great battle near Placentia (June 16), and Genoa overrun and occupied. Another of fortune's favours to Austria was the death of Philip V. of Spain (July 9), which, by depriving that arch-plotter, his queen, of the supreme power, considerably diminished the zeal of the Spanish court in the prosecution of the war. In 1747, the Dutch, who had hitherto escaped the ravages of war, were made practically acquainted with them by Saxe, who, having completely subdued the Austrian Netherlands, invaded and overran Dutch Flanders, routed the unfortunate Duke of Cumberland at Laffeldt (2d July), while his celebrated chief of engineers, Count Lowendal, after a two months' siege, took Bergen-op-Zoom, Cohorn's masterpiece, a fortress believed by the Dutch to be impregnable. At the commencement of 1748, Britain, France, and Holland sought to bring about a peace, and agreed among themselves to certain preliminaries, which were submitted to Austria and Sardinia; but as one of them was the surrender of Parma and Placentia to Don Philip of Spain, the former refused her consent; and her two allies, disgusted at her disregard of the sacrifices they had made on her behalf, at once signed the preliminaries (30th April), and Austria sullenly followed suit on May 18. Much discussion followed, but on the 18th October 1748, the treaty of Aix-la-Chapelle (q. v.) put an end to this most disastrous war, which left the Hapsburgs in possession of their hereditary dominions, with the exception of Silesia and some of their Italian provinces. See AIX-LA-CHAPELLE.

SUCCI'NIC ACID ($C_4H_6O_4$) derives its name from its having been originally found in amber (Lat. *succinum*), and is one of the group of dibasic acids of the oxalic acid series, whose general formula is $C_nH_{(2n-2)}O_4$. Succinic acid occurs as a natural constituent not only in amber, but also in the resins of many of the pine tribe, in the leaves of the lettuce and wormwood; and, in the animal kingdom, it has been detected in the fluids of hydatid cysts and hydrocele, in the parenchymatous juices of the thymus gland of the calf, and of the pancreas and thyroid gland of the ox.

One of the most important points in connection with succinic acid is its convertibility into tartaric acid, while tartaric acid may in its turn be reconverted into succinic acid.

SU'CCULENT PLANTS are those plants remarkable for the thick and fleshy or succulent character of their stems and leaves. This character prevails in the natural orders *Cactaceæ*, *Mesembryaceæ*, and *Crassulaceæ*, but frequently appears also in genera of other natural orders, as in aloes and some other *Liliaceæ*. It consists in a peculiar development of cellular tissue. Succulent plants are remarkable for the small number of Stomata (q. v.) on the green surface. They are generally found in dry climates, often as almost the only vegetation of the most arid places; although some of them occur in situations where moisture is often abundant; their peculiar structure, however, being apparently intended to adapt them for enduring occasional droughts. Thus, there are not only succulent plants in the Sahara and other deserts, but in Britain, and some of them form a conspicuous feature of the flora of the mountains of Europe—as species of *Sedum*, *Rhodiola rosea*, &c.—where they are found in situations sometimes abounding in moisture, but occasionally parched—on bare rocks, steep slopes with scanty soil, and the like. By the want of stomata and the store of moisture in their own cellular tissue, they are adapted for the endurance of long droughts. Yet they live in great part by nourishment derived from the atmosphere, rather than from the soil; a fact which may easily be proved by suspending a specimen of the Common Yellow Stonecrop (*Sedum acre*) by means of a string, when it will be found to flourish for a considerable time, and sometimes to preserve its vitality as long as those planted in the ground. In dry tropical countries, succulent plants perform in part the same office which lichens and mosses do in colder regions, in preparing the first mould for future vegetation.

SUCHET, LOUIS-GABRIEL, Duke of Albufera, and Marshal of France, was descended from an honourable family, and born at Lyon, 2d March 1770. He volunteered as a private into the cavalry of the Lyon national guard in 1792, and subsequently became attached to the army of Italy. His rare intelligence and brilliant valour, displayed at Lodi, Rivoli, Castiglione, Arcola, and in numerous battles of less note, laid the foundation of his military reputation, and in 1798 he became general of brigade. The able manner in which he, with a force not one-sixth of that of the Austrians, kept Melas in check (1800), preventing the invasion of the south of France, and ultimately capturing 15,000 prisoners, is one of the most brilliant military feats on record. S. also took a distinguished part in the campaigns against Austria (1805) and Prussia (1806), and was subsequently (April 1809) appointed generalissimo of the French army in Aragon, where, for the first time, he appears as holding an independent command. The part of Spain committed to his charge, though inhabited by a people distinguished by their obstinacy and patriotism above all others in Spain, was completely subdued, more, however, through his just and able administration, and the strict discipline which he maintained, than by military talent. The latter quality he was only called upon to exercise against Spanish troops, which he had little difficulty in annihilating. In the first few days of 1812, he conquered Valencia, and obtained in addition to his dignity of Marshal (8th July 1811) that of Duke of Albufera, and the grant of a magnificent domain. The five campaigns which he made in the Peninsula are considered perfect models of the kind of service he had to perform—viz., to rivet the chains of a foreign domination on the necks of a patriotic and high-spirited people. The details have been well given by him in his *Mémoires sur ses Campagnes en Espagne* (Paris, 1829, 1834, 2 vols. with atlas). But the misfortunes of the other French armies in Spain compelled S. gradually to relinquish all his conquests. He was created a peer by Louis XVIII., but took service under his old master after his return from Elba, and was charged with the defence of the south-west frontier. Deprived of his peerage at the second restoration, he did not return to court till 1819, when it was restored, and he soon rose high in royal

favour. He died at the château of Saint-Joseph, near Marseille, 3d January 1826. Napoleon's high opinion of S.'s military talents is recorded by O'Meara and Las Casas, and according to his classification, S. ranked second, Massena being first.—His son and successor in the dukedom of Albufera is a member of the Corps Legislatif, and a supporter of the Napoleonist policy.

SUCKING FISH, a name sometimes given to the Remora (q. v.), and to fishes of the family Discoboli (q. v.), which have a sucker formed by the union of the ventral fins, and are capable of attaching themselves by it to stones or other substances. The best known of the British species, and the only one which is of any value as an article of food, is the Lumpsucker (q. v.). Several other species occur on the British coasts, to which the name SUCKER is generally given, as the CORNISH SUCKER (*Lepidogaster Cornubiensis*), and the UNCTUOUS SUCKER or Sea-snail (*Liparis vulgaris*). They are small fishes, destitute of scales.

SUCKLING, SIR JOHN, one of the brilliant cavalier poets of the court of Charles I., was born at Whitton, in Middlesex, and baptised February 10, 1608—1609. His father, also a knight, held office as a secretary of state, and comptroller of the household, but died in 1627, when the poet was in his 18th year. The latter inherited large estates; and having completed his education at Trinity College, Cambridge, he went abroad, and served for some time in Germany under Gustavus Adolphus. He returned about 1632, and was soon distinguished for his wit, gallantry, and lavish expenditure. To aid the king against the Scots, he raised a troop of 100 horsemen, whom he clad in a rich and gaudy uniform of white and red, with plumes of red feathers in their caps. This loyal corps is said to have cost the poet about £12,000. They rode north; but no sooner had the cavalry come within sight of the Scots army at Dunse, than they turned and fled without aiming a blow! This disgrace gave occasion to numerous lampoons, and to a clever though coarse ballad against S.'s gay horsemen; but in reality they behaved no worse than the rest of the English army. Their loyal commander next joined in a scheme to rescue Strafford from the Tower, and this being discovered, he fled for safety to the continent. He died, while yet in the flower of his life and genius, in 1641 or 1642. Various accounts are given of the circumstances attending his death, but the most painful of these, viz., that he poisoned himself in Paris, is confirmed by family tradition. See the Memoir by the Rev. Alfred Suckling (1836), prefixed to a volume of *Selections from the Works of Sir John Suckling*. He had probably run through his fortune, and dreaded want, as well as despaired of the success of the royal arms. The works of S. consist of four plays, now utterly forgotten, a prose treatise entitled *An Account of Religion by Reason*; a collection of *Letters*, written in a stiff, artificial style; and a series of miscellaneous poems, beginning with *A Session of the Poets*, published in 1637, which is original in style, and happily descriptive of the author's contemporaries. But the fame of S. rests on his songs and ballads, which are inimitable for their ease, gaiety, and pure poetic diction. A few pages of amatory lyrics have embalmed his name for all posterity. His ballad of *The Wedding* is still unsurpassed, and one simile in his description of the bride—

> Her feet beneath her petticoat,
> Like little mice, stole in and out,
> As if they feared the light—

has had the honour of being copied by Herrick and Congreve.

SUCTO'RIA, an order of insects, containing only those which formed the Linnæan genus *Pulex*. See FLEA.

SUDA'MINA, or **MILIARY ERUPTION**, is one of the diseases of the skin belonging to the class *vesiculæ*, or *vesicles*. The former name is derived from the fact, that the disorder is always accompanied with profuse sweating; while the latter has reference to the size of the vesicles, which do not exceed those of a millet-seed. The vesicles are most abundant on the neck and trunk, and are sometimes, but not always, attended with itching. They almost always occur in association with febrile disorders, which, however, do not seem in any way modified by these occurrences. The only known condition that favours their production is copious and prolonged sweating. They sometimes appear in health during the summer heat, when strong exercise has induced copious sweating. Pathologically, this disease is of so little importance that it is unnecessary to notice its treatment. It is, however, sometimes useful as a sign in diagnosis, especially in typhus and typhoid fevers.

SUDA'N, or **SOUDAN**, a vast tract of Central Africa, bounded on the N. by the Sahara; on the W. by Senegambia; on the S. by Upper Guinea, from which it is separated by the Kong Mountains; and on the E. by Kordofan. The Kong Mountains rise to the height of 3000 feet; while Mount Atlantika, near the sources of the Chadda, is 10,000 feet in height. The Niger (q. v.) waters the western regions, and in the east are Lakes Tchad and Fittri. The climate of the west and middle districts resembles that of Senegambia and Guinea; that of Eastern S. is still imperfectly known. Agriculture is pursued with considerable skill; cotton, tobacco, and indigo are abundantly grown; and wheat, rice, maize, Guinea-corn, and millet are among the ordinary crops. Gold-dust, which abounds in the rivers; iron, made from iron-stone, which prevails in all parts of the country; and ivory and feathers, are the principal exports. Of the numerous kingdoms and states into which the country is divided, the following are the chief: Bambara, Masina, Gando, Sókoto, Bornu, Bagirmi, Waday, and Dar-fur. The area is not known, but is generally estimated at 2,250,000 sq. m.; the pop. at from 10,000,000 to 50,000,000. S. has for many ages been the peculiar home of the negro race.

SU'DBURY, a municipal borough of Suffolk, 16 miles south of Bury St Edmunds, on the left bank of the Stour, across which a bridge connects the town with the suburb of Ballingdon in Essex, forming part of the borough. The silk and bunting manufactures are the most important branches of industry. There are also extensive brick-works, in which the white clay used is notable for its purity. Malting is extensively carried on. S. was one of the first towns into which the woollen manufacture was introduced by the Flemings. Pop. (1881) 6584.

SUDDEN DEATH may be induced by natural or by violent causes, and the detection of the true cause is obviously of very great importance, since the acquittal or conviction of a suspected person may depend upon it. Sudden death may occur naturally from syncope (fainting or swooning), from asphyxia (literally pulselessness), or, more correctly, apnæa (privation of breath), or from coma (insensibility). Syncope, or sudden cessation of the heart's action, may occur, as Dr C. J. B. Williams points out in his *Principles of Medicine*, in two ways. (1.) By the heart losing its irritability (or becoming paralysed), so that it ceases to contract; and (2.) By its being affected with tonic spasm, in which it remains rigidly contracted, losing its usual alternation of

relaxation. Sudden death from asphyxia, or, more correctly, from apnœa, occurs when, from any cause, the entrance of air into the lungs is prevented. It is not so often witnessed as a result of disease as of accident. It is sometimes caused by a spasmodic closure of the chink of the glottis (see LARYNX). Sudden death from coma is liable to occur in apoplexy and injuries of the head.

In all cases of sudden death, there is a strong tendency on the part of the public to suspect poisoning. It is very hard to make them understand that persons may die a natural death suddenly as well as slowly; or conversely, that death may really take place slowly, and yet be the result of poison. 'One of the means,' says Dr Taylor, 'recommended for distinguishing narcotic poisoning from apoplexy or disease of the heart, is the difference in the rapidity with which death takes place. Thus, apoplexy or disease of the heart may prove fatal either instantly or within an hour. The only poisons likely to operate with such fatal rapidity are prussic acid or nicotina. Poisoning by opium is commonly protracted for five or six hours. This poison has never been known to destroy life instantaneously or within a few minutes. Thus, then, it may happen that death will occur with such rapidity as to render it impossible, under the circumstances, to attribute it to narcotic poison.'—*Op. cit.*, p. 145.

In its relations to medicine and medical jurisprudence, the subject of this article has been fully discussed by Herrick and Popp, *Der plötzliche Tod aus inneren Ursachen*, 1848.

SU'DETENGEBI'RGE, the most important mountain-range of Germany, dividing Prussian Silesia and Lausitz from Bohemia and Moravia, and connecting the Carpathians with the mountains of Franconia. It does not form a continuous chain except in the middle, where it is known under the names of Riesengebirge (q. v.) and Isergebirge; the ends, both towards the north-west and south-east, broadening out into great rugged hilly plateaux, with broken chains and isolated peaks. The S. are composed chiefly of granite, gneiss, mica-schist, and porphyry, with superimposed beds of basalt and coal, and are clothed with pines to a height of between 2000 and 3000 feet. They are rich in minerals, especially in the metals, iron, lead, copper, zinc, tin, cobalt, with some silver and gold. Schneekoppe (Snow-Peak) in the Riesengebirge, about 5000 feet high, is the culminating point in the whole range.—The name S. is applied in a narrower sense to the south-east portion of the range, separating Silesia from Moravia.

SÛDRA is the name of the fourth caste of the Hindus. See CASTE.

SUE, MARIE-JOSEPH-EUGÈNE, a well-known French novelist, was born at Paris, 10th December 1804. His father, Jean-Joseph Sue, was one of the household physicians of Napoleon, and he educated his son for his own profession. At the age of twenty the young man became an army surgeon. In this capacity he served in the French expedition to Spain, under the Duke of Angoulême in 1823. Subsequently he transferred himself to the navy; and in 1828, was present at the battle of Navarino. In 1829 his father died, leaving him a handsome fortune, on the acquisition of which he ceased to practise his profession. After coquetting a little with art he betook himself seriously to literature, and very soon, in the department of fiction, he achieved a considerable popularity. His earlier efforts were sea-stories, somewhat after the manner of Cooper, or romances in imitation of Scott; and though in both fields he displayed talent, his true power was scarcely as yet developed. Something of it may, however, be traced in his *Mathilde, ou les Mémoires d'une Jeune Femme*, published in 1841; but it was first decisively made manifest in the famous *Mystères de Paris*, which began to appear the year after in the columns of the *Journal des Débats*. The furor of excitement occasioned by this work and its successor, *Le Juif Errant*, which appeared in the *Constitutionnel*, not only in France but elsewhere, has seldom, perhaps, been exceeded; and for both the writer received large sums of money. In 1846, his *Martin, l'Enfant Trouvé* was issued; in 1847—1848 appeared *Les Sept Péchées Capitaux;* and in 1852, he published *Les Mystères du Peuple*, his last work of any importance. Throughout Sue's later works there runs a vein of socialism; and at the revolution of 1848 he allied himself with the extremest sect of the Republicans. On 28th April 1850 he was elected deputy to the Legislative Assembly for the department of the Seine, and was assiduous in his duties as such till the *coup d'état* of December 1852, by which he was driven into exile. He retired to Savoy; and at Annecy he died 3d July 1857.

In the writings of Sue great power is displayed; but it is rather of the unhealthy kind, and depends for much of its effect on vicious sources of interest. His books are read once with a fever-heat of curiosity, and scarcely bear reperusal.

SUE'CA, a town of Spain, in Valencia, and 23 miles south of the city of that name, on the Jucar, about 4 miles from the Mediterranean. Brick and tile works are in operation, and there are several flour and rice mills. Pop. over 8000.

SU'ET is a variety of solid fatty tissue, which accumulates in considerable quantity about the kidneys, and the omentum of several domestic animals, especially the ox and sheep. Beef suet is extensively used in cookery, while purified mutton suet under the name of *Sevum Præparatum* occurs in the Pharmacopœia, and is obtained by melting and straining the internal abdominal fat. It consists of a mixture of the ordinary animal fats, with a great preponderance of the most solid of them; viz., stearin, which constitutes about three-fourths of the whole. The pure suet of the Pharmacopœia is 'white, soft, smooth, almost scentless; and is fusible at 103°.' It is used as an ingredient in cerates, plasters, and ointments. Ordinary melted suet is frequently employed in the same manner as lard, to preserve potted meats or fish and similar articles from the action of the air.

SUETO'NIUS, CAIUS TRANQUILLUS, son of Suetonius Lenis, a tribune of the 13th legion under Otho, was born probably a few years after the death of Nero. He is known to us chiefly as a Roman historian and miscellaneous writer, for his merits as which he is highly praised by the Younger Pliny. He was also, it is supposed, a teacher of grammar and rhetoric, and a composer of exercises in pleading; nay, from a letter of Pliny's to him, it may be gathered that he sometimes pleaded causes in person. Pliny procured him the dignity of military tribune, which, by S.'s desire, he got transferred to another. Though childless, S. was, through the same friendly agency, presented by Trajan with the *jus trium liberorum*, which, in that reign, was only to be had by great interest. He was afterwards secretary of the Emperor Adrian, whose favour he had secured. The date of his death is unknown. All his works (among which, as we learn from Suidas, there were several on topics usually treated by grammarians) have been lost, except his *Lives of the Cæsars*, his *Lives of Eminent Grammarians*, and (in part only) his *Lives of Eminent Rhetoricians*. It is by the first of these works

that he is most favourably known, replete as it is with information about the Twelve Cæsars, from C. Julius to Domitian, which is to be had nowhere else, and abounding with anecdotes which, while they too often prove the profligacy of his heroes, testify to the impartiality of their chronicler. From a period long before the renaissance to the present, these 'Lives' have always been favourite reading, and have found numerous editors, the best of whom is still Burmann (Amsterdam, 1736), and numerous translators into nearly every European language.

SUE'VI, first mentioned by Cæsar, in whose history (*De Bello Gallico*) the name is employed as the collective designation of a great number of Germanic peoples. They occupied a district of indefinite extent on the eastern side of the Rhine, and may have been the same tribes as those subsequently known as Chatti, Longobardi, &c. Cæsar states that their territory comprised 100 cantons, and was densely wooded, that they had towns (*oppida*), but no strongholds, and that every year a part of the population left their homes to seek employment in war. The S. of whom Tacitus speaks (*Germania*, 38, &c.) seem to have dwelt north and east of the S. of Cæsar, extending as far as the Elbe and the Baltic, which Tacitus calls the 'Suevic Sea.' The peoples united under the rule of Maroboduus, the Marcomannic chief, were Suevic, and hence the Marcomanni and Quadi, who figure in the reigns of Marcus Aurelius and Aurelian, are often called Suevi. After the name had fallen into disuse as a collective designation, it reappeared (second half of the 3d c., *Amm. Marc.*, &c.) as the name of a people occupying the same territory as the S. of Cæsar, who appear, however, to have been a mixed race made up of adventurers from different parts of Germany, and who probably took the name of S. after possessing themselves of the country. We find them in alliance with the Burgundians, Alemanni, Alani, Vandals, &c. They are among the most notable of the barbaric peoples that broke up the Roman Empire in the north-west and west. Bursting through the passes of the Pyrenees (409 A. D.), they, along with the Vandals, overran and wasted Spain (q. v.). Those who remained at home in Germany seem to have spread during the 5th c. east to the Neckar and the Rauhe Alps, and south as far as Switzerland. The medieval Swabians were their direct descendants.

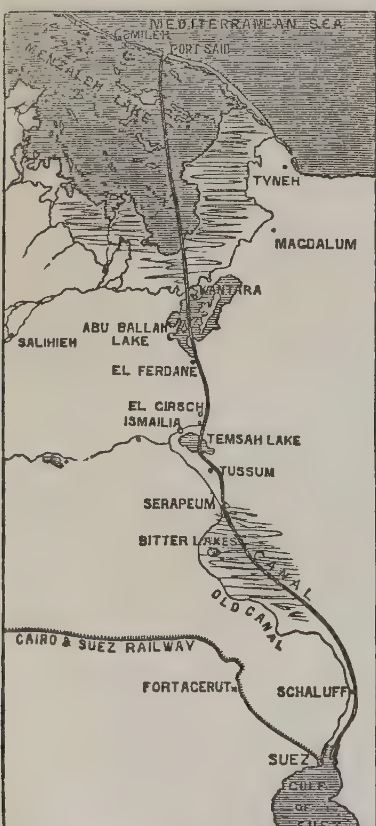
SU'EZ, until recently, a small, ill-built, wretched-looking town, on an angle of land near the northern extremity of the Gulf of Suez, 76 miles east of Cairo, with which it is connected by railway. Pop. variously estimated at from 1500 to 8000. It is walled on all sides but that towards the sea, has an indifferent harbour, but a tolerably good quay. S. of late has been greatly improved. English and French houses, offices, and warehouses have been erected in every direction, and the bazaars are assuming a respectable appearance. These bazaars are provided with clarified butter from Sinai, with fowls, grain, and vegetables from the Egyptian province of Sharkijeh, and with wood, dates, and cotton. Rain falls but seldom, sometimes not once in three years. All around stretches a burning waste of sands. S. owes its modern prosperity to the establishment of what is known as the *Overland Route* (q. v.) to India, in consequence of which a large portion of the traffic between England (and other European countries) and the East passes through the place. For a long time previous to the establishment of this route, S. had been in a state of complete decay, although, at a yet earlier period—previous, in fact, to the discovery of the sea-route to India by the Cape of Good Hope—it was a flourishing emporium of the products of East and West. The improvement that has recently taken place is partly owing to the works for the Suez Canal and the fresh-water canal carried to the town by the French, and partly to the enormous increase of traffic by the overland route.

The GULF OF SUEZ is the western and larger of the two branches into which the Red Sea divides towards its northern extremity, and washes on the west the coasts of Egypt, on the east those of the Sinaitic peninsula. Extreme length, 200 miles; average breadth, about 20 miles. The shores are sometimes low, barren, and sandy wastes, sometimes bold and rocky headlands.

The ISTHMUS OF SUEZ is a neck of land 72 miles in width at its narrowest part, extending from the Gulf of Suez on the south to the Mediterranean on the north, and connecting the continents of Asia and Africa. It embraces within its limits (according to the commonly received opinion) the fertile Goshen (q. v.) of antiquity; but it is now a wretched uninhabitable waste, consisting of mingled sand and sandstone, interrupted here and there with salt swamps or lakes, but almost entirely destitute of fresh water. The main interest, however, attaching to this region is a commercial one—viz., whether or not—since Egypt is on the great highway to India and China—it is practicable to cut a ship-canal through the isthmus. Without pronouncing positively on the point, we shall endeavour to give our readers a brief account of the state of the question.

It is certain that, in ancient times, a canal connecting (indirectly) the two seas did exist. At what period it was constructed is not so certain. Herodotus ascribes its projection and partial execution to Pharaoh Necho (about 600 years B.C.); Aristotle, Strabo, and Pliny less felicitously fix on the half-mythical Sesostris as its originator. The honour of its completion is assigned by some to Darius, king of Persia, by others to the Ptolemies. It began at about a mile and a half from Suez, and was carried in a north-westerly direction, through a remarkable series of natural depressions, to Bubastis, on the Pelusiac or eastern branch of the Nile. Its entire length was 92 miles (of which upwards of 60 were cut by human labour), its width from 108 to 165 feet, and its depth 15 (Pliny says 30) feet. How long it continued to be used, we cannot tell; but at length it became choked up with sand, was restored by Trajan early in the 2d c. A.D., but again became unusable from the same cause, and so remained till the conquest of Egypt by Amrou, the Arab general of the calif Omar, who caused it to be reopened, and named it the 'Canal of the Prince of the Faithful,' under which designation it continued to be employed for upwards of a century, but was finally blocked up by the unconquerable sands, 767 A.D. In this condition it has ever since remained. The attention of Europe was first turned to it in modern times during the invasion of Egypt by Bonaparte, who caused the isthmus to be surveyed by a body of engineers, who arrived at the opinion that the level of the Mediterranean is 30 feet below that of the Red Sea at S., an opinion which a subsequent survey proved to be erroneous. From this time, the question continued to be agitated at intervals, especially by the French, and various plans were proposed, but nothing definite was arrived at till 1847, when France, England, and Austria sent out a commission to measure accurately the levels of the two seas. The commissioners, M. Talabot, Mr Robert Stephenson, and Signor Nigrelli, ascertained that, instead of a difference of 30 feet, the two seas have *exactly the same mean level*. The only noticeable difference was, that there is a tide of 6½ feet at

the one end and 1½ feet at the other. Another examination leading to similar results was made in 1853. Mr Stephenson expressed himself very strongly against the feasibility of a canal, that is to say, a canal of such dimensions as would suit the requirements of modern commerce, and planned, instead, a railway from Cairo to S., which was opened (1858), and has since conveyed overland the British, Indian, and Australian mails. The French, however, were not satisfied with Mr Stephenson's conclusions, and M. Talabot, on his return to Europe, published in the *Revue des Deux Mondes* a plan for connecting the two seas by way of Alexandria and S. (or rather a point 6 miles below S.), for a description of which we have not space. In 1854, a new experimenter appeared in the person of M. de Lesseps, a member of the French diplomatic service in Egypt, who (1856) obtained from the pasha the 'concession,' i. e., the exclusive privilege, of forming a ship-canal from Tyneh (near the ruins of ancient Pelusium) to Suez. The peculiarity of M. de Lesseps's plan lay in this, that, instead of following an oblique course, and uniting his canal with the Nile, as the ancients had done, and as all the modern engineers had thought of doing, he proposed to cut a canal right through the isthmus in a straight line to Suez. This canal was to be 328 feet wide, and 100 miles



Map shewing Suez Canal.

long; the bottom to be 26½ feet under low-water mark, and 72.2 feet in breadth, and at each end there was to be a sluice-lock 328 feet long by 70 feet wide. By taking advantage of the tides at S., it was hoped that an additional depth of 3 or 4 feet might be obtained. But the colossal feature of M. de Lesseps's plan was the artificial harbours which he proposed to execute at the two ends, Tyneh and Suez. That at the Mediterranean end was to be carried out 5 miles in order to obtain a permanent depth of water for a ship drawing 23 feet, on account of the enormous quantity of mud-sand which the Nile annually pours out (30,000,000 cubic yards, it is said), and which the prevalent wind drives eastward along the shore towards the southern coast of Palestine. The quantity of stone required to construct this harbour has been calculated variously at from 3 to 12 million cubic yards, and there are no stone quarries except at a great distance from Tyneh! The pier at S. was to be carried out 3 miles, and in other respects the difficulties, though great, were not, as on the Mediterranean coast, *almost* insurmountable. The English, for political, perhaps, as well as for practical reasons, looked with aversion on M. de Lesseps's scheme; but in 1855, the question was again taken up in an international spirit, a new European commission was appointed, which reported that M. de Lesseps's scheme, somewhat modified, *was practicable*, and that a canal might profitably be constructed. The result of the report was the formation of a company, and after four years' work the canal, which has its Mediterranean entrance at Port Said, about the middle of the narrow neck of land between Lake Menzaleh and the sea, in the eastern part of the Delta, was completed. The canal was dredged through this lake, which runs far into the land directly towards S., and is connected with Lake Temsah, the Bitter Lakes, and other marshy swamps, and so with Suez. As early as December, 1864, the Mediterranean and the Red Sea had been connected. The communication, however, was not throughout by the permanent maritime canal, but simply by a fresh-water canal of no great width or depth. On the 18th of March, 1869, the waters of the Mediterranean were admitted into the Bitter Lakes with complete success, and in September a steamer made the passage along the entire length of the canal, and it was formally announced that the work would be opened on the 17th of November. The preliminaries commenced on the 15th, when the Emperor of Austria landed at Port Said. On the 16th the Empress Eugenie arrived, and on the 17th the French imperial yacht Aigle, followed by 40 vessels, anchored at Ismaïlia, having passed through the first part of the Suez canal in 8½ hours, and was here met by 4 steamers from Suez, the southern terminus of the canal; on the 19th of Nov. the fleet of steamers sailed for Suez, and on the 21st arrived at the Red Sea. The water was 20 feet deep at the shallowest part, and generally not less than 25 feet. The canal is open to vessels of all nations, and the transit can be made in 15 hours. It has cost about $60,000,000. From the day of its opening to June 30th, 1870, 7½ months, 393 ships had passed through the canal, 233 of which, with a tonnage of 195,428, paid £129,784 for tolls. For a description of the method by which the Suez canal was excavated, &c., see *Rep. of Commissioners to the Paris Exhibition*, vol. iv., by W. P. Blake, Washington, 1870. See also article SUEZ CANAL, in the *Supplement* to this work, in Vol. X.

SUFFOCA'TION. See ASPHYXIA and RESPIRATION.

SU'FFOLK, a maritime county of England bounded on the E. by the German Ocean, on the N. by Norfolk, and on the S. by Essex. Area 947,681 acres; pop. (1881) 356,863. The surface is for the most part flat, falling away into marshes on the north-west and north-east borders. The coastline, which is low and marshy, or lined with cliffs of shingle or gravel and red loam, is about 50 miles

in length, and is, on the whole, regular, being unbroken by any considerable indentation, and comprising no headland worthy of notice except Lowestoft Ness, the most easterly point in Great Britain. The tributaries of the Waveney, which separates S. from Norfolk on the north, and those of the Stour, which forms the boundary-line on the south, together with the river Lark, an affluent of the Great Ouse, and the Gipping, which, after it begins to broaden into an estuary, is called the Orwell, are the chief streams. The climate is cold in spring, but is drier than that of the western counties. The soil is of various kinds, some of which are very productive. 820,000 acres are under cultivation, and the most improved system of agriculture has been introduced, together with the best and newest agricultural implements. A polled breed of cattle, of which the cows are deservedly held in high esteem, is peculiar to the county. The S. pigs are a famous and most profitable breed. There are in the county about 500,000 head of sheep, chiefly Southdowns and crosses of this breed. The ordinary crops are raised. The county sends four members to parliament. Capital, Bury St Edmunds.

SU'FFRAGAN (Lat. *suffraganeus*, from *suffragium*, a suffrage or vote), the name given to a bishop in a province, in his relation of dependence or subordination to the archbishop, or rather metropolitan, of the province. See METROPOLITAN. In some continental churches, the name is applied to coadjutor-bishops appointed—as in the case of prince-bishops in the German Empire—to assist the bishop in his own diocese.

SU'FFRAGE (Lat. *suffragium*, derivation uncertain), a right to vote, and more particularly the right possessed by the citizen of a state where representative government exists, to vote for a member of the legislative body.

The idea that the universal enjoyment of political suffrage is a right by natural law, is grounded on the fiction, that the obligations of municipal law arise out of a social contract express or implied. In opposition to this notion, it is argued that the true purpose for which government exists is the general welfare of the nation; and it is the duty of the state to consider whether the suffrage may be more beneficially exercised by the many or the few. Infants, minors, idiots, and insane persons have everywhere been excluded from the suffrage, on the ground that sound judgment is necessary for its exercise. Persons convicted of crimes have been excluded, as a security to society; and also almost universally women, for reasons based on their relation to society and to the opposite sex. Like considerations of expediency, it is argued, are a ground for withholding the suffrage from those whose circumstances and station in life render it unlikely that they should form a sound judgment on political questions. It is the intelligence and enlightenment of the country that an elective legislature should represent; and in any large extension of the suffrage, there is obviously a risk of the intelligence of a constituency being swamped by its mere numerical majority. A widely extended suffrage has, however, been advocated as a valuable means of educating the people to self-dependence; and several philosophical politicians of the present day, who are favourable to a large extension of the electoral qualification, propose to obviate what they regard as its otherwise inevitable evils, by graduating the suffrage, so as to give each individual elector a number of votes corresponding as much as possible to his property, education, or social position. Schemes for this end, differing in detail, have been proposed by Mr J. Stuart Mill, in his *Considerations on Representative Government* (1861); and by Professor Lorimer in his *Political Progress not necessarily Democratic* (1857), and *Constitutionalism of the Future* (1865). See REFORM, REPRESENTATION, BALLOT.

SU'FISM (from *sufi* or *sofi*, the Greek *sophos*, a sage; erroneously also derived from Arab. *sof* or *suf*, wool, and thus designating an individual who wears nothing but woollen garments) designates a certain mystic system of philosophical theology within Islam. Its devotees form a kind of ecclesiastical order somewhat similar to that of the Fakirs (q. v.), or dervishes, but they are mostly of a far superior stamp; and some of the greatest Persian poets, philosophers, historians, and even kings belonged to their ranks. They assume four principal degrees of human perfection or sanctity. The first or lowest is that of the Shariat—i. e., of the strict obedience to all the ritual laws of Mohammedanism, such as prayer, fasting, pilgrimage, almsgiving, ablutions, &c., and the ethical precepts of honesty, love of truth, and the like. The second degree (Tarikat) is not attainable by all, but only by those higher minds that, while strictly adhering to the outward or ceremonial injunctions of religion, rise to an inward perception of the mental power and virtue necessary for the nearer approach to the divinity, the necessity of, and the yearning for, which they feel. The third (Hakikal = truth) is the degree of those who, by continuous contemplation and inner devotion, have risen to the true perception of the nature of the visible and the invisible—who, in fact, have recognised the Godhead, and through this knowledge of it have succeeded in establishing an ecstatic relation to it. This state is finally sublimated into that highest and last degree (Maarifal), in which man communicates directly with the Deity. Practically, the great mass of the people take the lowest degree; the second stage is reached by the 'Murides,' who do not fulfil the behests of the ceremonial law because they are behests, but because they are good in themselves, knowing that virtue is good; and because it leads to truth, they adhere to it for its own sake. They give alms because the sight of poverty grieves them; their ablutions are as much due to their desire of physical purity as to that of obeying a religious injunction. The third stage is that of the Naibs, to whom all this spiritualising of faith applies in a still more eminent degree. And the highest stage of attainable perfection is that of the Murshid, whose words are God's words, pure and simple, because he is in direct and constant communion with God. He is the 'Sun of faith,' by whose reflected light shine the Naibs, its 'moons.' All Sufistic poetry and parlance is to be taken allegorically and symbolically. They represent the highest things by human emblems and human passions; and religion being with them identical with love, erotic terminology is chiefly used to illustrate the relation of man to God. Thus the beloved one's curls indicate the mysteries of the Deity; sensuous pleasures, and chiefly intoxication, indicate the highest degree of divine love as ecstatic contemplation; while the wine-house, of which constant mention is made, merely indicates the state in consequence of which our human qualities merge in or are exalted into those of the Deity. Founded in the 9th c. by Kafi-Mullah, this peculiar mysticism has principally struck root in Persia, and chiefly among men of genius, e. g., Hafiz (q. v.). Recently, it has been revived, with slight modifications, by Shamil, the renowned and once formidable antagonist of the Russians, who undertook to enlist even the common soldiers, if not in the ranks of the

initiated—for Sufism, in its real meaning, is very exclusive—at least of its votaries; and the very lowest among them even had a sentence given him indicative of his forming part of the sect and of the gradations that form its main characteristics. In conclusion, it may be observed that Sufism mixes up all religions and all their prophets indiscriminately in one class; and the words idolatry, unbelief, licentiousness, and the like are generally used in their reverse sense by its votaries. Their principal religious writer is Jalaleddin Rumi (q. v.).

SUGAR (Lat. and Gr. *sacchar-*, Sans. *sarkara*, Pers. *schakar*, Arab. *sokkar* or *assokkar*, Sp. *azucar*, It. *zucchero*, Fr. *sucre*, Ger. *zucker*) is a general term applied by chemists to a number of neutral carbo-hydrates, possessing a more or less sweet taste, for the most part crystallisable, and produced by the vital processes going on in certain plants and animals. They are divisible into two groups, the first embracing such sugars as are capable of undergoing fermentation, and of being resolved, under the action of yeast, either directly or indirectly into alcohol and carbonic acid gas; and the second including those sugars which are not capable of being broken up by fermentation into the above-named products. The first group contains cane-sugar or sucrose, fructose or inverted sugar, trehalose, mycose, melezitose, melitose, grape-sugar or Glucose (q. v.), and milk-sugar or lactose; while the second group includes inosite or inosin, sorbite or sorbin, and scyllite or scyllin.

Cane-sugar or *saccharose* ($C_{12}H_{22}O_{11}$), the ordinary sugar of commerce, is by far the most important of this class of compounds; and in so far as its sweetening properties are concerned, it exceeds grape-sugar in the ratio of 5 to 2, and milk-sugar in a still higher ratio. It has a specific gravity of 1·6. It dissolves in about one-third of its own weight of cold water, producing a thick viscid syrup, and in all proportions in hot water; it is slightly soluble in absolute alcohol, but spirit of wine of specific gravity 0·830 dissolves about one-fourth of its weight. By the spontaneous evaporation of its watery solution, it is deposited in four-sided rhomboidal prisms. Common loaf-sugar and sugar-candy are two well-known forms of crystallised sugar; the former consisting of a mass of small transparent crystals, and owing its dazzling whiteness to the numerous reflections and refractions which the rays of light undergo within the interior from the numberless crystals of which it is composed; while the brown colour which the latter usually possesses is due to the colouring matter not having been removed from the syrup previous to crystallisation. The crystals of sugar-candy are larger than those of loaf-sugar, in consequence of the slower evaporation in the former case. When crystals of sugar—as, for example, two pieces of loaf-sugar—are rubbed together in the dark, a pale phosphorescent light is evolved. If a solution of sugar be boiled for a long time, it acquires an acid reaction, and loses its power of crystallising—a change which is attended by the assimilation of additional water, and the formation of the uncrystallisable inverted sugar which will be presently described. If the boiling be further prolonged, the inverted sugar ($C_6H_{12}O_6$) assimilates more water, and is converted into grape-sugar ($C_6H_{12}O_6 + 2Aq$), while a little formic acid and ulmin (a brown, nearly insoluble substance belonging to the *humus* group) are produced. The crystallisation of sugar is also prevented by the addition of a little oxalic, citric, malic, or any of the stronger acids to its solution; and in order to check the bad effects of an acid, a small quantity of lime is usually added to the cane-juice before it is heated.

The action of different degrees of heat on sugar has been carefully studied. At about 320°, sucrose fuses, and on cooling, forms the transparent amber-coloured solid known as *barley-sugar*, which, if kept for a long time, assumes a crystalline state, and becomes opaque. If the application of heat be continued until about 400°, the sugar loses two atoms of water, and *caramel*, which is described in the article GLUCOSE, is formed, and at a still higher temperature, the changes which sucrose undergoes are identical with those suffered by glucose. Sugar dissolves many metallic oxides when its solution is boiled with them—as, for example, freshly precipitated oxide of lead, lime, and baryta, and its presence prevents the precipitation of alkalies of various metallic oxides from their salts—the oxides of copper and of iron being thus retained in solution. Many metallic oxides are partially or entirely reduced when boiled with sugar; thus, chromic acid is reduced to sesquioxide of chromium, salts of the red oxide of mercury are converted into those of the suboxide, and salts of gold give a precipitate of the reduced metal. It does not reduce alkaline solutions of oxide of copper to the suboxide (Trommer's test) unless with the aid of heat, which converts it into glucose. Under the action of certain oxidising agents, it may be converted into propionic, formic, and acetic acids. Sucrose is not *directly* capable of undergoing fermentation; but in the presence of a ferment (yeast, for example) it is converted into glucose, and in that form it readily undergoes vinous, lactic, and butyric fermentation. Its action on polarised light is described below.

This variety of sugar is chiefly obtained from the juice of the sugar-cane, but it is also abundantly present in the juices of certain species of maple and of beet-root, all of which yield this substance as a commercial product; it is also contained in Sugar-grass (*Sorghum saccharatum*), whose juice yields 13 per cent. of sugar; in carrots and turnips, in the pumpkin, the chestnut, the young shoots of maize, in the flowering buds of the Cocos palm, and in a large number of tropical fruits. Its use as an article of diet has been already mentioned under DIET. Several articles of food contain some form of sugar in considerable quantity. In peas, there are 2 per cent. of sugar; in rye-meal and wheaten bread, about 3½ per cent.; in cows' milk, 4¾ per cent.; in goats' milk and in barley-meal, 5¼ per cent.; in human milk, in asses' milk, ripe gooseberries, and ripe pears, about 6 per cent.; in oatmeal, about 8 per cent.; in wheaten flour, from 4 to 8 per cent.; in beet-root, from 5 to 10 per cent.; in ripe peaches, 16½ per cent.; in ripe cherries, 18 per cent.; and in dried figs, upwards of 60 per cent. Although sugar is commonly regarded as a luxury, it is in reality a very valuable article of food (as, indeed, might be inferred from its presence in milk, and in both the yelk and white of eggs), since it is very rapidly digested, and supplies heat-forming or respiratory food to the system. 'When, however,' says Dr E. Smith, 'it is compared with wheaten flour, it is a very dear food, since three or four times more carbon will be obtained for 1*d.* in flour, besides nitrogen, none of which is found in sugar. It has also been proved by Messrs Lawes and Gilbert that even its fattening properties—that is to say, its power to form fat in the system, when it is supplied in excess of the quantity which the daily wants of the body require to produce heat—are not greater than those of starch as found in the cheapest grain.'—*Practical Dietary*, 1863, p. 63. In consequence of sugar being a fat-forming substance, it should be taken very sparingly in cases of excessive obesity. There are

certain forms of dyspepsia in which sugar should be avoided, as exciting increased gastric uneasiness; and in diabetes, all articles of food containing or (like starch) yielding sugar should be rigidly prohibited. Although prone to fermentation when in a diluted state, in its concentrated form sugar possesses great antiseptic power, and is extensively employed to preserve both vegetable and animal substances from decay. The sugar naturally existing in some fruits is often sufficient to insure their preservation in a dry state, while in other cases it is added, as in preserves and jellies. A mixture of salt and sugar applied to meat, fish, &c. preserves more of the natural flavour than mere salting does. Sugar converted into caramel is much used by cooks and confectioners as a colouring matter.

Closely allied in their chemical characters to sucrose are the following comparatively rare forms of sugar: (1) *Trehalose* ($C_{12}H_{22}O_{11} + 2Aq$), so called from *Trehala*, or Turkish Manna (the product of a coleopterous insect, *Larinus nidificans*), from which this variety of sugar is extracted, differs from sucrose in the following points—it crystallises in brilliant rectangular octahedra; contains water of crystallisation; fuses at 212°, and loses its water of crystallisation; is very soluble in hot alcohol; possesses about three times as great a rotatory power on polarised light; and when heated to 356° does not undergo further change. (2) *Mycose*, obtained from ergot of rye, possesses the same composition as trehalose, from which it mainly differs in crystallising in rhombic prisms, and in exhibiting a somewhat weaker rotatory power. (3) *Melezitose* ($C_{12}H_{22}O_{11}$), obtained from larch manna, differs from cane-sugar in its less sweet taste, and in exhibiting a less powerful rotatory action. (4) *Melitose* ($C_{12}H_{22}O_{12} + 3Aq$), the chief ingredient in the Australian manna yielded by the *Eucalyptus* tree, crystallises in acicular prisms, is feebly sweet, undergoes fermentation with yeast, but yields only half as much alcohol and carbonic acid as would be obtained from an equal weight of glucose, one half of this sugar being converted into an unfermentable syrupy body, known as *Eucalyn* ($C_6H_{12}O_6$).

More important than any of the above varieties, and differing from cane-sugar in a distinctive physical property, is the substance formerly known as *Fruit Sugar*, but now often described as *Inverted Cane-sugar*. The objection to the former name is, that the sugar contained in many ripe acidulous fruits, and formerly regarded as a distinct variety, is merely a mixture of dextrose ($C_6H_{12}O_6$) and lævulose ($C_6H_{12}O_6$), in equal proportions, which has already been noticed as resulting from the action of prolonged boiling, or of a little acid on cane-sugar. The same change occurs in many ripening fruits, in consequence of the presence of a peculiar albuminous ferment. Dextrose is not crystallisable, is soluble in dilute alcohol, and produces *right*-handed rotation; hence its name. By chemical means, cane-sugar is convertible into grape-sugar, a change which sometimes occurs spontaneously, as is seen in the gradual crystallisation of the sugar in dried fruits.

Grape-sugar, constituting the hard granular sweet masses occurring in old dried fruits, such as raisins, figs, &c., has already been described in the article GLUCOSE, or GLYCOSE, under which names it is commonly known to chemists. It is also known as *Starch-sugar*, because it is readily obtained by the action of a dilute acid on a hot solution of starch, and is identical with the sugar occurring in the urine in diabetes.

Milk-sugar, called also *Lactin* by Pasteur, and *Lactose* by Dumas, who has applied to it the formula $C_{12}H_{22}O_{11}$, is a purely animal product. It exists in considerable quantity in the milk, especially of the herbivorous animals, and is one of the most important and essential ingredients in that secretion. It may be obtained on a large scale by separating the curd from the milk, and evaporating the whey till it is ready to crystallise; when, on the introduction of small pieces of wood, the crystals of sugar are deposited on them. These crystals are four-sided prisms of a milk-white colour, and so hard that they crunch between the teeth. This variety of sugar is only moderately sweet (*vide supra*), requires about six times its weight of cold water for its solution, but dissolves readily in boiling water, while it is insoluble in alcohol or ether. If it be gradually heated to 284°, two equivalents of water are expelled, whereas, if it be suddenly heated to about 400°, all five equivalents are given off. When pure, milk-sugar is insusceptible of fermentation; but when boiled with dilute acids, it is converted into a directly fermentable sugar, in many respects very similar to grape-sugar, and to which some chemists have given the name of *Lactose*, a term commonly applied to milk-sugar itself. On treating a moderately diluted acid solution of milk-sugar with yeast, this variety is first formed, and then yields carbonic acid and alcohol; if, however, decomposing matters, as, for example, casein in the act of disintegration, are present, it undergoes lactic and butyric fermentation; and hence we understand how milk after exposure for a time to the air becomes sour. The intoxicating character of the drink prepared by the Kalmucks and Tartars from sour mares' milk, is due to this indirect vinous fermentation of sugar of milk. Regarding the uses of this variety of sugar, it may be observed that it is probably the most important of the constituents of whey (which is milk deprived of the whole of its casein except a mere trace held in solution), and hence that it is the active ingredient in the *whey-cure*, which is so popular in Switzerland. (The whey in these cases is usually obtained from goats' milk.) It is also the chief constituent of the globules used in homœopathy.

The second group of sugars, namely, those which are incapable either directly or indirectly of undergoing fermentation, are of less practical importance than cane-sugar, grape-sugar, or milk-sugar.

Inosin, or *Inosite* (derived from the Greek *is*, gen. *inos*, muscle), is represented by the formula $C_6H_{12}O_6$. It occurs as a normal constituent in the juice of the heart, and of the involuntary or unstriped muscles, and has also been found in the tissues of the lungs, spleen, liver, kidneys, and brain, and in the urine in Bright's disease and diabetes. It has been recently shewn that it is identical with the substance previously known as *Phaseo-mannite*, which is readily obtained from the unripe seeds of the common kidney-bean (*Phaseolus vulgaris*). It forms colourless efflorescent prisms, which lose four equivalents of water at about 210°. When mixed with decaying cheese and chalk, it becomes gradually converted into lactic and butyric acids. *Scyllite* is a saccharine matter closely resembling inosite, and occurring in various organs of several plagiostomous fishes, and especially in the kidneys of the rays and skate. It differs, however, from inosite in its crystalline form, and in its containing no water of crystallisation. Its composition is unknown. *Sorbin*, or *Sorbite* ($C_{12}H_6O_{12}$), derives its name from its occurring in the juice of the berries of *Sorbus aucuparia*, the Service Tree, and may be obtained in colourless transparent rhombic octahedra. It reduces oxide of copper to the suboxide (Trommer's test), and is of a sweetish taste.

Closely allied to the sugars, but differing from them in their chemical composition (inasmuch as they do not contain hydrogen and oxygen in the

proportions to form water), are *Mannite* ($C_6H_{14}O_6$), obtained from *Manna*, the inspissated juice of the *Fraxinus ornus*, but also occurring in celery, onions, asparagus shoots, *Laminaria saccharata* and other sea-weeds, certain fungi, the juice which exudes from apple and pear trees; *Dulcite* ($C_6H_{14}O_6$), the product of an unknown Madagascar tree; *Quercite* ($C_6H_{12}O_5$), obtained from acorns; and *Pinite* ($C_6H_{12}O_{10}$), from *Pinus lambertiana*, a tree growing in Australia and California. All these bodies are crystalline, and sweet to the taste.

Although chemists have hitherto looked upon the sugars as organic compounds, without any recognisable radical, and from their composition have termed them *carbo-hydrates*, 'the researches of Berthelot render it probable that the sugars as well as mannite, and the bodies allied to it, are polyatomic alcohols, like glycerine, for he has found that they possess the power of entering into combination with various acids, with elimination of water, in some cases yielding colligated acids analogous to the tannic, and in others furnishing neutral bodies closely allied to the fats.'—Miller's *Organic Chemistry*, 2d ed. p. 72.

Amongst the various chemical purposes to which the phenomenon of circular polarisation may be applied, we may especially mention its use in determining the quantity of any kind of sugar in solution. While some sugars give a right-handed rotation, others give a left-handed rotation, and each sugar exerts a definite amount of rotatory power. The following are the rotatory powers of the chief varieties of sugar, equal weights of each being dissolved in an equal bulk of water, and the temperature being 56°:

Cane-sugar	($C_{12}H_{22}O_{11}$),	right	73°·8
Trehalose	($C_{12}H_{22}O_{11}$),	"	199°
Melezitose	($C_{12}H_{22}O_{11}$),	"	102°.
Mycose	($C_{12}H_{22}O_{11}$),	"	193°
Dextrose	($C_{12}H_6O_{12}$),	"	56°
Lævulose	($C_{12}H_6O_{12}$),	left	106° at 14° 53° at 90°
Milk-sugar	($C_{12}H_{22}O_{11}$),	right	59°·3

For details regarding the apparatus to be employed, and the method of using it, we may refer to Miller's *Chemical Physics*, 3d ed. p. 204; and to a Memoir by Clerget in the *Ann. de Chimie*, iii., xxvi. 175. This method has been applied to determine the amount of sugar in diabetic urine, to ascertain the quantity of sugar which remains in the unfermented state in wines, and to other similar purposes. As, however, the process is one of extreme delicacy, the method must be used with great caution.

Manufacture.—The manufacture of sugar from the sugar-cane and other sources is now one of the largest branches of human industry, but this great development is of comparatively recent date; and although there are evidences of its very high antiquity in India and China, sugar appears only to have been vaguely known to the Greeks and Romans. It is mentioned by Theophrastus as 'honey in reeds;' and Lucan has the following line, which indicates a knowledge of its existence, but merely as a curious fact:

'Quique bibunt tenera dulces ab arundine succos.'

Its introduction to Europe appears to have been one of the results of the Crusades. The sugar-cane was grown in Cyprus about the middle of the 12th c.; it was from thence, at a later time, transplanted to Madeira, and at the commencement of the 16th c., was carried from the latter island to the West Indies. Originally, in all probability, only the sweet recent juice was known; for apparently the art of boiling it down, and forming it into raw sugar, was an invention of the 15th c.; and it was not until the middle of the following century that a Venetian discovered the art of refining sugar, which soon became established in Germany. The first refinery of which any notice exists was one in Dresden, as early as 1597; but long previous to this the subject had attracted so much attention as to be discussed in learned treatises one of which in particular, the *Saccharologia* of Sala, in the beginning of the 16th c., shews that the clarification of the syrup by defecation was then a matter of some importance. Still the manufacture of sugar in the countries to which it had been introduced made but slow progress, for its use was limited, by its dearness, to the wealthy. The material has now, however, become one of the commonest necessaries of life, 2,000,000 tons per annum being consumed. Until 1747, sugar was supposed to be the product of the sugar-cane only, but in that year, Marggraf, a German chemist, demonstrated that it was a natural product of other vegetables, and especially of the beet-root; and half a century later, its manufacture from that source was first commenced in Silesia. A large portion of the sugar consumed on the continent is now obtained from this source. See BEET-ROOT SUGAR.

Since we have become better acquainted with the sources of our own supplies, we have learned that a large portion of the raw sugar of the East Indies received in British ports as cane-sugar is in reality made from the juice of several palms, especially that of *Arenga saccharifera*, and the wild date, *Phœnix sylvestris*. The juice is obtained from these plants by cutting off the male spadix when young, and from the cut portion there is for four or five months a continual flow. The liquid is at first clear, and is immediately boiled down to a thick syrup, which granulates on cooling, and constitutes, if not otherwise purified, the coarse brown sugar called jaggery, which is extensively consumed in India. More carefully prepared, it is sent to Europe with sugar made in the cane-plantations, and is only distinguished from it by those well skilled in their respective qualities. If the juice is not immediately boiled, it becomes turbid, and passing into the vinous fermentation, forms the intoxicating drink called toddy.

In the British colonies of North America, and in the United States, very much sugar is made by boiling the juice or sap of the Sugar Maple-tree (*Acer saccharinum*). The *Sorghum saccharatum*, or Sugar-grass (see DURRA), is rapidly becoming of importance as a source of sugar both in North America and in the south of Europe.

Beet-root sugar is manufactured from the fresh-dug roots, chiefly of the varieties we call Mangold-wurzel. The process (which, however, is constantly undergoing modifications) is briefly described in the article BEET-ROOT SUGAR. Beet-root yields from 7 to 8 per cent. of sugar, of which only 3 to 4 per cent. are of the best quality, called *Melis*, 2 to 3 per cent. of the second quality, called *Farin*, and the remainder molasses.

The manufacture of starch-sugar is described in the article GLUCOSE.

From the beginning of the 16th c., when the sugar-cane of India was introduced to the West Indies, sugar has been one of the most important products of those islands. Careful cultivation has produced many varieties of this useful plant, some of which are better adapted than others for particular localities. The original variety introduced into the West Indies is still cultivated under the name of the *Creole Cane;* but the favourite variety is the *Otaheite Cane*, which is the most luxuriant grower, and gives the largest yield of

juice. It is the variety chiefly cultivated in Brazil, Demerara, and Venezuela, as well as the West Indies. In many parts of the East, another admirable variety is the *Batavian* or *Striped Cane;* it was originally raised in Java, and is the favourite with rum-distillers.

The extraction of juice from the sugar-cane is effected by simple pressure. In its native country, India, there are still in use in some districts

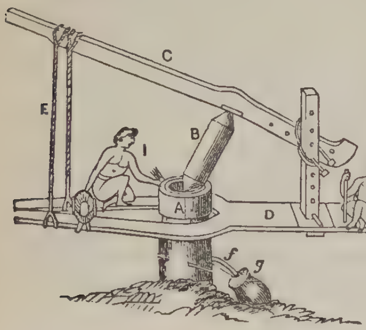


Fig. 1.

machines of the rudest construction, which are probably the same which were used a thousand years since. The Chinapatam Sugar-mill (fig. 1) consists of a mortar made by cutting down some hard-wood tree to within 2 or 3 feet of the ground, and hollowing the top of the portion left standing in the ground into the form of a mortar, A. A small hole is then bored obliquely through from the bottom of the cavity to the outside, and a pipe, *f*, conveys the juice into a jar, *g*. B is a cylindrical piece of wood, sharpened at each end, to act as a pestle, which is kept in its place with sufficient pressure by the lever C and the ropes at E. Two men are required: one at I has a basket supplied with small lengths of freshly-cut cane, which he places, two or three at a time, in the mortar, and, when necessary, removes the crushed ones; the other man sits on the other end of the train, balancing it, and at the same time drives oxen which are attached to the end of the beam D, and keep the movable parts of the mill constantly turning round. Notwithstanding the rudeness of this

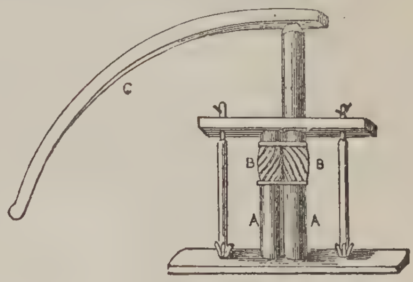

Fig. 2.

contrivance, very large quantities of sugar are made by it in India. A much better one, however, is the Chica Ballapura engine (fig. 2), which consists of

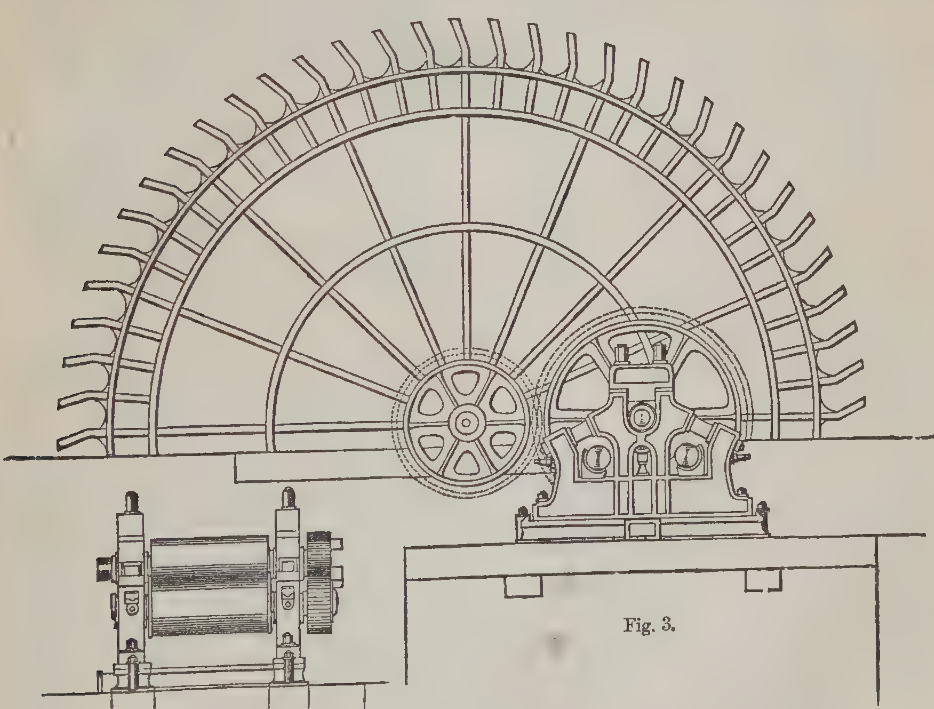

Fig. 3.

Fig. 4.

(Manufactured by W. and A. M'Onie, Glasgow.)

two upright rollers, A, A, the heads of which are formed into double spiral screws, B, B, which work in one another, so that when an ox is yoked to the long curved lever C, and goes round, one of the upright rollers, being connected with the lever, is made to revolve, and its screw carries the other

one round, but in an opposite direction. The pieces of cane are fed in by hand between the rollers, and as the juice is squeezed out, it flows down into a small hollow below the frame made to receive it, whence a small trough carries it to an earthen pot. The frame of this mill is securely fixed with stakes driven deep into the ground. In all probability, this very ancient machine has been the origin of all the most modern ones, for they all consist of rollers placed either vertically or horizontally, between which the canes are made to pass.

The mills now in general use for squeezing the juice out of the sugar-canes are very powerful machines. Fig. 3 represents an end view of a cane-mill, with the iron water-wheel and gearing for driving it, and fig. 4 represents a front view of the same mill. Some idea of the strength of those mills will be formed from the fact, that one of the rollers weighs upwards of 5 tons. The axles are 12 inches in diameter, and notwithstanding that they are made of the best wrought iron, they are not secure against breakage. The manufacture of sugar has probably been carried to greater perfection in the islands of Java, Mauritius, and Cuba than in any other parts of the world. In Java especially, in consequence of the great extent of the plantations, the planters have been able to erect very complete establishments for the manufacture of sugar.

The following very condensed account of the process of making sugar in Java will give some idea of the operation.

The canes, freed from all loose leaves, are passed through between the rollers under the greatest possible pressure that can be brought to bear upon them. The rollers revolve only from two to four times per minute. From 100 lbs. of canes, 65 to 75 lbs. of cane-juice will be expressed. This juice, which is of a sweetish taste, and of the colour of dirty water, passes direct from the mill to a small reservoir, where it usually receives a small dose of quicklime, and without delay runs off to large iron or copper vessels, heated either by a fire underneath or by steam-pipes in the liquid. As the temperature of the juice rises, a thick scum comes to the top, which is either removed by skimming, or the warm juice is drawn off from below the scum. The concentration of the juice is partly effected in a series of large open hemispherical iron pans about six to eight feet diameter, of which five or six are placed in a row, with a large fire under the one at the end. This one fire, which runs along under the whole row of pans, is found sufficient to make two or three of them nearest the fire boil violently, and in addition, it warms the juice in the pans furthest from the fire. As the juice first enters the pans furthest from the fire, it gets gradually heated, and the vegetable impurities rise in scum to the top, and are carefully removed. As the juice is ladled from one pan to the next, it boils with greater and greater vigour as it approaches nearer the fire, until in the pan immediately over the fire it seethes and foams with excessive violence; and this seems to be essential to the successful making of sugar. It is known that the presence of all those impurities which constitute the scum interferes with the crystallising of the sugar; and the rapid ascent of bubbles of steam through the liquid in the pans carries all impurities dispersed through the body of the liquid to the top, where they can be removed with facility. It is well known that great heat is very destructive to cane-juice; that is to say, it turns much of the crystallisable sugar into treacle or uncrystallisable sugar, but the gain arising from getting rid of much of the impurity in the cane-juice more than compensates for the destruction of part of the sugar. After the concentration has been carried to a given point, and all the scum has been got rid of, the application of a high heat, which would act with an increasingly destructive effect as the condensation becomes greater, is suspended, and the liquor, now of the colour of turbid port wine, and of the consistency of oil, is drawn into the vacuum-pan, where the concentration is completed at the lowest possible temperature, generally about 150° F. The vacuum-pan, shewn in fig. 5, is in universal use in all European sugar-refineries, and in all well-provided sugar-plantations. It is generally made of copper, of a spherical form, and from six to nine feet diameter. The bottom is double, leaving a space of an inch or two for the admission of steam between the two bottoms, and there is generally a long coiled copper pipe of three or four inches diameter above the inner bottom, so as to still further increase the amount of heating surface. This apparatus is made perfectly air and steam tight. Leading from its upper dome, A, there is a large pipe, B, communicating with a condenser, C, into which a rush of cold water is continually passing, so as to condense all the steam or vapour that arises from the liquid boiling in the vacuum-pan. The water which is constantly rushing into the condenser is as steadily withdrawn again by the pump at E. There is thus a constant vacuum in the pan, and, consequently, the liquid in it will boil at a much lower temperature than it would in an open pan or boiler. There is an extraordinary advantage in being able to effect

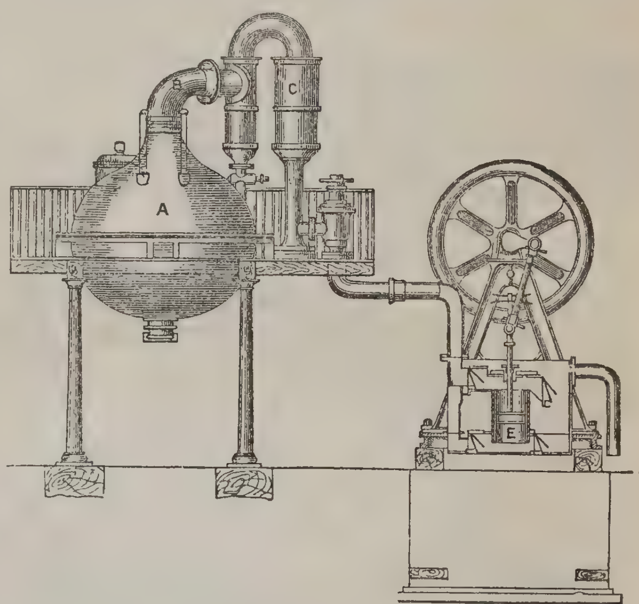

Fig. 5.—(Manufactured by W. and A. M'Onie.)

the later stages of the concentration at a low temperature, for it is when the liquid becomes thick that the destructive results of a high temperature become most excessive.

As the concentration of the liquid in the vacuum-pan proceeds, crystals of sugar begin to form, and the skill of the sugar-boiler is shewn by the uniformity of the crystals he produces. The boiling is commenced by filling in only about a third or fourth of the quantity the vacuum-pan will hold, and gradually adding more liquid as the crystals increase in size. The sugar-boiler is able to watch the changes going on in the vacuum-pan by means of small samples he withdraws from it by means of a suitable apparatus. The sugar-boiler holds those drops of thick fluid on his finger and thumb, between his eye and a strong light, and is thus able to detect those minute changes in its condition which shew that it is time to add an additional quantity. By the time the vacuum-pan is full, the contents have thickened, by the formation of crystals of sugar, into a mass of the consistency of thick gruel; it is then allowed to descend into a vessel called the heater, where it is simply kept warm until it can be run out into the 'forms,' which, in the sugar-growing colonies, are generally conical earthen pots, holding from one to two cwts. of sugar. It is allowed to cool and complete its crystallisation before the plugs, which close the bottom of the pots, are withdrawn. When this is done, from one-fourth to one-third of the contents of the form, which has remained in a fluid state, runs off into gutters leading to large tanks, from which it is again pumped up into the vacuum-pan, and reboiled, yielding a second quality of sugar. This reboiling of the drainings is repeated, with a continually decreasing result, both as to quantity and quality of the solid sugar obtained, and it is rarely carried beyond the fourth boiling. If the planter wishes to obtain Muscovada or unclayed sugar, the process is now complete, and the sugar is turned out of the forms, and packed for shipment. In some cases, the sugar is run direct from the vacuum-pans into casks or hogsheads, which replace the forms, holes being bored in the bottoms of the casks, to admit of the uncrystallised portion of the sugar draining out.

If *clayed* sugar is to be made, the forms are allowed to stand for a few days until all the treacle has drained out; and a quantity of thin mud, about the consistency of good thick cream, is then poured over the sugar, to the depth of one or two inches. The water contained in this thin mud slowly steals down through the sugar, and mixing with the coatings of treacle still adhering to the outsides of the crystals of sugar, renders them less viscid, and facilitates their descent to the bottom of the form. The mud remains, at the end of a few days, in the form of a dry hard cake on the top of the sugar, and none mixes with the sugar.

The process of claying sugar is simply washing off a coating of black or yellow treacle from a crystal of sugar, which is always white. This operation is possible without dissolving the crystal of sugar, simply because the treacle has a greater affinity for water than the crystallised sugar has. Anything that would yield a very slow and steady supply of water to the sugar, would do as well as mud or clay. There is always some loss of crystallised sugar in the process of claying, and attempts have been made to use strong alcohol for washing off the coatings of treacle from the crystals; but although alcohol dissolves treacle very freely, and scarcely acts on the crystals at all, still it has not been found to answer commercially. Besides the cost of the process, there is a difficulty in getting rid of the smell of alcohol in the sugar.

The centrifugal machine of Messrs Manlove, Alliott, & Co., has been very extensively used for getting rid of the treacle. Its action depends on precisely the same principle as that called into play when a sailor twirls a mop to expel the water from it. The centrifugal machine is simply a drum of 3 or 4 feet diameter, and 12 to 18 inches high, revolving at a great velocity on a vertical axis. The sugar, either direct from the vacuum-pan, or after it has been allowed to cool, is put, still mixed with the treacle, into the machine. As soon as the drum acquires a high velocity, its contents are forced by the centrifugal action against the drum, the cylindrical portion of which is made like a sieve, and admits of the escape of the treacle, but retains the crystals of sugar. Some idea of the efficiency of those machines may be formed when it is stated, that in a machine of three feet diameter, revolving at the usual speed of 1000 revolutions per minute, the tendency of the treacle to escape will be 514 times its own weight; that is to say, the treacle will have 514 times more force to fly off, than it has to drop off the crystal by the mere force of gravity.

Sugar-refining was unknown to the ancients, and even the refining previously referred to as having been established in Germany in the 16th c., consisted merely in clarifying the syrup, and producing a sort of sugar-candy; but one improvement followed another, until the process may now be considered as almost perfect. The chief difficulties attending the operation arise from the circumstance that the material to be operated upon is ever varying in quality. Not only is there a difference between the produce of two different plantations, but even the manufacture of the same plantation shews differences of quality; these differences arising chiefly from the presence of foreign substances, which seriously interfere with the operations of the refiner. The attempt made to test the exact quality of solutions of raw sugar by means of polarised light (see above) have hitherto been attended with little success in practice. Sugar-refining, as practised in Britain, has three distinct objects—(1) the production of loaves of thoroughly refined sugar; (2) crushed sugar; and (3) white sugar in separate crystals. The last is of comparatively recent introduction. In some existing sugar-refineries, old fashions still prevail; but our description must be confined to the most recent methods.

Sugar-refining is carried on in the United States on a great scale; Philadelphia, New York, and St Louis being the principal seats of the trade. The consumption of refined sugar has greatly increased, though some raw sugar is still used. Much of the dark-coloured sugar sold in the shops has passed through the hands of the refiners, and is simply inferior sugar, made out of the syrup which drains from the white loaf-sugar.

Sugar-refineries are built eight or nine stories high, and the raw sugar is first hoisted to the upper story, where it is dissolved in large tanks of hot water, care being taken to use as little water as possible for the purpose. A quantity of bullock's blood is stirred into the solution of sugar, and the heat being gradually raised, the albumen of the blood coagulates, and rises to the surface in the form of a thick light scum, bringing with it nearly all the mechanical impurities floating in the fluid. The liquor, still hot, is then passed into the bag-filters shewn in fig. 6. Those filters are made of a very closely woven cotton cloth, capable of retaining the minutest mechanical impurity. In order to facilitate the passage of the liquor through the bags, they are suspended in a kind of iron closet, and surrounded by an atmosphere of steam to keep the liquor hot. From the bag-filters, the liquor, now freed from all mechanical impurities, but of a

dark colour, flows into a lofty cylindrical iron filter, of about 5 or 6 feet diameter, and 20 or 30 feet high, filled with animal charcoal, that is, charcoal made of bones. This charcoal is reduced to coarse powder; and the dark offensive liquor is allowed to percolate very slowly through the mass. The result is, that it flows out at the bottom a perfectly transparent and pure solution of sugar. The charcoal can only be used for a few days at a time, because it gradually loses its purifying power; when the liquor begins to flow through it without being purified, it is taken out of the filter, and reburned, which completely revives its powers.

Fig. 6.

The liquor as it flows from the charcoal filter is a mixture of pure sugar and pure water, and perfectly transparent. The application of heat is the only mode of expelling the water, and this unfortunately blackens the sugar again. In order to get rid of the water with as little heat as possible, the colourless liquor is boiled in the vacuum-pan as in the early process of the manufacture (see fig. 5). The liquor boils in vacuo at about 150° F., and even this moderate heat has the effect of turning it quite brown. When it has been sufficiently concentrated by boiling in the vacuum-pan, which takes from 1¼ to 2½ hours, it is run into the sugar-loaf forms (fig. 7); which, after cooling, are carried to a room kept warm by means of steam-pipes. This warmth facilitates the flow of the treacle or syrup out at the aperture seen at the bottom of the form. To get rid of the coating of coloured treacle which still hangs about the crystals of sugar, a small quantity of a saturated solution of pure white sugar is poured on the top of the form. This strong liquor is unable to dissolve any more sugar, but being more fluid than the sticky coatings of treacle or syrup adhering to the crystals, it mixes with the coatings, and makes them fluid enough to flow down to the bottom of the form, leaving the crystals clear of syrup or treacle, and consequently free of all colour. This process of washing off the colouring matter from the crystals of sugar is the same in principle as the 'claying' used in the production of sugar. The loaves of sugar, after standing some time, to admit of all the liquor draining off, are wrapped in paper, and dried in stoves heated by steam. The liquor draining from the forms is reboiled in the vacuum-pan, and forms loaves of an inferior quality; and the liquor draining from the inferior loaves is again boiled into the yellow sugars known amongst sugar-refiners as bastards.

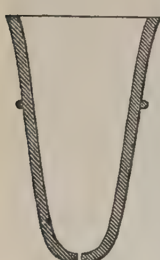

Fig. 7.

Crushed or Crashed Sugar is simply inferior loaves crushed while still soft and moist, and packed in hogsheads, instead of being left in the loaf form.

The syrup which drains from refined sugar is reboiled, and constitutes the *Golden Syrup* of the shops.

Crystal Sugar.—In making the sugar crystals, all the processes are carried on as in refining, until the syrup is clarified. Then it is boiled or concentrated in a vacuum-pan of larger size than ordinary, and the concentration is carried on until minute crystals appear. Fresh syrup is then added from time to time, great care and experience being required to insure a regular feeding of the first-formed crystals, and prevent the formation of a second crop. When the crystals are large enough, the contents of the pan are transferred to the centrifugal machines, which quickly separate the crystals in a perfectly dry state from the uncrystallisable syrup. The crystals are of a square tabular form, with a deep groove across in one direction, dividing the crystal into equal parts as in fig. 8. This kind of sugar is much liked for coffee, &c., but the crystals dissolve with difficulty.

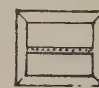

Fig. 8.

Louisiana is the chief seat of sugar production from the sugar-cane in the United States. The total number of sugar-growers in 1868 was 747, with 573 sugar-houses in operation. The total production of sugar in Louisiana has been stated to have been, in 1864, 6668 hhds.; in 1865, 15,500; in 1866, 41,000; in 1867, 37,647; in 1868, 84,256; and in 1869, 87,090 hhds. The quantity imported into the United States in 1870 amounted to 591,576 tons of sugar, 16,000 tons of melada, and 47,768,267 gallons of molasses: total value, $41,650,000. Into Great Britain, in 1869, 551,687 tons of raw sugar and 47,586 tons of molasses were imported; total value, £14,143,527.

SUGAR-CANE (*Saccharum*), a genus of grasses, natives of tropical and sub-tropical countries. The Common S. (*S. officinarum*) is originally a native of

Sugar-cane (*Saccharum officinarum*).

the East Indies, was brought to the south of Europe by the crusaders, and in the 15th and 16th centuries found its way into all the European colonies within the tropics. In Europe the cultivation of the S. has always been very limited, and is scarcely practised except in Sicily and Andalucia. In China, it extends to 30° N. lat., and in North America to 32°; in the southern hemisphere only to 22° S. lat. The plant

is a perennial, with a creeping root, sending up a number of culms or stems generally 8—12 feet high, which have many joints, are of various colours, and about 1—2 inches thick. They are filled for about two-thirds of their length with a loose, sweet, juicy pith. The leaves are ribbon-shaped, and 4—5 feet long, with a strong whitish middle nerve. The flowers are in great diffuse pyramidal panicles of a yard in length.—The Violet-coloured S. (*S. violaceum*) is particularly esteemed, and much cultivated in the West Indies.—The Chinese S. (*S. Sinense*), cultivated in China, has the stem in great part covered with the sheaths of the leaves. Cultivation has produced many varieties of these species; if, indeed, they are originally distinct species, and not themselves mere varieties.—The species of *Saccharum* are numerous; they contain much silica in the rind, and some of them are much employed in India for thatching and for making mats, as well as for screens and light fences. The Bengalese make their pens of the hollow stems of *S. semidecumbens* and *S. fuscum*.

The S. is usually propagated by cuttings. For this purpose the top joints are used. The cuttings are planted in rows three or four feet apart, and at intervals of about two feet in the rows. The largest varieties, in rich moist soils, attain a height of 20 feet; but in dry poor soils, the height is sometimes scarcely more than 6 feet. The plant *tillers* like wheat, but not to the same degree. The cane-ground is kept clean by hand-hoeing, or by the plough. Hand-hoeing was formerly universal in the West Indies, but the plough is now very generally used where the nature of the ground permits. The best varieties are ready for cutting in about ten months from the time of planting, but other varieties require a longer period of growth, from 12 to 20 months. When the canes are fully ripe, they are cut a little above the ground, and tied in bundles to be conveyed to the mill. Fresh canes, called *rattoons*, spring from the root, so that the plantation does not require to be renewed for several years; but the canes of the first crop are the largest, and a gradual decrease of size takes place. The ordinary practice on sugar estates is to renew a part of the plantation every year.

The name CHINESE SUGAR-CANE is sometimes given to the SHALOO or SUGAR-GRASS, already noticed in the article DURRA. Its cultivation in America has extended as far north as Maine. The sugar obtained from it is equal in quality to that from the true S., and the quantity is very remunerative. In Illinois, a grower procured 384 gallons of syrup per acre, which he sold to the sugar-refiners at one dollar a gallon. The whole quantity of syrup now produced from this grass in the United States is estimated as exceeding 15,000,000 gallons. Its cultivation is rapidly extending, particularly in the north-western states. The state in which at present it is most extensively cultivated is Ohio. The manufacture of sugar from it is partly carried on in large works, but chiefly on small scale, by the farmers themselves. The processes are very similar to those adopted for the sugar-cane. The plant was unknown in America till 1857. Numerous varieties are already in cultivation; one class of them, called *Sorgo*, being derived from Chinese seed; another, called *Imphee*, from seed which was brought from Africa. Deep ploughing is of great importance in preparing the land for the sugar-grass. Rich land is best suited for it, and well-rotted manure is of great use. The seed is sown in spring, as soon as the winter frost has passed away, in rows 4 feet apart, and the plants are thinned out to 12 or 18 inches. The crop is cut rather before the seed is mature. If not touched by frost before being cut, it may be kept a long time without injury. A frost which merely kills the blades, and does not freeze the stalk, does no considerable harm.

SUGAR-OF-LEAD, the common name for Acetate of Lead. See LEAD.

SUHL, a town of Prussia, province of Saxony, and government of Erfurt, is situated on a small stream, called the Lauter, in a romantic valley on the south-west side of the Thuringian Forest, 32 miles south-south-west of Erfurt. The name S., which in the Sorb-Wendish dialect means salt, is probably derived from the salt springs, formerly much worked. Mining is extensively carried on in the neighbourhood, and has been so for centuries. The principal manufactures are iron and steel wares, chemical preparations, paper, and leather. S., celebrated in the days of chivalry as the 'Arsenal of Germany,' still maintains its ancient reputation as a manufactory of arms. Pop. 8987.—Its history is very interesting; see Werther's *Sieben Bücher der Chronik der Stadt Suhl* (2 vols. Suhl, 1846—1847).

SUHM, PETER FRIDERIK, a Danish historian, was born in Copenhagen, 18th October 1728, of an ancient and noble family, and was sent to the university of Copenhagen, where he graduated in law in 1748. A few years later, he went to Norway, for the sake of prosecuting his studies in philology and history, in conjunction with the learned historian Schöning, and did not return till 1765 to Copenhagen, where he continued to reside till his death in 1798. Among his numerous works on the early mythical and political history of Denmark we may instance the following: *Forsoeg til Forbedringer i den gamle danske og norske Historie* (1757); *Om de nordiske Folks ældste Oprindelse* (1770); *Om Odin og den hedenske Gudelære* (1771); *Critisk Historie af Danmark i den hedenske Tid*, i.—iv. Band (1774—1781); *Historie af Danmark*, 1*ste Tome* (1782). Besides numerous other historical essays, moral treatises, poetic compositions, contributions to the philosophical and literary periodicals of Germany, France, and Denmark, &c., he edited *Scriptores Rerum Danicarum Medii Ævi*, from vol. iv. to vol. vii. inclusive (Hafniæ, 1776—1792), and took upon himself the cost and supervision of the publication of many remains of old northern literature. S. was an indefatigable collector of rare and curious books; and in 1796, in return for a pension from the government, he made over to the Royal Library of Copenhagen his valuable library of 100,000 volumes, to which he had previously allowed the public access. After the death of his only son, he devoted the greater part of his ample means to the purpose of having copies made of the more valuable MSS. in the collection, many of which were, moreover, printed at his sole charge; besides which, he founded scholarships, and afforded direct pecuniary assistance to many poor students and learned men. He died in 1798. S.'s collective writings were brought out by S. Poulsen, in 16 vols., between 1788—1799; and various editions of his lesser works have at different times appeared in Germany, as well as in Denmark, where he is justly regarded as one of the most learned and laborious and patriotic writers of his country.

SU'ICIDE (Lat. self-murder) is a heinous crime, by the law of the United Kingdom, though it was treated as venial by the Roman law, and was the subject of panegyric by Stoic philosophers. The law of England treats it as a felony, and hence there may be accessories to it, so that if A persuade B to kill himself, and B does so, A is guilty of murder. The term **suicide**, or *felo de se*, not only

includes one who deliberately kills himself, but also one who in maliciously attempting to kill another is himself killed. If A, however, requests B to kill him, and B does so, A is not a *felo de se*, though B is a murderer. If A and B mutually agree to commit suicide together, and in the attempt one only dies, the other is guilty of murder. When it is said that a man was a suicide, this implies that he was in his senses, for otherwise he committed no crime; hence an insane person, unless when in a lucid interval, cannot commit the crime. The punishment inflicted on a suicide consisted, formerly, in an ignominious burial in the highway, with a stake driven through the body, and without Christian rites; also the legal consequence was forfeiture of the goods and chattels to the crown. The only consequences now are forfeiture of goods, and deprivation of Christian rites. The burial now takes place in a churchyard, but between 9 and 12 P.M. An attempt to commit suicide is not punishable like an attempt to murder a third party, nevertheless it is a misdemeanour. The consequences of suicide on the contract of life-assurance are generally guarded against by an express stipulation, that if the assured die by his own hand, the policy shall be void; and it has been held by the courts that the policy is forfeited even though the party destroyed himself in a fit of frenzy or delirium.—In Scotland, suicide is also followed by forfeiture of the movable estate to the crown.

There are, no doubt, even in modern times, some who hold the theoretical opinion that suicide is permissible in certain circumstances; but in regard to those who have actually committed or attempted the crime, there has almost always been detectable evidence of cerebral changes; or, at all events, of that irritation and excitement which initiate and accompany molecular disorganisation of the nervous structure. In short, suicide, as a rule, is a symptom of some form of insanity, permanent or temporary, in which the emotions and passions are excited or perverted. Suicide is likewise a concomitant of certain bodily diseases; for example, of dilatation and fatty degeneration of the heart, of blood-degeneration, of affections of the intestinal mucous membrane, of the uterus, and of the brain and nervous matter; and it may be regarded as a frequent sequence of the melancholic, the morose, and hypochondriacal temperament. It has appeared as an epidemic; it has been observed as a hereditary tendency in certain families; and as a tendency more frequently exhibited by males than females; more frequently by the educated and affluent than by the industrial and ignorant classes; most frequently in large cities; and as directly engendered by luxury, political agitation, gambling, intemperance, and demoralisation. It would appear, however, that indulgence and asceticism, riches and extreme poverty, claim nearly an equal number of victims. It has been calculated that twice as many artisans commit suicide as labourers. In 1840, it was found that in every 10,000 of the population, 1·33 masons, carpenters, butchers, 7·43 tailors, shoemakers, bakers; 4·9 bankers, professionals; 2·0 of persons assured in Equitable Office; 7·8 dragoons; 6·7 servants and coachmen; 4·0 paupers, died by their own hand. Observation has shewn that from 20 to 35 is the most influential age in inducing the suicidal tendency; and the age appears to determine, to a certain degree, the modes of death selected as well as the proclivity. As might be expected, the nature of the delusion, the accessibility of the means, imitation, the profession or pursuit of the individual, novelty, and notoriety, all influence the choice of the instrument or means of death. The theomaniac dies by crucifixion; the great majority by ropes, rivers, wells, razors, arsenic; the medical man by aconite, chloroform. Even sex is characterised by peculiar preferences. Females seek voluntary death according to the following order of the means—hanging or strangulation, abstinence, precipitation, drowning, cutting, poison; males, again, according to this order—cutting, shooting, hanging, poison, drowning. Race, climate, country, and the distinguishing polity of different societies to a certain extent affect the proportion of suicides to the population. In the kingdom of Sweden, there is calculated to be one suicide to every 92,375 inhabitants; in Saxony, 1 to 8446; in Russia, 1 to 34,246; in the United States, 1 to 15,000. In Paris, 1 suicide occurs in 2700; in St Petersburg and London, 1 in 21,000 citizens. Middlesex, again, is the most prolific of all English counties; Chester least so: there being in the former, 10·5, in the latter, 7·2 to 100,000 people. In all England, the proportion is 7·4.—*Anatomy of Suicide*, Forbes Winslow; *Du Suicide et de la Folie Suicide, &c.*, à Brièrre de Boismont; *Traité du Suicide*, Louis Bertrand; *English Suicide Fields*, Radcliffe, p. 701; *Medical Critic*, 1862.

SU′IDÆ, a family of Mammalia, of the order *Artiodactyla*, division *Omnivora*, having the feet generally four-toed, the hinder feet sometimes three-toed; the toes hoofed, the two front toes forming the principal part of the foot, the others smaller and scarcely touching the ground; the snout abruptly truncated, mobile, muscular, and sensitive, but not elongated into a proboscis; the incisor teeth variable in number, the lower ones all directed forwards, the canines projecting, and bent upwards; the stomach little divided. To this family belong hogs, wart-hogs, peccaries, &c., and many extinct types.

SUIDAS, the name given to the compiler of a *Lexicon* some time during the Byzantine Empire. When he lived, or who he was, or whether he was even called S., no one can say; but it is customary to place him about the 10th or 11th century. The *Lexicon* bears unmistakable evidence of having gone through many hands; and though we can fix the date when several of the articles *must* have been written, it is impossible to ascertain whether they are the composition of the first compiler or of a later editor. The work is a sort of cyclopædia, giving an explanation of words, and notices of persons, places, &c., in alphabetical order. It is utterly destitute of literary or critical merit, but is valuable in the eyes of scholars on account of its numerous extracts from ancient Greek writers, grammarians, scholiasts, and lexicographers, whose writings in many cases have perished. The first edition appeared at Milan (1499); since then, the best editions have been those of Küster (Camb. 3 vols. 1705), Gaisford (Oxf. 3 vols. 1834), and Bernhardy (Halle, 2 vols. 1834).

SU′I JU′RIS, in the Roman law, the condition of a person not subject to the *Patria Potestas* (q. v.). The paterfamilias was the only member of a family who was *sui juris*, all the rest being *alieni juris*, including sons, unmarried daughters, the wife, and the wives and children of the sons of the paterfamilias. A daughter, on her marriage, passed into the family of her husband; but a son did not become *sui juris* by marriage. A son or unmarried daughter became *sui juris* on the death of the paterfamilias. In his father's lifetime, a son could only become *sui juris* by emancipation. The laws of the Twelve Tables declared that a son three times sold by his father should be freed from his power; and the ceremony of emancipation was of the nature of a fictitious sale gone through three times, in order to liberate

the son from parental control. *Connubium* being the foundation of the *patria potestas*, a bastard was *sui juris*.

SUIR, a river of Ireland, rising in the north of the county of Tipperary, flows south through that county by the towns of Thurles and Cahir. Ten miles south of Cahir it bends eastward, forming the boundary of Tipperary and Waterford, and passing by Clonmel and Carrick. It then passes out of Tipperary, and meeting the Barrow at Passage, Waterford, falls into the sea in Waterford Haven, after a course of about 100 miles. It is navigable by barges as far as Clonmel.

SUIT IN CHANCERY (British) is the process corresponding to an action in a court of law. The suit generally commences with a bill, i. e., a petition to the Lord Chancellor, which sets forth the grievance, with a prayer for redress. It is signed by counsel, and is served on the defendants, either personally or at the dwelling-place. They must then enter appearance, and put in either an answer or a demurrer, or a plea, which are the several defences to the suit according to the nature of the subject-matter. After the hearing, which takes place before a Vice-chancellor or the Master of the Rolls, a decree is pronounced, which may be appealed to the Lord Chancellor or Lords-justices, and finally to the House of Lords.

SUL, Rio Grande do. See Rio Grande do Sul.

SULIMA'N MOUNTAINS, a mountain range upwards of 350 miles in length, running from north to south, and forming the boundary between Afghanistan and the Punjab. In lat. about 33° 20′, it throws off the lateral branch of the Salt Range (q. v.). The highest summit of the range is Tacht-i-Suliman (Solomon's Throne), 11,000 feet high, and covered with snow for three months of each year.

SULI'NA, one of the lower branches of the Danube (q. v.), flows through the middle region of the delta of the great river, and enters the sea at about the same distance from the Kilia mouth on the north and St George's mouth on the south. It is the smallest outlet of the Danube, and conveys only $\frac{2}{27}$ths of the main river to the sea; but its channel through the bar that lines the coast is deeper than that of the other mouths, and therefore the S. is more frequented by vessels than any other branch of the Danube.

SU'LIOTS, a people in and around the valley of Acheron, the southern corner of the pashalik of Janina (*Epirus*) in European Turkey, are a mixed race, being partly of Hellenic and partly of Albanian origin. They are the descendants of a number of families who fled from their Turkish oppressors to the mountains of Suli (whence they derive their name) during the 17th century. In this obscure corner of the Turkish Empire they prospered, and towards the close of the 18th c., numbered 560 families, inhabiting 90 hamlets. For about 15 years they heroically resisted the encroachments of Ali Pasha (q. v.) of Janina upon their independence, the very women taking part in the strife. Vanquished in 1803, they retreated to Parga, and afterwards to the Ionian Islands, where they remained till 1820, when their old oppressor, Ali Pasha, finding himself hard pressed by the Turks, invoked their aid, offering them guarantees for his faith, and his grandson as a hostage. Eager to return to their cherished home, they accepted these terms, and under Marcos Bozzaris (q. v.), maintained a long and desperate conflict with the Turks, but were ultimately forced again to flee from their country, and take refuge to the number of 3000 in Cephalonia, though a large remnant preferred to skulk in the neighbouring mountains. Though, after this, they took an active and glorious part in the war of Greek independence, their country was not included by the treaty of 1829 within the Greek boundary-line; but many of them, as Bozzaris (son of Marcos) and Tzavellas, have since been raised to important political offices in the new kingdom of Greece.—See Perrhaebos's *History of Suli and Parga*, an interesting work, in the modern Greek language (2d ed., Venice, 1815), translated into English (Lond. 1823); and Lüdemann's *Wars and Ballads of the Suliots* (Leip. 1825)

SU'LLA, L. Cornelius, surnamed by himself Felix, the ablest Roman after the younger Scipio until the appearance of Julius Cæsar, was born 138 B. C. His family was a member, but not a distinguished one, of the Cornelian *gens*, or 'clan.' In 107 B. C., he was elected quæstor, and sent to Africa with the cavalry that the consul Marius (q. v.) required for prosecuting the Jugurthine War. He rapidly acquired a brilliant reputation as an officer, and crowned a series of important services by inducing Bocchus, the Mauritanian king, to surrender Jugurtha, whom he brought in chains to the Roman camp (106 B. C.). Marius was not over well pleased at the distinction achieved by his subordinate. In the campaigns that followed (104—101 B. C.) against the Cimbri and Teutones, S.'s reputation continued to rise, although Marius was still regarded (and with justice) as the first general of the state. For several years after the destruction of the barbarians, S. lived quietly, taking no part in public affairs; but in 93 B. C. he stood for the prætorship, and won it by a liberal distribution of money among the people. Next year, he was sent to Cilicia as proprætor, to replace Ariobarzanes on the throne of Cappadocia, from which he had been driven by Mithridates. On his return to Italy (91 B. C.), the long-smouldering animosity between Marius and him was on the point of bursting forth, but the terrible *Social War* forced all Romans to postpone their quarrels until the common danger had been averted. Both Marius and Sulla commanded armies in this great struggle; but the successes of S. threw those of Marius into the shade, and the mortification of his rival was deep and bitter. In 88 B. C., S. was elected consul along with Q. Pompeius Rufus, and the senate conferred on him the command of the Mithridatic War. But this was a command that Marius himself passionately desired, and when he heard that S. had obtained it, he rushed headlong into treason and civil war.

Here it may perhaps be necessary to observe that Marius and S. were not only personal rivals, but the leaders of opposite political parties. The former, a man of humble origin (see Marius), was a rough, stubborn, irascible, and illiterate *plebeian;* the latter, a finely cultivated *patrician*, subtle and sagacious in policy, and winning in manners. In the terrible scenes that ensued, although S. shewed himself by far the fiercer and more sanguinary of the two, it should not be forgotten that it was Marius who commenced the contest. Allying himself with the tribune P. Sulpicius Rufus, a political adventurer in difficulties, Marius placed himself at the head of the new Italian party, on which the rights of Roman citizenship had been conferred, and hoped to force the senate to recall the appointment of S. to the command of the expedition to the East. S. was compelled to flee to Nola in Campania, where his camp then was; but finding the soldiers full of enthusiasm, he resolved to lead them against the pseudo-government that had been established at Rome. The story of the overthrow of the Marian party, the expulsion of Marius, and his subsequent wanderings in Africa, &c. are well known, and intimately as these events

are inwoven with the fortunes of S., cannot be repeated here. Suffice it to say, that after settling affairs at Rome as well as he could, S. embarked for the East (87 B. C.), and was away for four years. Most of his fighting, however, was done in Greece against Archelaus, an ally of Mithridates, whom the latter repeatedly subsidised with men and money. Athens was stormed and plundered (86 B. C.), and Archelaus himself was defeated with frightful slaughter at Chæroneia in the same year, and again in the neighbourhood of Orchomenos (84 B. C.). S. now crossed the Hellespont, crushed Fimbria, a general sent out by the Marian party (which, in S.'s absence, had again got the upper hand in Italy), forced Mithridates to sue for peace, and after extorting heavy contributions from the cities of Asia Minor, sailed for Italy, and landed at Brundusium in the spring of 83 B. C. Marius was now dead, but his party were strong in numbers, if not in organisation; yet, before the close of 82 B. C., the Marian party in Italy was utterly crushed. In Spain, however, under the gallant and high-souled Sertorius (q. v.), it held out for ten years longer.

When S. felt himself master of the situation, his thoughts turned to revenge. Then followed the fearful period of the *proscriptions* (81 B. C.)—a virtual 'Reign of Terror' throughout Italy, the object of which was literally to extirpate the Marian party. In this, however, it was only partially successful; and the next generation saw that party rise to more splendid predominance than ever in the person of Julius Cæsar (q. v.), nephew of old Marius. In 81 B. C., S. got himself appointed dictator, an office which he held until 79 B. C. This period was signalised by his framing a series of laws—often spoken of collectively as the 'Sullan legislation'—the design of which was to make the senate and the aristocracy as vigorous and powerful as in the times of the Punic Wars, but which utterly failed of its end.

On resigning his dictatorship, S. retired to his fine estate at Puteoli, to enjoy at his ease those sensual pleasures to which he had been deeply addicted from his earliest manhood. Literature, wine, and women were luxuries in which he had always indulged, but now he wholly devoted himself to them—in a sort of *swinish* manner. It is strange to reflect that the man who undertook to legislate with the view of mending the public morals, should himself have surpassed in profligacy all his contemporaries. What more convincing proof could we have that morality in Rome had ceased to be more than a name! S.'s debaucheries hastened his end. He died 78 B. C., when only 60 years of age, of the disgusting disease known as *Morbus Pediculosus*.

SULLIVAN'S ISLAND, a large island, six miles below Charleston, South Carolina, U.S., between the harbour and ocean, the site of Fort Moultrie, one of its defences, and of the summer residences of the wealthy inhabitants. When Fort Moultrie was evacuated by Major Anderson, December 26, 1860, several batteries were erected on the shore of this island, bearing upon the channel and Fort Sumter.

SULLY, MAXIMILIEN DE BETHUNE, DUKE OF, the celebrated minister of Henry IV. of France, was the second son of François, Baron de Rosny, and was born at Rosny, near Mantes, in 1560. The Rosny family, an offshoot from the great House of Flanders, was never possessed of much wealth or influence, and had severely deteriorated in both respects during the early religious wars. S. was at an early age committed to the care of Henry of Navarre, the head of the Huguenot party, which not only obtained for him an excellent education, but laid the foundation of a companionship which lasted, without intermission, till Henry's death. After narrowly escaping during the St Bartholomew massacre, he accompanied his patron in his flight from court (1575), and during the civil war which followed, exerted himself to the utmost, by daring valour in the field and otherwise, to serve the master for whom he cherished the most absorbing devotion. After Henry's authority had been well established, S., who had for some years previous been his trusted adviser, became (1594) counsellor of state and of finance. The financial affairs of the country were then in a frightful condition; from the chief of the department down to the very lowest country agent, the administration was an organised system of pillage, and but a small percentage of the taxes levied found its way into the imperial treasury. The Baron de Rosny was the very man to remedy this state of matters; rude, obstinate, and haughty, but at the same time resolute, active, indefatigable, wholly devoted to his master's interests; and backed by the influence of Gabrielle d'Estrées, and by Henry's own clear-sighted convictions, he cared nothing for the clamour and hatred of the court, which had largely profited by the former state of chaos. Not content with regulating the affairs of the revenue from the seat of power, he made a tour through the chief provincial districts, armed with absolute authority, personally examined the accounts, dismissed or suspended delinquents, and largely replenished the treasury with the ill-gotten wealth which he compelled them to disgorge. By indomitable perseverance, he little by little brought the affairs of the country into an orderly state; although in the diminution of the expenditure his efforts were by no means so successful, as the king, his mistresses, and the other companions of his pleasures, combined to oppose all retrenchment as far as they were concerned. In 1596, the disposable revenue of the state was 7—9 millions; in 1609, it was no less than 20 millions, with a surplus of 20—22 millions in the treasury, and the arsenals and fleet in a state of excellent equipment. S., however, was more than a mere financier; he had the supreme charge of various other branches of the administration, zealously promoted agriculture by diminishing the taxes of the peasantry, encouraging export trade, draining marsh-lands, and constructing numerous roads, bridges, and causeways. S. was the servant of the king and government alone, and was of necessity disliked by the people for his severity, by the Catholics for his religion, and by the Protestants for his invariable refusals to sacrifice the smallest jot of his master's or the country's interest for their sake. Accordingly, with the death of Henry, his career of supremacy was at once ended, and he was forced to resign the superintendence of finance, 26th January 1611, though he retained his other high offices, and was presented by Marie de Médicis with 300,000 livres as acknowledgment of his services. He had been created Duke of Sully and Peer of France in February 1606. S. wrote three treatises on war and police, which are lost, and two pieces of verse, which are extant; but the work which will ever be connected with his name is the *Mémoires des sages et royales Œconomies d'Estat de Henry le Grand;* a dull, wearisome, and disorderly collection of writings, but of priceless value to a historian of Henry IV.'s time. S. printed the first two volumes of the *Mémoires* at his own château of Sully in 1634, the third and fourth were published at Paris in 1662, and the whole has been several times republished, as well as translated into English, German, and Russian. S. died at Villebon,

near Chartres (Eure-et-Loir), 22d December 1641. Artists have generally represented S. as older than Henry IV., while in reality he was seven years younger.

SULMO'NA, or SOLMONA, a city of Southern Italy, province of Aquila, in the Abruzzi. Pop. 13,585. It is situated in a vast fertile plain, watered by two rivers, and bounded by hills. It is very well built, having one very wide street in the centre of the city. There is a handsome town-hall, a cathedral, and a convent dedicated to S. Pietro Celestino, built with stones from the ancient *Corfinium*. It has paper manufactories, dye-houses, and tan-yards. S. was the birthplace of Ovid. In the 8th and 9th centuries, it was sacked by the Saracens, but was restored under the Normans, and has ever since been a flourishing and industrious city.

SU'LPHATES. See SULPHURIC ACID.

SU'LPHIDES, METALLIC, formerly known as *Sulphurets*, are combinations of sulphur with a metal. Many of them occur native, and form highly valuable ores. They are all solid at ordinary temperatures, and, with the exception of those of potassium, sodium, calcium, strontium, barium, and magnesium, are insoluble in water; they are, moreover, conductors of electricity. Many of them, especially of those that occur native, exhibit very brilliant and characteristic colours. The same metal may have several sulphides, and in general there is a sulphide for each oxide. The sulphides are, however, sometimes the more numerous. Most of these compounds may be fused at a heat a little above redness, and if the air be excluded, the protosulphides (those containing one atom of sulphur and one atom of metal) remain unaffected; but many of the higher sulphides, such as the disulphide of iron (Fe_2S_2) and the disulphide of tin (SnS_2), give off an atom of sulphur, and are reduced to protosulphides. If, however, there is a free admission of air or of oxygen gas to the heated sulphides, they are all decomposed, the sulphur becoming oxidised, and passing off as sulphurous acid (SO_2), while the metal usually remains in combination with oxygen. When heated before the blowpipe, most of the sulphides evolve an odour of sulphurous acid, and very small quantities of soluble sulphides may be detected in neutral or alkaline solutions by the addition of a solution of nitroferrocyanide of sodium ($Na_3Fe_2Cy_5(NO) + 2Aq$), when a magnificent purple colour, which, however, is not permanent, is evolved. It has very recently been discovered by Mr Barrett, and announced in his paper 'On some Physical Effects produced by the contact of a Hydrogen Flame with Various Bodies,' in the *Philosophical Magazine* for November 1865, that the sudden appearance of a blue colour when the hydrogen flame is brought in contact with a body containing sulphur, is a most delicate test for the presence of this element, detecting it even when the nitro-prusside of sodium test fails. By this test Mr Barrett detected $\frac{1}{1000000}$th of a grain of sulphur.

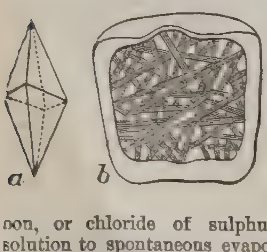
The sulphides are prepared in various ways, of which it is sufficient to notice the most important. (1.) The protosulphides of the metals of the alkalies and alkaline earths may be obtained by decomposing their sulphates by igniting them in closed vessels with charcoal, the oxygen being removed in the form of carbonic oxide. (2.) Many of the metals, when heated with sulphur, combine directly with it; sulphide of iron, for example, is usually prepared in this manner. (3.) Hydrated sulphide of tin, titanium, molybdenum, tungsten, vanadium, arsenic, antimony, bismuth, copper, lead, mercury, silver, gold, and platinum with its allied metals, may be obtained by passing a stream of sulphuretted hydrogen through neutral or acid solutions of their salts, when they are precipitated in an insoluble form; and the hydrated sulphides of zinc, iron, manganese, cobalt, and nickel may be prepared by double decomposition, by mixing a solution of the salt of the metal with a solution of a sulphide of one of the metals of the alkalies, as, for example, sulphide of potassium: thus, sulphate of zinc, if mixed with sulphide of potassium, yields sulphate of potassium, which remains in solution, and sulphide of manganese, which falls as an insoluble precipitate. 'In many cases,' says Professor Miller, 'the atoms of these hydrated sulphides are characteristic of the metal; for example, the hydrated sulphide of zinc is white; that of manganese, flesh red; those of cadmium, arsenic, and persulphide of tin are yellow; that of tersulphide of antimony is orange red; and that of the hydrated protosulphide of tin is chocolate brown. The sulphides of molybdenum, rhodium, iridium, and osmium are brown, each with its peculiar shade, whilst in a large number of instances—including the sulphides of iron, cobalt, nickel, uranium, vanadium, bismuth, copper, lead, silver, mercury, gold, platinum, and palladium—the precipitated sulphides are of a black, more or less pure.'—*Inorganic Chemistry*, 2d ed., 1860, p. 322. A recollection of the colours of these precipitates will save the young chemist a large amount of labour in testing for the presence of the metals.

SULPHOCYA'NOGEN AND THE SULPHOCY'ANATES. The former of these terms is given to a monobasic radical, CNS or CyS, which has never yet been isolated, but which forms an acid compound, known as hydrosulphocyanic acid (CNHS), with hydrogen, and yields numerous metallic salts. These salts, known as sulphocyanates, may be represented by the general formula, Cy.M.S, where M represents any metal. The sulphocyanates of potassium, sodium, and ammonium are crystallisable and soluble in water; those of the heavy metals are comparatively insoluble. These salts do not possess the poisonous character of the cyanides. *Sulphocyanate of potassium* (KCyS) is anhydrous, but very deliquescent, and occurs in long streaked colourless prisms, somewhat resembling nitre both in appearance and taste; it is extremely soluble in water, and fuses on the application of a gentle heat. The *sulphocyanate of mercury* is a white powder which possesses the property of swelling or growing in size to an almost incredible degree when moderately heated, so as to decompose it into a mixture of mellone (C_9N_{13}) with a little sulphide of mercury. The resulting mass often assumes a most fantastic shape, and is sufficiently coherent to retain its form; it is of a yellow colour externally, but black within. It is this sulphocyanate which is the ingredient of the well-known toy known as 'Pharaoh's serpents.' Each serpent consists of a little cone of tinfoil, resembling a pastille in shape, and filled with the above-named compound. On lighting the cone at the apex, there begins to issue from it a thick serpent-like coil, which continues twisting and increasing in length to an extraordinary degree, the serpent-like shape resulting from the salt being burned in the tinfoil cone. The compound is readily obtained by precipitating a strong solution of pernitrate of mercury with sulphocyanate of ammonium, which is most cheaply prepared by Mr. Wood's method from bisulphide of carbon.

SULPHOVI'NIC or ETHYL-SULPHURIC ACID ($(C_2H_5)HSO_4$) is formed by mixing alcohol with an equal bulk of oil of vitriol. Great heat

is evolved, and the two bodies enter partially into combination; this new compound acid possessing only half the saturating capacity of sulphuric acid. In connection with the theory of the formation of ether from alcohol and sulphuric acid, it may be observed that this sulphovinic acid is developed as an intermediate product, if the temperature be raised to 212°, but not otherwise. This is one of the class of acids to which the term *vinic acids* is applied.

SULPHUR (symb. S, equiv. 32, sp. gr. of rolled sulphur, 1·98; of octahedral crystals, 2·05; and of amorphous sulphur, 1·957; sp. gr. of vapour, 6·617 at 824, and 2·2 at 1900°, atmospheric air being the unit of comparison for the vapour) is one of the most important of the non-metallic elements. At an ordinary temperature, it exists as a solid, brittle, tasteless, and inodorous body, of a characteristic yellow colour, and insoluble in water. A piece of solid sulphur, heated to a temperature of 239°, fuses into a thin yellow liquid; while in closed vessels, it may, by a further heat, be distilled, the boiling-point being about 824°, and at this temperature it yields a deep yellow vapour, of sp. gr. 6·617. When the sulphur-vapour comes in contact with cold air, it condenses in the form of a fine yellow powder, known as *Flowers of Sulphur*. If fused sulphur be rapidly cooled, it solidifies into a compact mass, of a granular crystalline texture; and if, in its liquid state, it be allowed to run into cylindrical wooden moulds, we obtain it in the ordinary form of roll-sulphur, or common brimstone; if, on the other hand, it be allowed to cool slowly, it crystallises in long, glistening, deep, yellow, oblique prisms, with a rhombic base, which, however, soon lose their most characteristic properties. As native sulphur is frequently met with in yellow crystals, whose form is derived from the octahedron with a rhombic base, it is obviously a dimorphous substance. It has been already stated that sulphur fuses at 239°; from that temperature up to 280°, it forms a yellow, transparent, limpid liquid; as the heat increases, the colour becomes brown, and almost black, and the liquid becomes viscid, these changes being very distinctly seen at 350°. If the external application of heat be steadily continued, it will be found that for a while the temperature remains constant, but it afterwards rises, and at nearly 500°, the sulphur again liquefies, although less completely than when first melted. If it be now suddenly cooled by pouring it, in a slender stream, into cold water, we obtain a spongy, tenacious, and plastic mass, which may be drawn out into elastic threads, whose colour, after they have cooled, varies from an amber to a deep brown colour, according to the heat that has been employed. After some hours, the ductile sulphur loses its characteristic properties, increases in density and returns to the brittle form; or, if it be heated to 212°, it suddenly returns to the brittle condition; the temperature rising to 230° during the change. Hence, sulphur may be obtained in three (if not in more) allotropic states, which are distinguished by the symbols Sα, Sβ, Sγ. The first variety, Sα, is the native octahedral crystal of sulphur (a); it may be obtained artificially by dissolving sulphur in bisulphide of carbon, or chloride of sulphur, and submitting the solution to spontaneous evaporation. These crystals are semi-transparent, of an amber-yellow colour, and undergo no change on exposure to the air. The second variety, Sβ, is the oblique prismatic crystal already described as being formed when fused sulphur cools slowly. The best method of obtaining these crystals is to melt a few pounds of sulphur, and allow it to solidify on the surface. On perforating the external crust with a hot wire, and pouring out the sulphur that remains liquid, the interior of the cavity is found to be traversed in all directions by these crystals (b), occurring as transparent brownish needles, having a specific gravity considerably less even than that of roll-sulphur. On exposure to the air, they soon lose their coherence, and form an opaque and crumbling mass, consisting of minute rhombic octahedra. This conversion of the prismatic into the octahedral form takes place immediately, if the prisms are immersed in bisulphide of carbon. The third variety, Sγ, is the plastic amorphous sulphur, which has been sufficiently described. If sulphur be frequently heated to 600°, and suddenly cooled, a black variety of this element is produced; and a red variety has been obtained, but the redness is now supposed to be due to the presence of a trace of some fatty body.



a *b*

Sulphur is a bad conductor of heat, and the mere heat of a warm hand often causes it to crackle, and even to fall to pieces, from the unequal expansion. It is an insulator of electricity, and becomes negatively electric by friction. It is slightly soluble in alcohol, ether, and the fatty oils; its best solvents being the bisulphide of carbon and chloride of sulphur. When it is heated in the air, it takes fire at about 470°, burning with a blue flame, and becoming converted into sulphurous acid, whose pungent suffocating fumes are characteristic of sulphur. This element is second only to oxygen in its powerful affinity for other elements, with most of which it unites, and often in several proportions. With most of the metals it combines very readily, and in some cases, with a development of light and heat; thus, silver and copper burn in sulphur vapour just as iron-wire or zinc-foil burns in oxygen. In consequence of its power, with the aid of heat, of forming sulphurous acid with the oxygen of the air, and thus rendering the latter incapable of supporting combustion, burning sulphur may be usefully employed for the extinguishing of fire—as, for example, in chimneys.

Sulphur occurs very widely distributed in the mineral kingdom, partly free and partly combined with other elements. The free sulphur is either found pure in regularly formed crystals, or intimately mixed with earthy matters. The principal sources of crystalline sulphur are Urbino in Italy, Girgenti in Sicily, and Radoboy in Croatia; while the earthy sulphur is mainly derived from Italy, Moravia, and Poland. Iceland is rich in both varieties, and California supplies large quantities for her oil of vitriol works. At present, by far the largest quantity of the sulphur employed in Europe comes from Sicily; and, as a general rule, it is abundant in volcanic districts. In the form of sulphide, sulphur occurs abundantly in combination with iron, copper (iron and copper pyrites), lead (galena), zinc (blende), &c., the bisulphide of iron (or iron pyrites) furnishing much of the sulphur that is employed in the manufacture of sulphuric acid. Sulphur is still more extensively distributed in the form of sulphates, the sulphates of calcium, magnesium, barium, &c. being abundant natural productions. In the vegetable kingdom, sulphur is a constituent (although only to a small amount) of the albuminous bodies which are so widely diffused in plants; and of certain volatile irritant oils, as those of mustard, garlic, assafœtida, &c.; and, moreover, the vegetable juices contain it in the form of

certain sulphates. In the animal kingdom, it is not only a constituent of the albuminous, fibrinous, and gelatinous tissues, but of the hair, saliva, bile, urine, &c. The two animal substances in which it is most abundant are Cystine (q. v.), an occasional constituent of urinary calculi, and Taurine (q. v.), a constituent of the bile, in both of which it forms about a quarter of the entire weight.

It would be out of place in this article to enter into details regarding the *extraction* or *preparation* of sulphur. It is sufficient to state that the grosser impurities are removed by crude processes of fusion and distillation at or near the place from whence it is obtained. That which is imported into Britain undergoes further purification. What is called *refined sulphur* is that purified by distillation in a large cast-iron still, and condensed in a receiver kept cool. When the vaporised sulphur is condensed in a large chamber, it is obtained in the form of *sublimed sulphur*, or *flowers of sulphur;* but as the walls get hot, it melts and collects on the floor, and is run into cylindrical wooden moulds, from which, when cool, it is taken out as *roll* or *stick sulphur.* The residue left in the retort is a mixture of sulphur with various impurities. Under the names of *Black Sulphur*, or *Sulphur vivum* (commonly inquired for at the chemist's under the title of *Sulphur of Ivy*), it is used in veterinary medicine, and for the purpose of dressing mouldy hops. Sulphur is thrown down from certain of its compounds (as from a strong solution of a polysulphide of calcium, sodium, or potassium) by dilute hydrochloric acid; it falls as a grayish-white, very fine, light powder, known in the Materia Medica as *milk of sulphur*, or *precipitated sulphur.* For the method of obtaining sulphur from iron pyrites, we must refer the reader to Miller's *Inorganic Chemistry*, 2d ed. p. 154. The proceeding is usually conducted on a large scale, 2000 tons of pyrites being roasted at once, the roasting extending over five or six months, and the final result being about 20 tons of sulphur. The most common impurities met with in ordinary commercial sulphur are selenium and realgar (bisulphide of arsenic). Flowers of sulphur frequently exhibit a slight acid reaction, in consequence of a little sulphurous acid clinging to them. By rinsing them with water, this impurity is at once removed.

Sulphur is extensively employed in the arts and manufactures; as in the manufacture of matches, gunpowder, &c. When converted into sulphurous acid, it is employed as a powerful bleaching agent, and also for the destruction of insects, fungi, &c.; but its chief consumption is in the manufacture of sulphuric acid.

Sulphur forms two oxides, viz., sulphurous, or sulphurous anhydride (SO_2), and sulphuric, or sulphuric anhydride (SO_3): each of these when united with 1 atom of water forming, respectively, sulphurous acid ($H_2O.SO_2{=}H_2SO_3$) and sulphuric acid ($H_2OSO_3{=}H_2SO_4$). S. forms with oxygen seven acids:

Sulphurous acid,	H_2SO_3.
Sulphuric acid,	H_2SO_4.
Hyposulphurous, or Thiosulphuric acid,	$H_2S_2O_3$.
Hyposulphuric, or Dithionic acid,	$H_2S_2O_6$.
Trithionic acid,	$H_2S_3O_6$.
Tetrathionic acid,	$H_2S_4O_6$.
Pentathionic acid,	$H_2S_5O_6$.

The last five of these acids have never been obtained in the anhydrous form. We shall only notice the most important members of this group, viz., the first three of them, and of these, the second, *Sulphuric Acid*, is so extremely important, that it is discussed in a special article. (The last three derive the essential portion of their name from the Greek word *theion*, sulphur.)

SULPHUROUS ACID, or SULPHUROUS ANHYDRIDE (H_2SO_3), occurs under the ordinary relations of temperature and pressure as a colourless gas, possessing the suffocating odour of burning sulphur. In its concentrated form, it is quite irrespirable, and in a diluted state it excites cough, and produces the symptoms of an ordinary catarrh. It is not only incapable of burning, but it rapidly extinguishes the flame of burning bodies. It is very freely soluble in cold water, which at 32° takes up nearly 69 times its volume of the gas, while at 75° it only takes up 32 volumes; the solution known as *Aqueous Sulphurous Acid* having at first the same smell and taste as the gas, but soon absorbing oxygen from the air, and becoming converted into sulphuric acid. By the action of cold, sulphurous acid may be condensed to a colourless transparent limpid liquid, which freezes at −105°, forming a transparent crystalline solid. The specific gravity of the gas is 2·247 (atmospheric air being the unit), and that of the liquid is 1·49 (water being the unit), the solid being considerably heavier. Although dry sulphurous acid gas and dry oxygen, when mixed, exert no action on one another, there are many conditions under which sulphurous acid rapidly absorbs oxygen, and is converted into sulphuric acid. It has been mentioned that this takes place if the gas be dissolved in water; a similar action takes place under the influence of hydrated nitric acid, iodic acid, and certain metallic oxides. For example, oxide of lead, when immersed in the gas, burns and is converted into white sulphate of lead ($Pb_2O + HSO_3 = Pb_3 + SO_4$). Hence, sulphurous acid is a powerful reducing or deoxidising agent. This gas is a common and abundant product of volcanic action, and is occasionally met with in solution in the springs in volcanic regions. It may be prepared artificially by simply burning sulphur in the air, or in oxygen gas, or by heating in a flask 4 parts of flowers of sulphur mixed with 5 parts of powdered black manganese, sulphurous acid and sulphide of manganese being the products, as shewn by the equation $2S + Mn_2O_2 = SO_2 + Mn_2S$. In consequence of its solubility in water, this gas should be collected over mercury. In addition to the uses of sulphurous acid as a bleaching agent, it is valuable both as a disinfectant agent and as a powerful antiseptic; its latter property has been applied to the preservation of meat, which, after exposure to this acid, will keep fresh for years, if it be enclosed in metallic canisters filled with nitrogen, to which a little binoxide of nitrogen has been added, to remove any trace of oxygen. But by far its most important use is, as a first stage in the manufacture of sulphuric acid. In combination with bases, this acid forms the *sulphites*—a class of salts which, excepting the sulphite of sodium, are of little practical importance, except for their power, when moist, of extracting oxygen, and thus acting as reducing agents. For example, the salts of the sesquioxide of iron are reduced by them to salts of the protoxide.

HYPOSULPHUROUS ACID ($H_2S_2O_3$) is scarcely known in a state of combination with bases; for on attempting to separate the acid from the base, the former becomes almost immediately decomposed into sulphur and sulphurous acid. The most important of its salts is the *Hyposulphite of Sodium* ($Na_2S_2O_3.5H_2O$), whose mode of preparation and characters are described in the article SODIUM. This and other soluble hyposulphites may be easily recognised by the facility with which they dissolve the haloid salts of silver, forming a solution of an extremely sweet taste, and containing a double hyposulphite of silver and sodium, with an admixture of chloride, iodide, or bromide of sodium. It is this power of dissolving those salts of silver which are insoluble in water

that renders the hyposulphite of sodium so important an agent in photography. The only other salt of this acid which we shall notice is the *Hyposulphite of Gold and Sodium* ($AuNa_3S_4O_6.2H_2O$), which may be prepared by mixing concentrated solutions of 1 part of chloride of gold and 3 parts of hyposulphite of sodium, and adding alcohol, when the required salt is precipitated. It is used for gilding the daguerreotype plate, and for colouring the positive proof obtained in photographic printing.

With hydrogen, sulphur forms two compounds, viz., *Sulphuretted Hydrogen*, or *Hydrosulphuric Acid* (q. v.), and *Persulphide of Hydrogen*, an oily liquid, having the smell and taste of sulphuretted hydrogen, and in many of its properties having an analogy to binoxide of hydrogen. Sulphur combines with carbon to form a *Disulphide of Carbon* (CS_2), a very volatile colourless liquid, of a high refractive power, of an acrid and pungent taste, and a very disagreeable odour. It is heavier than water, in which it is insoluble, but dissolves freely in alcohol and ether, and is the best solvent for sulphur and phosphorus. Bisulphide of carbon does not occur as a natural product, but may be obtained by heating fragments of charcoal to bright redness in a porcelain tube, and passing sulphur vapour along it. Its vapour, when freely inhaled, exerts a similar anæsthetic action with those of chloroform and ether. Workmen in caoutchouc or other manufactures in which bisulphide of carbon is used as a solvent, suffer very much from prolonged exposure to its vapour, which produces headache, loss of appetite, impairment of vision and hearing, and causes general derangement of health by its deleterious action on the nervous system. Sulphur combines with chlorine in several proportions, the most important of these compounds being the *Disulphide of Chlorine* (Cl_2S_2) and the *Protosulphide of Chlorine* (Cl_2S). Both of them are liquids, and are formed by the direct action of the combining elements. The disulphide is a yellow volatile liquid with a penetrating and disagreeable odour. When dropped in water, it sinks to the bottom (its spec. grav. being about 1·687), and is slowly decomposed into hydrochloric and various sulphur acids, and free sulphur. It is capable of dissolving about 67 per cent. of sulphur at an ordinary temperature, and, like disulphide of carbon, is extensively employed in vulcanising india-rubber. By passing dry chlorine gas through disulphide of chlorine at various temperatures, liquids are produced containing various proportions of sulphur and chlorine both above and below those required by the formula Cl_2S, or protosulphide of chlorine.

With regard to the history of sulphur and its compounds, it may be observed that sulphur seems to have been known from the earliest times, and that sulphuric acid was most probably known to the Arabians. The manufacture of English sulphuric acid dates, however, only from the 18th century. Sulphurous acid was first investigated by Stahl, Scheele, and Priestley; hyposulphuric acid was discovered by Welter and Gay-Lussac; hyposulphurous acid, by Gay-Lussac and Herschel; trithionic acid, by Langlois; tetrathionic acid, by Fordos and Gelis; and pentathionic acid, by Wackenroder. Scheele was the first who accurately studied hydrosulphuric acid, or sulphuretted hydrogen.

Sulphur is used to a considerable extent and for very different purposes in medicine. It is given internally either as sublimed sulphur (flowers of sulphur) or as precipitated sulphur (milk of sulphur), in somewhat large doses, as a mild cathartic—its purgative effects being due to its stimulating the muscular coat of the intestines. In consequence of its being both gentle and sure in its action, it is the best purgative to employ in cases of piles or in stricture or other painful affections of the rectum. The only objection to its use is that, from its becoming partly converted in the system into sulphuretted hydrogen, the evacuations, and even the insensible perspiration, often become abominably fœtid, and continue so for some time after the primary operation of the medicine. As a purgative, the dose is about two drachms, made into an electuary with treacle or honey. It is, however generally combined with jalap and cream of tartar.

The *Confection of Sulphur* of the Pharmacopœia is composed of sulphur, cream of tartar, and syrup of orange-peel rubbed together—the dose being from half an ounce to an ounce, or from one to two tablespoonfuls. In small doses, sulphur is of great value in cases of atonic gout and chronic rheumatism. An electuary known as *The Chelsea Pensioner*, consisting of two ounces of sublimed sulphur, one ounce of powdered rhubarb, half an ounce of resin of guaiacum, one ounce of cream of tartar, half an ounce of ginger, and two drachms of powdered nutmegs, with as much treacle as is necessary, in doses of one or two teaspoonfuls night and morning, is a combination of great value in these cases. It originally gained its reputation by curing Lord Amherst of rheumatism, and is still a favourite remedy at Chelsea Hospital. Dr Neligan states that steaming the lower bowel, by sitting over the vapour of warm water upon which a tablespoonful of flowers of sulphur had been sprinkled, constitutes a most valuable remedy in what is popularly known as a 'fit of the piles.' The external use of sulphur in the form of ointment has been already noticed in the article ITCH. It is also used externally in many other cutaneous disorders, particularly in lepra and psoriasis; and in chronic cases, its application in the form of vapour is often of great service.

SULPHU'RIC ACID, or, more correctly, Hydrated Sulphuric Anhydride (H_2SO_4), is the chemical name of the liquid commercially and popularly known as *Oil of Vitriol.** It is a dense, colourless, oily liquid, without smell, of a spec. grav. of 1·846 at a temperature of 60°, and of an intensely acid taste and reaction. It has a powerful caustic action, and chars and destroys organic matters from its strong affinity for water; and in consequence of this destructive property, it must always be handled with the greatest caution. So powerful is this affinity, that if the acid be exposed for a few days to the air in a shallow dish, so as to present a large surface, it often doubles its weight by absorbing aqueous vapour from the air; and in consequence of its possessing this property, it is extensively used in laboratory operations as a desiccating agent. It mixes completely with water in all proportions, and as great heat is given out at the moment of mixture, the dilution should be performed by very gradually adding the acid to the water. When cold, the mixture occupies less bulk than the two components previously occupied. This acid freezes at a temperature of $-15°$, and boils at 620° (or according to Marignac, at 640°), and just above the boiling-point, it assumes the form of a vapour, with a spec. grav. of 2·15. There are two, if not more, well-defined hydrates of sulphuric acid, namely, the monohydrate ($H_2SO_4.H_2O$) and the dihydrate ($H_2SO_4.2H_2O$). The first has a spec. grav. of 1·78, and solidifies at 46½° to 48° F., forming a mass of colourless, six-sided prisms, whence it is called glacial sulphuric acid. It boils at 392°—410° F.,

* It received this name from having been first produced by the distillation of green vitriol (sulphate of iron); Basil Valentine being usually credited with the discovery. See ALCHEMY.

giving off a weak acid vapor. It may be obtained by evaporating any dilute sulphuric acid at a temperature of 392° F. until it ceases to lose water. The second hydrate results from the mixture of 1 atom of oil of vitriol with 2 atoms of water. This preparation corresponds to the maximum condensation, nearly 8 per cent., which results from the union of the acid with water. Its spec. grav. is 1·62; and its boiling-point 348° F. It may be obtained by evaporating any dilute acid at 212° F. until it ceases to lose water.

Fuming sulphuric acid, known as *Nordhausen* or *Saxon*, is distilled from dehydrated sulphate of iron. It is a heavy, brown, oily liquid, having a spec. grav. of 1·9 and a composition corresponding nearly to the formula $H_2S_2O_7$ or $H_2SO_4.SO_3$. It solidifies at 32° F. into colourless, transparent crystals, and when gently heated breaks up into sulphuric oxide (SO_3), which distils over, and sulphuric acid (H_2SO_4), which remains. For a notice of anhydrous sulphuric acid, which is not properly an acid, see SULPHURIC ANHYDRIDE.

Sulphuric acid in its free state is a very rare natural product; although, in combination with bases, it is common in the animal and vegetable, and abundant in the inorganic kingdom. The only cases in which it is known to occur free are certain American rivers, especially the Rio Vinagre, and some lakes in Tennessee and in Java; and it has been found to be a normal constituent of the saliva of *Dolium galia*, a species of snail found in Sicily. In all these cases, the acid is, of course, in an extremely diluted form. In plants it exists in the juices, and in animals in the blood and its derivates chiefly in the form of sulphates of the alkalies; while in the mineral kingdom it occurs as gypsum (sulphate of calcium), heavy spar (sulphate of barium), celestine (sulphate of strontium), &c.

Sulphuric acid may be prepared on a small scale by boiling sulphur in *aqua regia*, or in nitric acid, the sulphur becoming gradually oxidised into sulphuric acid. As a general rule, however, the commercial acid is employed even for laboratory experiments. See below.

In order to obtain the acid in a pure form, suitable for medical use or medico-legal analyses, it must be redistilled with sulphate of ammonia in a retort containing a few slips of platinum foil, the first and last portions being rejected. The distillation is attended with violent concussions, partly owing to the high specific gravity of the acid, and partly owing to its high boiling-point, and this convulsive action is moderated mechanically by the platinum slips. Sulphuric acid thus prepared according to the directions of the British Pharmacopœia may be regarded as perfectly pure, presuming arsenic is not present. Strong sulphuric acid has comparatively little action on the metals except at a high temperature, when it dissolves them, and, at the same time, undergoes partial decomposition; the metal being oxidised by a portion of the acid which becomes decomposed into oxygen and sulphurous acid, and then uniting with a portion of undecomposed acid to form a sulphate. Silver, copper, mercury, arsenic, antimony, bismuth, tin, lead, and tellurium are thus acted on. Gold, platinum, rhodium, and iridium are not affected by the acid even at a boiling temperature. The more oxidisable metals, such as zinc, iron, nickel, and manganese, are readily soluble in the dilute acid, water being decomposed, and hydrogen liberated, while the oxygen of the water unites with the metal; and the metallic oxide, at the moment of its formation, combines with the sulphuric acid to form a sulphate.

The *sulphates*—or salts formed by the combination of sulphuric acid with a base—are generally composed, as in the case of green vitriol ($Fe_2SO_4.7H_2O$), of 1 equivalent of acid and two of the metal, with or without water of crystallisation. With the alkalies, this acid also forms acid salts, as bisulphate of potassium, and in a few cases—copper, for example—it forms basic salts. The insoluble sulphates, such as that of barium, may be obtained by precipitating a soluble salt of the base by a soluble sulphate; thus, nitrate of barium and sulphate of sodium yield an insoluble sulphate of barium and nitrate of sodium, which remains in solution. The soluble sulphates may be prepared by dissolving the oxide or carbonate in dilute sulphuric acid, in those cases in which the metal itself is not readily attacked by the acid. Sulphuric acid and the soluble sulphates are easily detected by their yielding, with a solution of a barium salt, a white precipitate of sulphate of barium insoluble in acids.

This acid is employed in the arts and manufactures for a large number of purposes. Its use as a desiccating agent for laboratory purposes has been already noticed, and its application to the development of oxygen gas has been described in the article on that element. But its greatest consumption, doubtless, is in the preparation of the *Salt-cake*, which is used in the manufacture of Carbonate of Soda (q. v.).

In medicine, a *dilute sulphuric acid*, formed by gradually mixing three fluid ounces of the strong purified acid with thirty-five fluid ounces of water, or *aromatic sulphuric acid* (known also as *elixir of vitriol*), prepared by mixing three ounces of sulphuric acid with a quart of rectified spirit, adding cinnamon and ginger, digesting for a week, and filtering, are almost always employed. In doses of from ten to thirty minims, properly diluted, these preparations exert a strong astringent power, and are serviceable in all forms of passive hæmorrhages, and in checking inordinate discharges when they arise from debility. In ordinary diarrhœa, and even in the premonitory diarrhœa of cholera, dilute sulphuric acid is of great use. In painters' colic, it is given in order to convert any lead that is absorbed into an insoluble sulphate, which is inert. Sulphuric acid lemonade is also used as a prophylactic against the disease. As this acid exerts a deleterious action on the teeth, it should be directed to suck it through a quill. In some cases, it is prescribed not so much for its specific as for its solvent power; with this object, it is usually prescribed with quinine. The strong acid is used in surgery as a caustic. In cases of *poisoning* with this acid, the most prominent features are: burning pain extending from the mouth to the stomach, intense pain in the bowels, vomiting, great prostration, coldness of the surface, and fœtor of the breath. The mucous membrane of the parts injured by the acid is at first converted into a white slough, which soon becomes black, and the patient usually dies from exhaustion within twenty-four hours. The best antidotes are the alkaline bicarbonates, or carbonate of magnesium. If the primary symptoms be conquered, the patient often dies subsequently from stricture of the œsophagus.

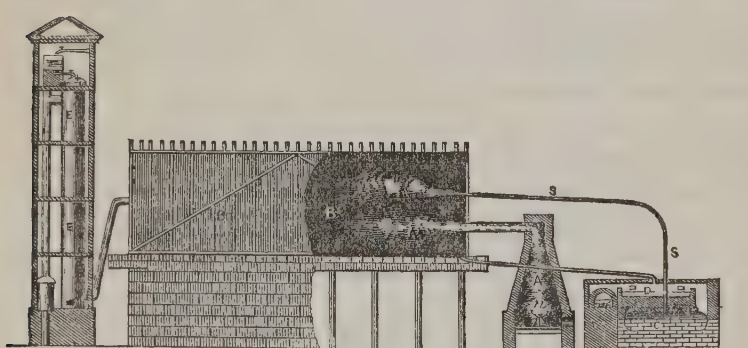
Sulphuric Acid Manufacture.—There are two distinct processes by which sulphuric acid is at present prepared on a large scale—viz., by the distillation of green sulphate of iron—the original process of Valentine; and by the oxidation of sulphurous acid through the agency of nitrous acid and hyponitric acid. The first process is chiefly employed at Nordhausen, in Prussia, and is thus described by Fownes: 'The sulphate of iron, derived from the oxidation of iron pyrites, is deprived by heat of the greater part of its water of crystallisation, and subjected to a high heat in earthen retorts, to which receivers are added as soon as the acid begins to distil over. A part gets

decomposed by the very high temperature; the remainder is driven off in vapour, which is condensed by the cold vessel containing a very small quantity of water or common sulphuric acid. The product is a brown oily liquid of about 1·9 specific gravity, fuming in the air, and very corrosive. It is chiefly used for the purpose of dissolving indigo.'

The second method is that universally followed in Great Britain, the germs of which were likewise discovered by Valentine. He observed that when the fumes of burning sulphur were collected under a bell jar, slightly moistened with water, a small quantity of liquid was deposited. This liquid, which was simply sulphuric acid, on being concentrated from its solution by boiling, was long sold as oil of sulphur *per campanum* at prices as high as 2s 6*d*. per ounce.

About the year 1740, the French chemists Lefevre and Lemery suggested that, by the use of nitre along with the sulphur, the operation might be conducted in close vessels, and a much greater quantity of acid might be produced. This idea was acted on in England by a Dr Ward, who established works at Twickenham and Richmond, conducting his manufacture by burning the mixed sulphur and nitre in large stoppered glass receivers, into each of which a small quantity of water was first introduced. The substitution, by Dr Roebuck of Birmingham, of lead chambers in place of the glass vessels, may be regarded as essentially the establishment of the process of manufacture followed at the present day. Dr Roebuck established his first works at Prestonpans in 1749.

The first stage in the manufacture of sulphuric acid is the preparation of sulphurous acid by the burning of sulphur or of iron pyrites. Previous to the year 1838, Sicilian sulphur was almost exclusively used in the manufacture, but in that year, the very ill-advised establishment of a monopoly of the sulphur trade by the Sicilian government, and its consequent increase in price, diverted the minds of manufacturers to the employment of iron pyrites (sulphuret of iron) the use of which, as a source of sulphurous acid, was already not unknown. The monopoly was quickly abolished, on the representations of the English government, but not until it was demonstrated that the world was independent of Sicily both for sulphuric acid and sulphur. Iron pyrites is now much more used than sulphur, and the only hindrance to its universal adoption is the presence of foreign matter in the pyrites, the most deleterious being arsenical compounds; and it has hitherto been found impracticable to free the sulphuric acid wholly from the arsenious acid which



Manufacture of Sulphuric Acid:
A, sulphur-burner, or furnace; B, lead chamber, shewn in section at B′; C, steam boiler; D, leaden pan; E, coke tower; S, steam-pipe; *n*, nitre pot.

consequently accompanies it. This renders the acid prepared from pyrites inapplicable for many purposes.

When sulphur is the material used for producing the sulphurous acid, it is burned in an oven or 'burner' (A) of brick-work, having a sole or bottom of iron, termed the 'burner-plate.' Under this, a small fire is at first lighted, which is allowed to go out after the sulphur has ignited. A little above the sulphur, a small pot, called the nitre pot, *n*, is either placed on a stand, or hung from the roof, filled with a quantity of either nitrate of soda or nitrate of potash, with sulphuric acid sufficient for its decomposition—8 or 10 lbs. of the nitre, with 5 or 6 lbs. of sulphuric acid, being allowed for every cwt. of sulphur. The decomposition of the nitre by the action of heated sulphuric acid, furnishes nitric acid fumes, which go over into the chamber along with the sulphurous acid. The sulphurous readily abstracts from the nitric acid the additional equivalent of oxygen required for its conversion into sulphuric acid, reducing the nitrous compound from nitric acid, HNO_3, to nitric oxide, NO. Nitric oxide in its turn quickly converts itself into nitric peroxide, NO_2, by the abstraction of an additional equivalent of oxygen from the air that is constantly entering the chamber through the burners. Again, in the presence of moisture which is supplied by a jet of steam from the boiler C, sulphurous acid readily deprives the nitric peroxide of 1 equivalent of oxygen, and thus forms another volume of sulphuric acid, and again liberates nitric oxide. The reaction may be expressed as follows, $NO_2 + SO_2 + H_2O = H_2SO_4 + NO$. The nitric oxide is again ready once more to seize upon the oxygen of the air, and would continue so acting and reacting ***ad infinitum***, were it not carried forward and out by the chimney provided for the escape of the freed nitrogen.

The chamber is an immense box or room of lead, bound together with a strong framework of timber, and generally raised on arches several feet above the ground. Chambers vary in size from 60 to 140 feet in length, and from 20 to 40 feet in width and height. Curtains of lead proceeding alternately from the bottom to near the top, and *vice versâ*, are very frequently used; they serve to retard the progress of the gases, and thus insure the transformations desired. The floor of the chamber is covered with water, into which the sulphuric acid falls as it is formed; and when this solution attains a certain strength, it is tapped off for concentration. When the gases reach the chimney, on account of the reactions of the nitrous compounds already explained, a large amount of nitrous acid would not only be wasted, but would also be deleterious to the neighbourhood, were steps for its recovery not adopted. This recovery is usually effected by means of a tower filled with coke, E, down which a constant stream of strong sulphuric acid trickles, the acid absorbing the nitrous fumes in their way upwards. Instead of a single chamber, curtained off or not as the case may be, sometimes three or five distinct chambers, connected by pipes, are employed, thus

communicating directly with the burners being termed working chambers, and the others receiving chambers, the last either acting as or communicating with a condenser or chimney. In France and Germany, the apparatus employed is generally of a more complicated nature, but in principle the operations are identical.

When iron pyrites is used as the source of sulphurous acid, a furnace somewhat on the principle of the ordinary lime-kiln is required. The pyrites is broken into pieces like nuts, washed, and spread in layers on plates heated to redness, and frequently stirred; or a quantity of coke is introduced with the first charge, and the heat evolved by the burning sulphur is thereafter sufficient fuel for the fresh charges. The exhausted ore is frequently sufficiently rich in copper for its extraction; indeed, when there is not more than 2½ per cent. of that metal present in pyrites, it is now recovered, and this has led to the establishment of copper-smelting works in connection with great chemical works near Newcastle and Manchester. The large chambers required, the increased labour, the greater quantity of nitre wasted, and other circumstances, tend to make the cost of acid from both sources nearly equal. *Alkali waste* from the soda works, consisting of sulphide of calcium, sulphide of sodium, &c., is also employed for the reproduction of sulphur and sulphuric acid.

In consequence of strong sulphuric acid absorbing both sulphurous acid and nitrous acid, the acid requires to be drained off from the chamber while the solution is comparatively weak, at which strength, viz., of a specific gravity of about 1·4, it is used for some purposes in the arts, under the name of 'Chamber Acid.' This is concentrated by evaporating, in leaden pans, D, till it reaches the specific gravity of 1·6, then boiling in a platinum retort, on which strong acid does not act, even at high heat, or in large flint-glass retorts. A platinum retort has been made for the concentration of 8 tons of acid per day, and valued at £2500. Large glass retorts, which were used before the introduction of the platinum retorts, are again coming into favour with manufacturers. The only objection to their use is the great expense arising from frequent breakages, and consequent loss of both acid and retort.

The manufacture of sulphuric acid is a very extensive industry; immense quantities of it being consumed in the manufacture of soda, in that of bleaching-powder, in calico-printing and dyeing, and, in fact, in most chemical operations both in the manufactory and the laboratory. For details respecting the manufacture of sulphuric acid, see Richardson and Watts's *Chemical Technology*, vol. i., and for popular views of modern processes, J. Lawrence Smith's *Progress and Condition of Industrial Chemistry*, in *Rep. of United States Commissioners to the Paris Exhibition*, 1867, Washington, 1869.

SULPHURIC ANHYDRIDE, formerly known as ANHYDROUS SULPHURIC ACID, is commonly represented by the formula SO_3, but reasons have been advanced for believing that the formula should be doubled—or, in other words, that it is a compound of two atoms of sulphur with six of oxygen. It is a colourless crystalline solid, which is tough and ductile, and can be moulded in the fingers like wax without injuring the skin. It liquefies at 65°, and boils at about 95°, forming a transparent vapour, if hot water be present. It unites with moisture when exposed to the air, and gives off dense white fumes. When thrown into water, the heat emitted is so great that it hisses as red-hot iron would do; and the solution has all the properties of ordinary sulphuric acid. It may be obtained by the distillation of fuming Nordhausen acid, when white fumes pass over in the cooled receiver and solidify into a white silky-looking fibrous mass. It may be also obtained by the distillation of acid sulphate of soda ($Na_2O.2SO_3$), after it has been deprived of its atom of water. It combines with sulphur, iodine, and hydrochloric acid; but both it and its compounds are objects of chemical interest rather than of practical value.

SULPHURIC ETHER is a term commonly but improperly applied to ethylic, vinic, or ordinary Ether (q. v.). True *sulphuric ether*, known also as *sulphate of ethyl* ($(C_2H_5)^2SO_4$), is an oily liquid of burning taste and ethereal odour, resembling that of peppermint, of specific gravity 1·120 (while that of ordinary pure ether is 0·720), and almost incapable of being distilled without decomposition, as at a temperature of about 280° it resolves itself into alcohol, sulphurous acid, and olefiant gas.

In the article ETHER, reference is made to the anæsthetic properties of that compound. Dr Richardson discovered in 1866 that local insensibility may be readily induced by the application to the skin of the finely divided spray of perfectly pure rectified ether, of specific gravity 0·723. The skin blanches in from half a minute to two minutes; and by following the knife with the spray, more than merely superficial incisions may be rendered painless. It has been successfully employed in numerous operations, including amputations of fingers and toes, removal of tumours and teeth, opening of abscesses, &c.

SULPHUROUS ACID. See SUPP. in Vol. X.

SU'LTAN, or SULTAUN, an Arabic word, signifying 'mighty man,' and evidently closely connected with the Hebrew word *shalal*, to rule, is in the East an ordinary title of Mohammedan princes. It is given, *par excellence*, to the supreme head of the Ottoman empire; but is looked upon as a less dignified title than that of Padishah (q. v.). It is applied in Egypt to the ruler of that country, and is also retained by the heir of the former reigning line of the Crim-Tartars. *Sultana* is the title of the wife of a sultan.

SULU ISLANDS, an archipelago of about 60 islands in the Mindoro Sea, between the Philippines and Borneo (q. v.). Cagayan Sulu, the chief of the islands, 36 miles long and 12 broad, contains the town of Soong, the residence of the sultan of the group. See PHILIPPINE ISLANDS.

SU'MACH (*Rhus*), a genus of small trees and shrubs, of the natural order *Anacardiaceæ;* having small inconspicuous flowers in panicles or in corymbs; a 5-parted calyx, 5 petals, springing from beneath a large orbicular disk; 5 stamens; a 1-celled germen with three stigmas; the fruit a small, nearly dry drupe, with bony *putamen.* The species are numerous, diffused over almost all parts of the world, except its coldest regions and Australia; and some of them, on account of peculiar principles which they contain, are of importance in the arts and in medicine; some are remarkable for their poisonous properties.—VENETIAN S. (*R. cotinus*), known also as Wig S. or Mist Tree, is a native of the south of Europe and west of Asia, and is often planted in America as an ornamental shrub. It has simple leaves, and hairy corymbs of fruit, which have a sort of resemblance to periwigs. The wood dyes yellow, and, with the addition of other substances, green and brown, and is known in trade by the name of *Young Fustic.* It is largely imported into the United States. The bark is sometimes used as a substitute for Peruvian Bark. The leaves are astringent, and are used in dyeing Turkey Red. The root is also used in dyeing, and the whole plant is used in Italy for tanning, and is there called *Scotina.* The seed resembles the almond in flavour. — The very acid fruit of the ELM-LEAVED S. (*R. coriaria*) — a native of the countries around the

Mediterranean, with pinnate leaves, not unfrequent in British shrubberies—has been used from the earliest times, as it still is by the Turks and Persians, as a condiment with different kinds of food. Both the seeds and the leaves are used medicinally, in the south of Europe and the East, as tonic and cooling. This species is also extensively

Sumach (*Rhus cotinus*), shewing leaves, flowers, and fruit.

used for tanning, particularly in Turkey and in Spain. The leaves and twigs are used for dyeing black, the roots and fruit for dyeing red, and the bark for dyeing yellow.—Similar to this in its properties and uses is the VIRGINIAN S., or STAG'S-HORN S. (*R. typhina*), a native of almost all parts of North America, and common in British shrubberies, which has the branches curiously crooked, and covered, when young, with a soft velvety down. It has pinnate leaves, with numerous leaflets.—The SMOOTH-LEAVED S. (*R. glabra*), a very similar species, also North American, has very acid leaves, which are eaten by children, and are used in domestic economy and in medicine on account of the malic acid which they contain. The bloom of the fruit is also very acid. This species is sometimes troublesome in North America, overrunning ground as a weed.—Of the acrid and poisonous species, the most important is the POISON OAK or POISON IVY (*R. toxicodendron*) of North America, a shrub with leaves of three leaflets, when erect 2 to 6 feet high, or climbing trees, when it is known as *R. radicans*, and reaching a length of 30 to 40 feet. The leaves are used in medicine in cases of paralysis, amaurosis, and other nervous affections, as a stimulant of the nervous system, also in chronic rheumatism, and obstinate eruptions; but are efficacious only when fresh, as the poisonous substance is volatile. Similar to this in properties are the POISON ALDER, or POISON S. (*R. venenata*), also known as POISON DOGWOOD, and other North American species, the juice of which is very acrid, and even the emanations are injurious to some persons, who, from remaining a short time near these plants, or from handling them, experience swelling of the whole body, with subsequent inflammation of the skin, pustules, and violent itching, whilst it is remarkable that others appear quite unsusceptible of their influence.—The VARNISH S., or JAPAN VARNISH TREE (*R. vernicifera*), a native of Japan and Nepaul, yields a varnish much used in Japan for lacquer-work. This varnish is the juice which flows from wounds in the tree, and which becomes thick and black by exposure to the air, but is still so transparent that the finest veins of wood varnished with it may be seen through it. It is sometimes mixed with colouring matters, sometimes with gold-leaf finely ground. The expressed oil of the seeds becomes as hard as tallow, and is used for candles.

The name TANNERS' S. is given to *Coriaria myrtifolia*, a shrub of the south of Europe, of the natural order *Ochnaceæ*. The leaves are astringent, and are used for tanning, and for dyeing black.

SUMA'TRA (called by the Arabians *Srimat* or *Srimata*, 'the happy,' whence its present name), the most westerly of the Sunda Islands, lies south of the Malay Peninsula, from which it is separated by the Strait of Malacca. Lat. between 5° 45′ N. and 5° 50′ S. It is 1040 miles long and 266 miles in extreme breadth; area, 168,000 sq. m.; pop., including that of the adjacent isles, 7,000,000, fully one half of whom were directly or indirectly under Netherlands rule until Nov. 1871, when these settlements were sold to Great Britain.

Physical Features.—The Barisan Mountains run throughout its entire length, varying in altitude from 1550 feet in the south-west to 6000 under the equator. Lofty cones, of which about 20 are volcanoes, attain to from 6000 to upwards of 10,000 feet. Another series of mountains runs parallel with the Barisan, lofty plateaux of great extent linking them together at various points. On the west coast, a few miles of low land lie between the mountains and the sea, in some parts spurs reaching the shore in beetling cliffs. Wide alluvial plains, covered with dense jungle and forest, through which the rivers run sluggishly, forming deltas at their mouths, stretch along the north-east coast; while the tidal action is eating into the west coast, new ground is forming on the east.

Extensive valleys lie between the mountain chains. Several beautiful lakes are scattered over the interior. The largest is Lake Singkarrah or Semaway, in Upper Padang, 17 miles long and 6 broad. It is 1167 feet above the sea, and discharges its waters by the Ombilin, which, flowing eastwards, becomes the Indragiri.

The mountain systems are of trachyte, granite, limestone, red sandstone, and a wide-spread conglomerate composed of granitic and quartzose particles, the hollows in many places being filled with lava. Sienite, porphyry, serpentine, jasper, basalt, and tufa occur. Tertiary deposits are found in the valleys, and in some parts of the coasts a rich vegetable mould rests on beds of red and grey clay, or on coralline limestone. Potter's clays are met with, and gold is widely diffused. Coal, iron-ore, copper, sulphur, lead, silver, saltpetre, alum, naphtha, &c., abound.

Rivers.—S. has many rivers, the most important being the Tūlang-Bawang; the Mūsi, or river of Palembang; the Djambi, Indragiri, and Siak, on the east; the Singkel, Tabūjong, Indrapūra, Moko Moko, Bencoolen, and Padang Gūtjie on the west. The capes and bays are numerous, the Bay of Tapanūli being capable of containing a large fleet. A chain of islands lies parallel to S. in the Indian Sea. The most important are—Babi or Si Malu, Nias (q. v.), the Batū Islands, North Pora, Coco Island, South Pora, North Pagei, and South Pagei. To the south-east lies Banca, rich in tin, producing also iron, lead, silver, copper, arsenic, and amber.

Climate.—The climate of S. is moderately healthy, especially on the east coast. In Tapanūli, however, are large marshes, inducing intermittent and typhoidal fevers, dysentery, and other diseases. A

slight increase of temperature takes place from October to March, the minimum being in May. Except in the highlands of the interior, where it is cool, the thermometer ranges from 70° F., at sunrise, to 94° at 2 P. M. The monsoons are irregular, and rain falls during all the months, though the quantity in October and December is double that in February and June.

Flora.—S. has many fine species of timber trees —as the Djati (*Tectona grandis*), the Maris, a hard and heavy wood, ebony, iron-wood, &c. The magnificent *Dryobalanops camphora*, and other resin-producing trees, are abundant. Several species of fig, the *Urceola elastica*, from which caoutchouc is obtained, and the gutta-percha tree (*Isonandra gutta*), are numerous. In the villages, the Bombax, or silk-cotton tree, forms a shady resting-place at noon. The lovely *Cinnamomum cassia*, the *Melaleuca leucadendron*, which yields the medicinal cajeput oil, the satin-wood (*Chloroxylon swietenia*), the gigantic reed (*Calamus draco*), from the ripe fruit of which the dragon-blood gum exudes, and a great variety of palms, form part of the botanical wealth of the island. Flowering plants and shrubs are numerous, and countless parasites garland the forest trees with flowers of every hue. The most curious of these is the *Rafflesia* (q. v.), which, clinging to the bark of large trees, spreads out the largest known flower, with a calyx 3 feet in diameter and 9 inches deep.

The fruits are richer in flavour than those of Java. Among these are the guava, citron, oranges, lemon, durian, mango, bread-fruit, cocoa-nut, pomegranate, water-melons, pine-apples, and the highly-prized mangosteen, or berry of *Garcinia mangostana*. Cacao, cotton, maize, indigo, tobacco, gambier, and more especially rice, millet, pepper, and coffee, are cultivated.

Fauna.—The elephant, single and double horned rhinoceros, tiger, leopard, black bear and tiger-cat, wild swine, tapirs, antelopes, deer, monkeys (including the ourang-outang), ant-eaters, many kinds of bat, &c., abound. Buffaloes, cows, goats, horses, sheep, and swine are kept by the natives. The peacock and the pheasants of S. are of rare beauty. Hippopotami and crocodiles frequent the rivers, which have many kinds of fish, including a species of salmon.

Geographical and Political Divisions.—The independent kingdom of Acheen extends from the north-west point to 97° 40′ E. long.; area, 2260 sq. m.; pop. variously given from 450,000 to 2,000,000; is well cultivated, and produces much pepper. Singkel, Tapanūli, and Lower Padang, until quite recently under the Netherlands residency of Padang, lie in succession to the south-east of Acheen. The interior, including the once-powerful kingdom of Menangkabou, is governed by the resident of Upper Padang. Bencoolen stretches along the west coast from 101° tc 104° 40′ E. long.; and the extreme south and the east coast, between 4° 4′—5° 56′ S. lat., form the Lampong districts. North of these is the residency of Palembang, with the kingdom of Djambi, which has been ruled over by a native prince under Dutch control. Farther north are Indragiri, Kampar, and Siak, governed as Djambi. Between Siak and Acheen are many petty states of little importance.

People.—The natives are chiefly Malays who profess Mohammedanism. In appearance, manners, and customs, however, the inhabitants of Acheen and the Lampongs differ widely from those of other parts. The Acheenese are tall, well-made, active, and intelligent, but cunning, proud, treacherous, and blood-thirsty. They live simply, but are slaves to opium. The Lampongers are of middle stature, well formed, of pleasant exterior, mild, but uncivilised and lazy. Caste prevails, and they follow the usages of their fathers, Mohammedanism being imperfectly known and practised. Polygamy obtains, the wives being bought from their relatives. The houses are on posts of iron-wood, several families living under the same roof. In other parts of S. the usual Malay type is found. The Kūbūs, in the north-west of Palembang, are probably the remains of the aborigines, a harmless race who live chiefly by the chase and fishing. Theft and murder are scarcely known among them. They believe in an after spirit-life.

Trade and Produce.—The imports and exports of the independent and half-independent kingdoms cannot be ascertained. Acheen alone produces 7000 tons of pepper annually, and also exports gold, precious stones, cotton, raw silk, sapan wood, benzoin, camphor, sulphur, betel, &c., to the west of India by way of Pūlū Penang and Singapore, receiving in return manufactured goods, salt, opium, &c. In 1862, the imports from Java amounted to £450,000; the exports to Java to £255,000. The trade direct with Europe and the countries of the East probably exceeds that with Java. Imports—rice, cotton and other textile fabrics, articles of taste, provisions, tobacco, &c.; exports—benzoin, gum elastic, resin, pepper, ratans, cotton, coffee, drugs, ivory, dye-stuffs, edible nests, wax, tobacco, bêche-de-mer, &c.

The rice-culture forms one of the chief sources of prosperity, the west coast producing 193,000 tons in 1862. The coffee yield amounted to 9322½ tons. Upper Padang sent the largest quantity of coffee and rice, with much cocoa-nut oil, to the market.

History.—Marco Polo visited S. in the 13th c., Alvaro Talezo in 1506, and Siquera in 1509, the Portuguese then entering into trading relations with the natives. About 90 years later, the Dutch under Houtman reached the island, and on a second visit he was treacherously murdered at Acheen. In 1601, two ships from Zeeland, with the Netherlands commissioners, General De Roi and Laurens Bikker, arrived, were favourably received by the king, obtained a full cargo, and returned with two Acheenese ambassadors. Later, the Dutch drove the Portuguese from their factory at Pūlū Tjinko, to the south of Padang; and in 1666, the latter place became the seat of the Netherlands power on the west coast. In 1795 Padang was taken by the British, and retained till 1819. A few years after, Bencoolen was also given up to the Dutch, and the southern division of the island soon fell under the same rule. Various rebellions against the Netherlands dominion have since arisen, with the uniform result of extending the power of the Dutch towards the interior and the north. In September 1865, an expedition was sent to force the king of Asahan, one of the small states on the north-east coast, to submit to their authority. In November, 1871, a convention was signed for the sale of the Dutch settlements in Sumatra by the representatives of the Dutch and English governments.—See *Flora van Nederlandsch Indie*, door F. A. W. Miquel (Amst. and Leip. 1855)

SUMBA'WA, one of the chain of islands to the east of Java, lies between 8° 4′—9° 2′ S. lat., and 116° 50′—119° 15′ E. long., is now divided into the kingdoms of Sumbawa, Bima, Dompo, and Sangar, each governed by its own sovereign. Area, 5838 square miles. Pop. nearly 100,000. The island is mountainous, but except the volcano Tambora, which is 9522 feet, the elevation does not exceed 5660. The most valuable timber-tree is the Djati (*Tectona grandis*, or Indian teak), and the tamarind is so abundant as to be little valued. Rice is extensively grown. Sapan-wood is contracted for with

the princes, by the Netherlands colonial government.

The natives of S. belong to the Malay race, but speak three different languages. They are inoffensive and industrious; murder, robbery, and theft being almost unknown. Many of them are Mohammedan, but the mountaineers are chiefly heathen, with an idea of a supreme being. Ancient relics recently found in Bima, indicate that they were formerly professors of Hinduism.

In 1815, an eruption of Tambora depopulated the kingdoms of Tambora and Papekat, 12,000 lives being lost, and great damage done to the whole island by the ashes. Another took place in 1836, and one of Gunong Api, in Bima, in 1860, but with little loss.

SU'MBUL (see MUSK PLANT) has been extensively employed for some years past, both in Great Britain and in America, in the treatment of epilepsy, hysteria, and other diseases of the nervous system. It has a musk-like odour, and an aromatic and somewhat bitter taste. It may be given in the form of infusion, tincture, or resin.

SU'MMARY DILIGENCE, in the practice of the law of Scotland, means issuing execution without the formality of an action, as a creditor enforcing payment of a bill of exchange or of a bond.

SUMMER, a horizontal beam, called also Breast Summer.

SUMMER DUCK, or WOOD DUCK (*Dendronessa sponsa*, or *Aix sponsa*), a very beautiful species of duck, of the section having the hind-toe destitute of membrane, a native of North America. It is found during the breeding season in almost all parts of the United States, and as far north as Nova

Summer Duck (*Dendronessa sponsa*).

Scotia, migrating southwards in winter, when it abounds in Texas and Mexico, but some remain during winter even in Massachusetts. It has been found capable of domestication.—Very similar to it is the MANDARIN DUCK (*Dendronessa* or *Aix galericulata*), a Chinese species. Both of these species have the power of perching on trees. The S. D. makes its nest in the hollow of a tree.

SUMMER ISLANDS, a small archipelago of islets off the west coast of Scotland, near the entrance of Loch Broom, an inlet in the north-west of the county of Ross. The islets are about 20 in number; and the largest of them, Tanera, two miles long, and a mile broad, and containing a pop. of 98, is the only one inhabited.

SU'MMONS, in English Law, means generally a writ directed to a party to appear and answer some complaint before a court or judge. It is the first writ in an action at law; and a similar writ issues incidentally both in Chancery and in interlocutory matters. It is also the first step in proceedings before justices.

SUMNER, CHARLES. See SUPP. in Vol. X.

SU'MPTUARY LAWS (Lat. *sumtus*, expense) laws passed to prevent extravagance in banquets, dress, and private expenditure. They abound in ancient legislation. The Locrian legislator, Zaleucus, 450 B. C., ordained that no woman should appear in the streets attended by more than one maid-servant, unless she were drunk, or wear gold or embroidered apparel, unless she designed to act unchastely. At an early period in Roman history, the Censors, to whom was intrusted the superintendence of public and private morality, punished with the *notatio censoria* all persons guilty of luxurious living, but as the love of luxury grew with the increase of wealth and foreign conquest, various legislative enactments were passed with the object of restraining it. The Lex Orchia, 161 B. C., limited the number of guests to be present at a feast; the Lex Fannia, 161 B. C., regulated the cost of entertainments, enacting that the utmost sum which should be expended on certain festivals was to be 100 asses, 30 asses on certain other festivals, and 10 asses on an ordinary entertainment, where also no other fowl than one hen was permitted to be served up, and that not fattened for the purpose. There were also the Lex Didia, Lucretia, Cornelia, Æmilia, Antia, Julia, and others, most of them passed in consequence of the practical disregard of the similar laws that had preceded them; but they all seem to have been habitually transgressed in the later times of the Republic.

Sumptuary laws were in great favour in the legislation of England from the time of Edward III. down to the Reformation. Statute 10 Edward III. c. 3, narrates, that 'through the excessive and over-many costly meats which the people of this realm have used more than elsewhere, many mischiefs have happened; for the great men by these excesses have been sore grieved, and the lesser people, who only endeavour to imitate the great ones in such sorts of meat, are much impoverished, whereby they are not able to aid themselves, nor their liege lord, in time of need, as they ought, and many other evils have happened as well to their souls as their bodies;' and enacts that no man, of whatever condition or estate, shall be allowed more than two courses at dinner or supper, or more than two kinds of food in each course, except on the principal festivals of the year, when three courses at the utmost are to be allowed. All who did not enjoy a free estate of £100 per annum were prohibited from wearing furs, skins, or silk, and the use of foreign cloth was allowed to the royal family alone. Act 37 Edward III. declares that the outrageous and excessive apparel of divers people against their estate and degree is the destruction and impoverishment of the land, and prescribes the apparel of the various classes into which it distributes the people; it goes no higher than knights, but there are minute regulations for the clothing of women and children. This statute, however, was repealed the next year. In France, there were sumptuary laws as old as Charlemagne, prohibiting or taxing the use of furs; but the first extensive attempt to restrict extravagance in dress was under Philip IV. By an edict of Charles VI., no one was allowed to exceed a soup and two dishes at dinner. Sumptuary laws continued to be introduced in England in the 16th, and in France as late as the 17th century. Scotland had also a similar class of statutes. The Scottish Parliament attempted to regulate the dress of the ladies, to save the purses of the 'puir gentlemen their husbands and fathers.' There was a prohibition against their

coming to kirk or market with the face muffled in a veil; and statutes were passed against superfluous banqueting, and the inordinate use of foreign spices 'brocht from the pairts beyond sea, and sauld at dear prices to monie folk that are very unabill to sustain that coaste.' Neither in England, Scotland, nor France do these laws appear to have been practically observed to any great extent: in fact, the kings of France and England contributed far more, by their love of pageantry, to excite a taste for luxury among their subjects, than by their ordinances to repress it. Mr Froude suggests that such statutes may have been regarded, at the time when they were issued, rather as authoritative declarations of what wise and good men considered right, than as laws to which obedience could be enforced. Enactments of this kind have long been considered to be opposed to the principles of political economy. Most of the English sumptuary laws were repealed by 1 James I. c. 25, but a few remained on the statute-book as late as 1856.

SU'MTER, Fort (originally spelled *Sumpter*, after General Sumpter, in whose honour it was named), an American fort of the second class, built 1845—1855, in the form of a truncated pentagon 50 feet high, on an artificial island, at the entrance of Charleston Harbour, two and a half miles distant from Forts Moultrie and Pinckney, on either side. On the secession of South Carolina, December 1860, Major Anderson, in command of the defences of the harbour, was called upon to surrender them to the state authorities. Instead of doing this, he abandoned the other forts, and occupied Fort S., mounting 52 guns, with a garrison of 70 men and 30 or 40 workmen. This was considered an act of war by the Confederates and their troops, who, under command of General Beauregard, took possession of Forts Pinckney and Moultrie, and erected additional batteries. While the surrender of the fort was under consideration, a fleet was sent from New York for its relief. On its appearance off the harbour, the attack on the fort was opened by General Beauregard, April 12, 1861, and it surrendered on the 13th. This event aroused the North, and began the war which terminated in 1865. During the siege of Charleston, this fort was battered by the heaviest artillery, until its walls were completely crushed and shattered. The flagstaff was shot away fifty times, and thousands of tons of iron projectiles were mingled with the débris of the fort; but the garrison constructed a still stronger fortress on its ruins, and held it for three years against assault and bombardment, until the operations of General Sherman compelled its evacuation, and the United States flag was again raised, April 14, 1865; an event soon followed by the evacuation of Richmond, and the surrender of all the Confederate armies.

SU'MY, a town of Russia, in the government of Kharkov, and 90 miles north-west of the town of that name, on the Psol. It contains several factories, and has an important annual fair. Pop. 3,811.

SUN, The, the great luminary upon which not only our well-being but our very existence depends, has been from the earliest ages a source of wonder and admiration, and its worship was probably the very first form of idolatry. See Sun-worship.

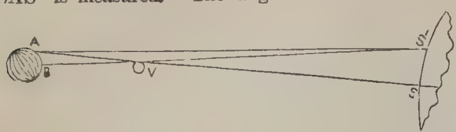
When the true system of the universe became known, one of the first labours of astronomers was to ascertain the distance and size of the sun, and these have been known for some time with tolerable precision; but until lately, the most vague and unsatisfactory theories regarding its chemical and physical constitution have continued to prevail.

Within the last few years, however, our knowledge of its chemical and physical constitution has increased with a rapidity probably unequalled in any other branch of science. This is due to the rigorous methods which in modern times are employed in every physical research, but chiefly to the fact, that the inquiries on the nature of the sun's body have been so fortunate as to gain recently two entirely new instruments of investigation of extraordinary power. These new instruments are, 1. *Spectrum analysis* (see Spectrum); and 2. *The application of Photography* (q. v.) *to record celestial phenomena.* Viewing the results which science has already obtained by means of spectrum analysis and celestial photography, and considering the shortness of the period in which these have been available, we hardly over-estimate their importance when we say that combined they will probably form a turning-point in the history of physical astronomy.

Our knowledge regarding the sun is best arranged under three heads: viz., *The general relations of the sun to our globe; the sun's chemical constitution;* and *its physical constitution.*

Relations of the Sun to the Earth, as the Source of Light and Heat.—In order to appreciate the grandeur of the scale on which solar activity is carried on, it is only necessary to know a few facts relative to the sun, which are best expressed by numbers. The *mean distance* of the sun from the earth, as recently estimated and corrected by Mr Stone from Le Verrier's determination of the solar parallax, is about 91,700,000 miles. The determination of this distance has always been considered the noblest problem in astronomy, chiefly because upon this measure depends every other measure of dimension in astronomy excepting those relating to the moon. The dimensions of the sun, and of every planet and satellite, and the distance of stars whose parallaxes are known, can none of them be determined without knowing our distance from the sun, and as the above recent determination gives the distance by nearly 3,500,000 of miles *less* than the hitherto received measure, it may be well to point out the probable cause of this discrepancy. We may here premise that the simple method of determining by direct observation the angle of Parallax (q. v.) on which the distance depends, although applicable to the moon, is impracticable in the case of the sun, owing chiefly to the circumstance that no stars can be seen in apparent contact with the sun's limb. The older determination of the sun's distance depended on observations of transits of Venus across the sun's disc in 1764 and 1769—mainly on those of the latter year. But the results almost entirely depended upon several fundamental facts and measurements, the accuracy of which, in the undeveloped state of astronomical observation during last century, could not be depended upon. Considering the wonderful accuracy which characterises modern astronomical research, it is now agreed among astronomers that this question will be best settled when another opportunity shall present itself to repeat the original investigation founded on transits of Venus. This will occur in 1874 and 1882; and it has been shewn by Mr Airy that the transit of 1882 will in every respect be particularly favourable for finally solving this problem. In proceeding to explain the method adopted for determining the sun's distance, it is assumed that the *relative* distances of the earth and the planet Venus from the sun are known, and that these are as 100 to 72. The orbits of both planets being approximately circular, when Venus is between the earth and the sun, her distance from the earth will therefore on this scale be expressed by 28. In the figure, let Venus (V) be so exactly between the sun and the earth that she can be seen upon the face

of the sun. An observer at A sees her upon the point S, and an observer at B sees her upon the point S′. The relation between S and S′ admits of accurate record, being observed in time, and converted into angular measure, and by means of this record the angle SAS′ is measured. The angle which we desire to



obtain in order to measure the sun's distance is AS′B. Now, the ratio of the measured angle SAS′ to the desired angle AS′B is sensibly the same as that of the distance of Venus from the sun to her distance from the earth, or as 72 : 28 very nearly, and thus we can calculate AS′B. It is the circumstance that we measure a large angle in order to infer from it a small one, which makes the transit of Venus the most favourable opportunity of all for obtaining an exact result. A transit of Mercury is inapplicable to the measure of the sun's distance, because the measured and required angles are here in the proportion of 4 to 6, that is, a small angle is measured to obtain a larger one, which is unfavourable to accuracy.

The other important numerical facts relative to the sun are the following: Its *diameter* is 850,100 miles, or more than 108 times the mean diameter of the earth; it is also nearly twice as great as that of the moon's orbit around the earth, so that if the earth were placed in the centre of the sun, the moon revolving round the earth would still be at a depth within the sun of more than 187,000 miles from its surface. The *volume* or bulk of the sun exceeds that of the earth 1,273,000 times, and is 600 times greater than the bulk of all planets at present known, together. The *mass* of the sun, or quantity of matter it contains as measured by weight, exceeds that of the earth 325,000 times, and is 704 times greater than the masses of all known planets put together. The *period of rotation* of the sun upon its axis, discovered by Fabricius and Galileo, and by the latter first calculated from observations of the sun-spots, and which takes place in the same direction as that of the earth, is about 25 days 8 hours. It appears, however, from the investigations of Mr. Carrington, recently published, that this period varies according to the solar latitude of the spots from which it is calculated. The *inclination* of the axis of the sun to the ecliptic is about $7\frac{1}{4}^\circ$, and the *longitude of the ascending node* is about 74° 40′ (1850).

The form or *figure of the sun* has been the subject of very recent investigations. The polar and equatorial diameters of the sun's disc as observed, have been supposed to differ, though by a very small quantity only. The observations of Maskelyne and Littrow make the polar diameter greater than the equatorial, while Carlini and Bianchi arrive at the opposite result. Observations of equal excellence, and calculations of equal accuracy, giving these opposed results, it would seem a satisfactory conclusion, borne out by other additional facts, that the figure of the disc is a true circle. Nevertheless, doubts have been lately raised as to the true figure of the sun, and it has been proposed to devise an apparatus for the purpose of examining whether the sun's disc is really circular. The Greenwich observations, made from the year 1836 to the present time, give a horizontal diameter exceeding the vertical only by 0″·1, that is, by the $\frac{1}{19230}$th part of the entire angular or apparent diameter of the sun, and although the Astronomer-royal is correct in saying that this is 'a quantity smaller than we can answer for in these or in any other methods of observation,' there remains still the fact, that the photographs of the sun do not quite agree in the amount of the value for the diameter with that given by observations.

The general laws by which the relation of our earth to the sun, as the source of light and heat, is governed, are of the most simple kind. The rays which emanate from the sun's disc into space, proceed in diverging lines, and on arriving at the earth, their intensity will be inversely proportional to the square of the sun's distance. This may be called the primary law; but the more obvious phenomena of solar heat and light are manifested to us under a secondary law, relative to the inclination of the surface at any given place and time to the direction of the rays. This law is, that the sun's intensity is less in proportion as his rays fall more obliquely; or more exactly, that it varies as the sine of his altitude. But besides this simple law, numerous causes are at work disturbing its operations, and producing the complicated phenomena which form the subject of meteorology. Captain John Ericsson, the distinguished inventor of the caloric engine, has proposed to utilize the sun's heat by means of a solar engine, which he asserts is essentially a modern steam-engine using to the fullest extent the mechanical energy of the sun's concentrated rays. His papers, descriptive of the dynamical value of the sun's heat, may be seen in the *London Engineering Journal*. See CLIMATE, EARTH, TEMPERATURE, &c.

Chemical Constitution of the Sun.—Astronomy long since weighed and measured the sun, and in our days, chemistry, aided by physics, has made an analysis of it. It tells us this: 'The solar atmosphere comprises, in the state of vapour, a great number of the substances which compose our planet; of the metals which enter into the composition of our alkalies and earths, it has *sodium*, *magnesium*, *calcium*; it also contains *iron*, *zinc*, *copper*, *nickel*, *chromium*, and *hydrogen*. On the other hand, neither gold, platinum, silver, mercury, tin, aluminium, lead, antimony, arsenic, nor silicon, at least in notable quantities, have as yet been found in it.' These affirmations are sufficiently surprising, when we consider that the body to be analysed is many millions of miles withdrawn from all chemical manipulations, tests, reagents, and the usual appliances of chemical research. For the way in which the facts have, step by step, been established, we must refer to the article SPECTRUM.

A recent extension of Prevost's theory of exchanges, due chiefly to the labours of Provostaye, Stewart, and Kirchhoff, informs us that a substance, when comparatively cold, absorbs the very same rays which it gives out when heated. Hence it was inferred by Kirchhoff, that if there were sodium or iron in a comparatively cold state in the solar atmosphere, above the source of light, these substances would produce black lines corresponding in spectral position with the bright lines which they give out when heated. It is only necessary to state, that from this law at once we have a proof, from the coincidence between dark and bright lines observed by Kirchhoff, that a large number of the absorption lines in the sun's light are caused by the presence in the sun's atmosphere, in a comparatively cold state, of the vapour of various familiar substances, and that the assertion with which we commenced this division of our subject is strictly proved.

Physical Constitution of the Sun.—What spectrum analysis is for an investigation into the chemical constitution of the sun, the new art of celestial photography is for the final determination of its physical state. Since the first discovery by Fabricius

of those remarkable phenomena on the sun called *sun-spots*, an immense variety of theories, as to the probable constitution of the solar body, has been brought forward by nearly every observer; but the fleeting and transient nature of these phenomena has often raised into theories momentary impressions, which in a great many cases have proved to be in opposition to established physical laws. Solar photography will probably best enable us to solve the mystery that still surrounds this question, not only by presenting the objects to an optical scrutiny, under circumstances more advantageous than those which attend telescopic examination, but chiefly because it enables us to keep a permanent record of passing phenomena, ready at any time for deliberate measurement and comparison, from which alone the general laws will ultimately be derived.

One of the most important discoveries in connection with sun-spots, science owes to Dr Alexander Wilson of Glasgow, who, in the year 1769, observed certain general and remarkable features of sun-spots, which enabled him to establish the significance of these phenomena for a solution of the question as to the sun's physical constitution. These features are as follows: When a spot was near the middle of the sun, it was found to consist of a dark *central* part, called the *nucleus* or *umbra*, and *around this* was a comparatively brighter envelope, called the *penumbra*, and at such a time both parts were distinctly visible. But as the spot approached one border, the penumbra on the side nearest the observer became gradually more and more foreshortened, while the penumbra on the other side grew broader and broader, and at length, as the spot was disappearing, that is, passing the edge of the limb, the near side of the penumbra, as well as the dark central part, entirely vanished, nothing remaining except the opposite penumbra. When a spot made its appearance on the other side of the border, Wilson noticed the same phenomena in an opposite order, and soon discovered that they were nearly universal. It followed from these observations at once, that every spot presents the appearance of a funnel-shaped opening in the sun's body, which by the rotation of the latter, successively presented the described appearances. These observations have been abundantly confirmed by Messrs De la Rue, Stewart, and Loewy.

An accurate and laborious investigation by Hofrath Schwabe must next be mentioned. He has shewn, as the result of nearly forty years' observations, that the number of groups of sun-spots is not the same from year to year, but has a maximum about every ten years; and General Sabine has recorded the wonderful fact, that the various epochs of maximum spot-frequency are also those of maximum disturbance of our earth's magnetism. It has been more recently shewn that they are in some way influenced by the planets Venus, Mercury, and the Earth.

It was next shewn by Carrington that sun-spots have a proper motion of their own—those near the solar equator moving faster than those near the poles.

While spots are darker than the general surface of the sun, there are also frequently observed patches brighter than the general surface. These are called *faculæ*, and they generally accompany spots, most frequently in their wake; but they are only distinctly visible near the sun's limb, and lose their specific luminosity near the centre of the sun's disc.

But there is another phenomenon connected with our luminary not less remarkable than sun-spots. This is the red flames, or *protuberances*, which surround the sun's disc on the occasion of a total eclipse. These remarkable appearances have lately been proved by Mr De la Rue to belong to the sun. Zöllner has observed the red eruptive flames or protuberances very distinctly, and compares them to cumulus clouds with occasional eruptions resembling those of volcanoes or hot springs, while flashes like electrical discharges extended across the field of his spectroscope, indicating the presence of intensely ignited bodies moving near the sun's surface. The whole photosphere of the sun appears to consist of separate luminous patches of a wonderful uniformity of size and shape, which have been denominated 'willow leaves,' from their resemblance to these in figure.

From these and the following phenomena astronomers have concluded that the sun possesses a very extensive atmosphere, colder than the source from which the light emanates. 1. In all photographic pictures of the sun the centre of the disc is brighter than the border, as if the oblique rays from the border had to pass through a greater extent of a comparatively cold absorbing atmosphere. 2. Kirchhoff's discovery leads to the same conclusion, since it implies the presence in the sun's atmosphere of a number of substances in a comparatively cold state. 3. The red flames seen during a total eclipse indicate the extension of matter around the sun to a distance of at least 72,000 miles above the photosphere; and the nature of the light given out by these red flames is that which characterizes gaseous matter in a heated state.

If a spot be hollow, as we have reason to suppose, it is only necessary to believe that there has been a descending current of this cold absorbing atmosphere to account for the want of luminosity. In like manner, on this hypothesis, a facula will be a portion of the luminous matter which has been removed high up into the atmosphere, and which thus escapes, more especially near the borders (where it shines out brightly), the absorbing influence of the atmosphere. A spot may thus be supposed to be produced by two currents—one ascending, and carrying the hot luminous matter up; the other descending, and carrying the cold atmosphere down. The hot luminous matter, being carried up into a region of greater velocity of rotation, will fall behind; and this may account for faculæ being generally in the wake of spots. On the other hand, the cold matter coming down will be carried forward; and this may account for the proper motion of spots observed by Carrington.

During the solar eclipse of August 17, 1868, in India, the observers agreed that the protuberances * are gaseous in their nature, and consist of heated hydrogen, and probably sodium and other terrestrial elements. The eclipse of 1869 was successfully observed by numerous parties skilled in the use of astronomical, spectroscopic, and photographic manipulation at Sitka, and from Sioux Falls, Dakota, to Cincinnati. During this eclipse the phenomena of the corona and the numerous bright red protuberances projected beyond the black disc of the moon attracted attention, and the latter are now believed to be mainly a mass of incandescent hydrogen, reaching to the height of 50,000 to 100,000 miles. The eclipse of 1870 was observed by American astronomers successfully in Spain, and Prof. Peirce reported the true corona to be a solar atmosphere, extending 80,000 miles above the ordinarily visible surface of the sun. This was shown by three distinct sources of proof, one of which was, the spectrum observations of Prof. Young, of Dartmouth College, N. H., which confirm Secchi's discovery of a continuous spectrum at the edge of the sun, and render tenable the theory of Kirchhoff as to the sun's constitution. The corona was shewn by the English observers in Sicily to be radially polarised, and therefore to radiate while it reflects solar heat to us. As respects the chromosphere beyond the pho-

* For a series of remarkable illustrations of solar protuberances, see plate in *Am. Journ. of Science* Vol. I. April 1871.

tosphere, it is suggested by Lockyer that it extends some 5′ or 6′ from the sun, and is built up of layers of vapour of different densities.

Until very lately, when the theory of the conservation of energy became understood, the vaguest ideas regarding the probable origin of the sun's light and heat had been entertained. We are now led to think that as the particles which formed the sun have gradually come together under the influence of gravitation, the result has been the conversion of potential energy into motion, or kinetic energy, and of the latter into heat. This idea is, we believe, also entertained generally by those who have studied the subject and are at the same time acquainted with the theory of the conservation of energy. See *The Sun*, by Amédée Guillemin, London, 1870.

SUN AND FIRE WORSHIP. All investigation tends to shew that nature-worship was the basis of all polytheistic religions, and that the chief deities of the several mythologies were originally personifications of the sun, or of particular influences of the sun. The original solar nature of Jupiter, Zeus, Odin, Baal, Amen Ra (see EGYPT), Indra, &c., can hardly be mistaken. See those heads; also SCANDINAVIAN MYTHOLOGY, PHŒNICIA; and for a full development of the subject, Max Müller's essay on *Comparative Mythology* (Oxford Essays, 1856). The actual sun, however, still continued an object of worship, more especially as in the abstract and more strictly personal gods, moral and intellectual attributes came to predominate over and obscure the physical (see HELIOS), and with the worship of the sun was more or less closely associated that of fire—his representative on earth. See PARSEES, NEED-FIRE, BELTEIN.

The most complete system of sun-worship that we have any account of is that existing in Peru when discovered by the Spaniards (1526). 'Our northern natures can hardly comprehend how the sun, and the moon, and the stars were imaged in the heart of a Peruvian, and dwelt there; how the changes in these luminaries were combined with all his feelings and his fortunes; how the dawn was hope to him; how the fierce mid-day brightness was power to him; how the declining sun was death to him; and how the new morning was a resurrection to him: nay, more, how the sun, and the moon, and the stars were his personal friends, as well as his deities; how he held communion with them, and thought that they regarded every act and word; how, in his solitude, he fondly imagined that they sympathised with him; and how, with outstretched arms, he appealed to them against their own unkindness, or against the injustice of his fellow-man.'—Helps's *Spanish Conquest of America*. The Incas, as the Peruvian monarchs were called, claimed to be children of the sun, and his representatives on earth. Their government was a despotic theocracy, of which the Inca was both high-priest and king. In Cuzco, the capital, stood a splendid temple to the sun, all the implements of which were of gold. On the west end of the interior was a representation of the sun's disc and rays in solid gold, so placed that the rising sun, shining in at the open east end, fell full upon the image, and was reflected with dazzling splendour. In the place or square of the temple, a great annual festival was held at the summer solstice. The multitude, assembled from all parts of the empire, and presided over by the Inca, awaited in breathless solemnity the first rays of their deity to strike the golden image in the temple, when the whole prostrated themselves in adoration. Sacrifices, similar to those of the Jews, were offered on the occasion, and bread and wine were partaken of in a manner strikingly resembling the Christian communion.

'It must not be supposed that the sun alone absorbed the devotion of the Peruvians. There was little in nature that they did not contrive to make a deity of. The Moon, as the spouse of the Sun, the planet Venus as his page, the Pleiades, and the remarkable constellation of the Southern Cross, were minor deities. The rainbow and lightning were also worshipped as servants of the Sun; and fire, air, earth, and water were not without adoration.'

S'UNAH'S'EPHA is, in the ancient legends of India, the son of a poor Brahman, Ajîgarta, who was sold by his father for 100 cows to *Haris'chandra* (q. v.), and offered by the latter as a victim to Varun'a, instead of his own son Rohita, whom he had pledged himself to sacrifice to this god. The legend relates that when S. was bound to the sacrificial post by his own father—for no priest could be found to perform the ceremony—and when his father came whetting his sword to kill him—for neither was any priest to be found who would perform such a sacrifice—S. prayed in succession to the gods Prajâpati, Agni, Savitr'i, Varun'a, again to Agni, then to the Vis'we-Devâh', Indra, the As'wins, and the Dawn; and while he praised the Dawn with three verses, at the delivery of each verse his fetters became looser, and when the last verse was said, he became free again. He left afterwards the family of his parents, and was adopted by *Vis'wâmitra*, under the name of S'unah's'epha Devarâta (the God-given). The *Aitareya Brâhman'a* (see VEDA), where this legend is related, also ascribes to him the first performance of some Vedic ceremony.

SU'NART, LOCH, an inlet of the sea in the extreme west of Argyleshire, Scotland, having the districts of Ardnamurchan and Sunart on the N., and that of Morven on the S.; length, inland from the Sound of Mull, 19 miles; breadth varies from 3 miles to 3 furlongs. At its head stands the village of Strontian.

SUNBIRDS (*Cinnyridæ*), a family of birds of the order *Insessores*, and tribe *Tenuirostres*, which may be regarded as a connecting link between the

Sunbird (*Nectarinia phœnicura*).

Creepers and the Humming-birds, and as occupying nearly the same place in the tropical parts of the Old World which belongs to the humming-birds in America. They are all of small size, although none are so small as the smallest humming-birds; they rival humming-birds in brilliancy of plumage, and

like them they feed on the juices of flowers, which they suck by their long bill; they do not, however, flutter on the wing when feeding, like humming-birds, but perch on or beside the flower. The species are very numerous, and are natives of the southern parts of Asia, the Eastern Archipelago, and Africa. The resplendent metallic plumage belongs only to the male, and only to the breeding season.

SU'NDA ISLANDS, that great chain of islands belonging to Malaysia, running east, commencing with Sumatra (q. v.), and ending with Timor (q. v.), and separating the Java Sea from the Indian Ocean. Sunda Strait is a passage, from 70 to 90 miles in breadth, between Sumatra and Java.

SU'NDAY. See SABBATH; LORD'S DAY; PUBLIC-HOUSES.

SUNDAY SCHOOLS. The origin of Sunday schools is popularly ascribed to Robert Raikes, of Gloucester, in 1781. His claims may, however, be fairly contested by Ludwig Hecker, of Ephrata, Pennsylvania, who, about 1739, commenced 'Sabbath schools' for the poorer classes around him. Raikes, seeing a group of children, miserably ragged, at play, was informed that 'on Sunday the street was filled with a multitude of wretches, who, having no employment on that day, spent their time in noise and riot, playing at chuck, and cursing and swearing.' To check this deplorable profanation of the Lord's Day, he engaged four women, who kept dame schools, to instruct as many children as he should send them on the Sunday, in reading and the church catechism, for which they were to receive one shilling each. In a short period, a visible improvement was effected both in the manners and morals of the children, who came in considerable numbers; they attended church with their mistresses, and a great many learned to read and say their catechism. Such was the origin of the Sunday schools. This excellent scheme was noticed in the Gloucester newspaper in 1783; but a letter of Mr Raikes, from which the above account is taken, published in the *Gentleman's Magazine* in 1784, first drew general attention to it. Numerous schools, formed on the same model, sprang up in all the principal towns; and a society, under high patronage, was formed in London in 1785 for the establishment and support of Sunday schools throughout the kingdom, which in fourteen years expended £4000 in payment of teachers. Her Majesty, Queen Charlotte, admitted Mr Raikes to an audience, and expressed her high approbation of his plan. This was the first stage of the Sunday school. The great impediment to its prosperity was the expense of hiring so many teachers. Even in Gloucester, the birthplace of the Sunday schools, after Mr Raikes's death in 1811, all the Sunday schools were closed for a time owing to want of funds. Whoever first conceived the idea of gratuitous instruction, has nearly as great merit as Mr Raikes himself; but probably it was suggested by necessity to many minds in different places at the same time. It was the means of starting Sunday schools on a new career of success, and the idea spread so rapidly, that, by the year 1800, the teaching was almost universally gratuitous. A higher class of teachers offered their services; the schools ceased to be filled by the very poorest alone; handsome buildings were erected in connection with the different churches and chapels, or by general subscription, and that system was organised which has covered the land with schools. The secular teaching, which in certain instances included writing and arithmetic, was not of a very high order; but it placed the key of knowledge in the hands of multitudes who would otherwise have been unable to read and the religious instruction with which it was combined has moulded the character of some of the best men in England. In 1803, the Sunday School Union was formed, which, by its numerous publications, its travelling agents, and its connection with branch societies in every part of the kingdom, has exercised great influence on the Sunday school cause. The Institute of the Church of England, which operates in a similar manner, is of later date. Within the last few years, the Sunday school has entered upon a third stage of its history. The improvement and multiplication of week-day schools obviate the necessity for teaching reading in Sunday schools, so that they are gradually becoming restricted to religious instruction. This may for a time affect their popularity, but as the teachers are earnest men, are cultivating the art of teaching with considerable success, and as Sunday schools have prospered in Scotland, where religious teaching alone has prevailed, there is no reason to fear their stability.

The Sunday school found its way into Scotland as early as the year 1782; but it was not till 1786, when the Society for promoting Religious Knowledge among the Poor was formed, that it was publicly recognised; nor till 1797, when the Gratis Sunday School Society was originated, that schools became general. At first, they met with considerable opposition from portions of the ecclesiastical courts, but they are now supported by all the churches. Sunday School Unions exist in Edinburgh, Glasgow, and most of the large towns. The names of Dr Chalmers, James Gall, the author of the *Lesson System*, and David Stowe, the author of the *Training System*, deserve mention in connection with the progress of Sunday schools in Scotland. In Ireland, Sunday schools had been partially anticipated in County Down in 1770; but it was not till 1785 that the system pursued by Mr Raikes was adopted, since which, its history has been analogous to that of England. The Sunday School Society for Ireland was established in 1809. Sunday schools were introduced into New York in 1816, through the exertions of some benevolent ladies, from which they have spread themselves through the United States. They are now to be found wherever the English tongue is spoken. They thrive vigorously in the Protestant churches of France; and more recently have been planted in parts of Germany and Italy. The Roman Catholics, in this country at least, have numerous Sunday schools. Of the numbers of teachers and scholars who are weekly assembled in the schools throughout the world, no estimate can be formed; but it is stated on good authority that there are in the United Kingdom about 300,000 teachers and 3,000,000 scholars.

SU'NDERBUNDS, a tract of British India, presidency of Bengal, consists of a number of low islands, forming the delta of the Ganges. The tract extends east from the mouth of the Hoogly to the island Rabanabad, is 158 miles long, 75 miles broad, has an area of 6500 sq. m., and an inconsiderable population. The islands are separated from each other by narrow channels, through which the waters of the Ganges force their way to the sea. The chief channels (14 in number) are navigable for the largest craft used in inland navigation. In such of the islands as have not been cleared, luxuriant woods abound, and afford lairs for the tiger, wild boar, and other ferocious animals. Government have commenced vigorous operations for the clearing of the islands, and grants of land are offered to settlers at a nominal rate. The climate, though improving, and capable of further improvement, is, as might be expected, very unhealthy. Rice, sugar, and indigo are produced in the cleared districts.

Large quantities of fish, obtained in the waters of the S., are sent to Calcutta. Large and fierce alligators abound in the channels.

SUNDERLAND, a thriving municipal and parliamentary borough and seaport, in the county of Durham, 13 miles north-east of the city of that name, at the mouth of the Wear. The town may be said to be co-extensive with the parliamentary borough, and to include the suburbs of Bishop-Wearmouth on the south bank, and Monk-Wearmouth and Southwick on the north bank of the river, connected with S. proper by an iron bridge of one arch, 236 feet long, and nearly 100 feet above the river at low water. The bridge over the Wear was erected in 1796, but was repaired and widened in 1858 by Robert Stephenson (q. v.), at the cost of about £40,000. On both sides of the river there are extensive wet docks, much of the area of which has been reclaimed from the sea. The harbour, which is defended by batteries, is formed by two great piers, one 650 yards and the other 590 yards in length; and the port is resorted to by vessels of the largest tonnage, from all commercial countries. In 1872, 2456 vessels, of 698,224 tons, entered, and 2986, of 868,329 tons, cleared the port. In the same year 3,482,860 tons of coal were exported. After Newcastle, Sunderland is probably the largest coal-shipping port in the world. Ship-building is one of the principal branches of industry. Glass, earthenware, ropes, and chains, anchors, and other iron-wares, are very extensively manufactured. Coals, lime, grindstones obtained from quarries in the neighbourhood, together with the manufactures, are exported. The public park of S., about 70 acres in extent, is adorned with a bronze statue of General Sir Henry Havelock, a native of the town, and commands a fine view of the sea. The village of Roker, a mile from the town, is much resorted to for sea-bathing. Fishing is carried on to a considerable extent. Pop. of parliamentary borough, which returns two members to the House of Commons (1851), 67,394; (1881), 124,960; of municipal borough (1881), 116,262.

SUNDERLAND, ROBERT SPENCER, second Earl, was the only son of HENRY, first earl, who had been raised to the peerage in 1643, for his exertions in the royal cause. He was born in 1642, and after serving as ambassador to several courts, became in 1679 Secretary of State. He had by this time manifested remarkable talent. Bishop Burnet says of him: 'He had a superior genius to all the men of business that I have yet known.' At first, he united with Essex and Halifax in opposing Shaftesbury, who wished to set Monmouth on the throne, and favoured the exclusion of the Duke of York. He encouraged the king to persevere in the degrading French alliance, and, with the Duchess of Portsmouth, to whom he attached himself, negotiated a treaty by which, in consideration of an annual pension from the French king, Charles was to agree to assemble no parliament for three years. Before the end of the year, he had shaken off Essex and Halifax; and a new triumvirate, consisting of himself, Lord Hyde, and Godolphin, succeeded to the confidence of Charles II. The treaty with France was broken off, and S., who was now afraid of the Whigs, engaged the king in a more popular alliance with Spain. After the dissolution of the last of the exclusion parliaments, he lost his office; but the duchess remained faithful to him in disgrace; and by her influence, and that of Lord Rochester, he was, in 1682, says Bishop Burnet, 'upon great submission made to the Duke [of York], again restored to be Secretary.' He remained in office until the accession of James II., when his influence in the ministry became greater than ever. He who had so often saved himself in the former reign by the influence of the Duchess of Portsmouth, now secured himself another patroness in the king's second wife, the Princess of Modena. Although there is reason to believe he gave some encouragement to Monmouth in his rebellion, he managed, with consummate art, to obtain the entire confidence of James, and in 1685 became prime minister. He was intrusted with a knowledge of the king's intention to establish the Roman Catholic religion as the national church, and was indeed the only minister in whom the king confided. In 1687, he privately conformed to the Roman Catholic Church, and afterwards openly professed his conversion. His influence was so great, that James would grant no favour until he had asked the question: 'Have they spoken to Sunderland?' and when told that this nobleman got all the money of the court, he would reply: 'He deserves it.' Yet we find him about this time in correspondence with the Prince of Orange, afterwards William III. The Princess Anne described S. as 'the subtillest workingest villain that is on the face of the earth.' Burnet says he entered into a particular confidence with the Prince of Orange, which he managed by his uncle, Mr Sidney, who was sent envoy to Holland. With profligate but masterly dexterity, he contrived to deceive both his master and Barillon, and to keep them in ignorance of the events that were passing in Holland. When the Prince arrived in England, S. and his wife went to Amsterdam, whence he wrote to the new monarch, claiming his favour and protection on the ground that he had all along been in his interest. In 1691, he was allowed to return to England, and to kiss the king's hand. In 1695, William III. spent a week at S.'s house at Althorpe. It was imputed to him that he had changed his religion, in the late reign, in order the more effectually to ruin King James; and it was generally believed that he had rendered King William, when Prince of Orange, some signal services, which no one else could have done. This belief gained credit from the favour shewn him by William. He was made Lord Chamberlain, and as such took his seat at the head of the council table. After directing affairs as the acknowledged head of the government, he resigned office in 1697, and retired to private life. He spent the rest of his days at Althorpe, where he died in 1702. He never shone as a public speaker. He had, however, unusual abilities for business, and a rare skill in the art of insinuation. He possessed exquisite courtly talent, extraordinary versatility, and a flexibility of principle too common in his day, but carried by him to the most reprehensible lengths. By his wife, Anne, daughter of the second Earl of Bristol, he left CHARLES SPENCER, third earl, who was born in 1674. He was described by Evelyn as a youth of extraordinary hopes, very learned for his age, and ingenious. He was for some time Secretary of State in the reign of Queen Anne, and under George I. rose to be all-powerful; but in 1721, being accused of receiving £50,000 worth of the fictitious stock distributed by the directors of the South Sea Scheme (q. v.), in order to bribe the government, he was acquitted only by an inconsiderable majority and that from party considerations, and the indignation of the public made him resign his office. He died in 1722, not without suspicion of having intrigued, after his fall, for the restoration of the Tories, if not for the return of the Pretender. S. was a type of the political morality, or rather immorality, of a disgraceful age, when the greatest statesmen made no scruple of sacrificing either their own party, or the interests and dignity of the nation to personal

ambition. His title descended to CHARLES, his second son, who succeeding, 1733, to the honours of his illustrious grandfather, John Churchill, the earldom of Sunderland became absorbed in the dukedom of Marlborough. His third son, JOHN, was ancestor of the Earls Spencer.

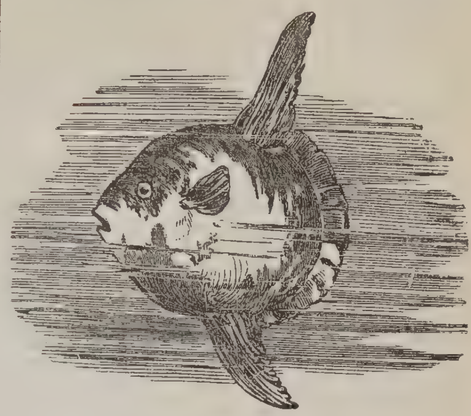
SU'NDEW (*Drosera*), a beautiful and interesting genus of plants of the natural order *Droseraceæ*, several species of which are natives of the U. States, found in bogs and moist healthy ground. The most common is the ROUND-LEAVED S. (*D. rotundifolia*), which is found in almost all places suitable to

Sundew (*Drosera rotundifolia*).

the plant. The leaves all spring from the root, and spread out in a rosette, from the centre of which springs the flower-stem or scape, with a raceme of flowers all on one side. The leaves of this and the other species are fringed and beset in all parts with hairs, which bear at their extremity viscid glands, and the irritation of these glands causes them to contract and fold up, so that insects are imprisoned by them. The whole plant is acrid, curdles milk, and has a reputation for removing corns, bunions, and warts. An agreeable liqueur, called *Rossoli* (*Ros Solis*) is made by infusing four handfuls of the plant in two quarts of brandy, and adding a pound and a half of finely powdered sugar, a pint and a half of milk, and an ounce of powdered cinnamon, straining through a cloth, and adding two grains of musk, and half an ounce of sugar-candy.

SUN-DIAL. See DIAL.

SU'NFISH (*Orthagoriscus*), a genus of fishes of the order *Plectognathi* (see DIODON), having the body compressed, and not capable of inflation, as in the other *Diodontidæ;* abruptly terminating in a very short tail; the dorsal and anal fins long and pointed, united to the short tail-fin; each jaw furnished with a cutting edge of bone instead of teeth. The species chiefly inhabit the seas of warm climates, but two are occasionally seen on the coasts of Britain. The SHORT S. (*O. mola*), when young, is almost perfectly round, but becomes rather more elongated when full grown. The name S. is variously regarded as derived from the form of the fish, and from its habit of floating at the surface of the water, in fine weather, as if to enjoy the sunshine. It attains a large size, being sometimes five or six feet in length, and is harpooned by sailors. Its flesh is white and well flavoured, somewhat resembling that of the skate. The liver yields a large quantity of oil, which is in repute among sailors as an external application for the cure of sprains, rheumatism, &c. The OBLONG S. (*O. oblongus*), of which specimens have also been taken



Sunfish (*Orthagoriscus mola*).

on the British coasts, but more rarely, is of a longer form. It also attains a large size. The Sunfishes feed upon sea-weeds.

SU'NFLOWER (*Helianthus*), a genus of plants of the natural order *Compositæ*, suborder *Corymbiferæ*, having large flowers; the florets of the ray strap-shaped, without stamens or pistils, yellow or orange; the florets of the disc tubular, perfect, yellow or purplish brown; the flowers solitary or in corymbs, with an involucre of numerous leaves; the fruit compressed, with a pappus of two or more deciduous scales. The species are numerous, all natives of America; large herbaceous plants, with opposite or sometimes alternate undivided leaves. The ANNUAL S. (*H. annuus*), common in our flower-gardens, is a native of tropical America, where it

Sunflower (***Helianthus annuus***).

sometimes attains a height of twenty feet. The stem is thick and rough; the flowers solitary, and from one foot to two feet in diameter, nodding; the leaves heart-shaped-ovate. This plant is now cultivated in almost all parts of the world, and in the south of Europe is sometimes a field-crop; the seeds being valued as food for cattle and poultry, and on account of the oil which they yield, which

is little inferior to olive oil. An acre of good land produces about fifty bushels of seed, each bushel yielding a gallon of oil. The seeds are also used like almonds for making demulcent and soothing emulsions; and in some parts of Europe, a bouilli is made of them, which is used as food for infants. The American Indians make bread of them. The flowers abound in honey, and are much frequented by bees. The leaves are good fodder for cattle. The stems are used for fuel, and yield much potash. —The Jerusalem Artichoke (q. v.) belongs to this genus.

SUNN (*Crotalaria* [q. v.] *juncea*), a leguminous plant, native of India, which has been in general cultivation there from time immemorial, for the fibre of its bark. It has a strong general resemblance to Spanish Broom. It is, however, an annual plant. The plant is cultivated not only for its fibre, but as food for milch-cows. The seed is generally sown in April or May, and in August it is pulled, or cut close to the ground —when grown for its fibre—laid in long rows till the leaves begin to rot and separate from the stalks, and steeped in water for a few days, till the bark separates freely. The fibre is not so strong as hemp; but good cables, canvas, and cloth are made of it. It is now imported in considerable quantity into Britain. It is known by various names. *Taag* is one of its Indian names, and it is sometimes called *Brown Hemp*, *Bengal Hemp*, &c. The confusion of names makes it difficult to ascertain the quantity imported.

SU'NNA (Arab. custom, legal usage), originally denotes among Muslims the sayings and the example of Mohammed and his community, provided they are in accordance with the Koran, the meaning of which, however, is itself explained by the Sunna. The term is therefore (though incorrectly) used for the collections of moral and legal traditions traced to the Prophet, which supplement the Koran, somewhat like the Mishna (q. v.), which supplements the Laws of the Pentateuch. The Sunna not only comprises religious doctrines and practice, but also civil and criminal laws, and the usages of common life: the way to eat and to drink, and to dress, and the like. This tradition is first heard of during the civil wars among the adherents of the new faith, about half a century after the Flight. The single traditions, as we now possess them, rarely exceed six lines. The diction is carefully wrought, and the form is that of a dialogue. For the credibility and canonicity of a tradition, it was originally necessary that it should have been *heard* by one truthful witness; but this law was much relaxed in after-time. At the end of the 3d c. (H.), a countless number of individual collections (Mosnad), mostly of an apocryphal character, had been produced by different theologians, but the first who sifted them critically, and without regard to any special theological system, was Bochary (d. 256 H.). His collection contains 7275 single traditions, 4000 of which, however, occur twice in the work. Moslim, his pupil, supplemented Bochary with another collection, containing 12,000, again including 4000 repetitions. Besides these, there are four more 'canonical' collections; by Abû Dawûd (d. 275 H.), Tirmidzy (d. 279), Nasây (d. 303), and Mâga (d. 273). The Sunna, as we have it in these collections, contains, broadly speaking, more truth than it is generally supposed to contain, and, critically used, is, besides the Koran, the most authentic source of Islam. A selection from the different collections (both canonical and otherwise), called *Mishcat Al Masabih*, has been translated into English by Captain Matthews (Calcutta, 1809). Fragments from Bochary are found in a German translation, by Hammer, in the *Fundgruben des Orients*.

SU'NNITES, traditionists or believers in the Sunna (q. v.); the name of the 'orthodox' Muslims, as opposed to the Shiites (q. v.). They are subdivided into four principal sects, who, though at issue on different minor points, yet are acknowledged, by each other, to belong to the Faithful, and to be capable of salvation, and they each have a special oratory at Mecca. The first of these sects are the Hanefites, founded by Abu Hanifa, who died 150 years after the Hedjrah. They are emphatically called 'the followers of reason,' whilst the other three are guided exclusively by tradition. They allow reason to have a principal share in their decisions on legal and other points. To this sect belong chiefly the Turks and Tartars. The second sect are the Malekites, founded by Malek Ibn Ans, who died about 180 H. at Medina. As one of the chief proofs of his real piety and humility, it is recorded that when asked for his decision on 48 questions, he would only decide on 16, freely confessing his ignorance about the others. In Barbary and other parts of Africa, the greatest part of his adherents are found. Mohammed Al Shâfeï, born in Palestine, 150 H., but educated in Mecca, is the founder of the third sect, the Shâfæites. He was a great enemy of the scholastic divines, and seems altogether to have been of an original cast of mind. He never swore by God, and always took time to consider whether he should at all answer any given question or hold his peace. The most characteristic saying recorded of him is: 'Whosoever pretends to love both the work and the Creator at the same time, is a liar.' He is accounted of such importance, that according to his contemporaries, 'he was as the sun to the world, and as health to the body;' and all the relations of the traditions of Mohammed were said to have been asleep until he came and woke them. He appears to have been the first who reduced Muslim jurisprudence into a method, and thus made it, from a number of vague sayings, a science. His followers are now chiefly found in Arabia and Persia. Ahmed Ibn Hanbal founded the fourth sect, the Hanbalites. He was born 164 H., and was a most intimate friend of Shâfeï. His knowledge of the traditions (of which he could repeat no less than a million) was no less famed than was his piety. He taught that the Koran was not created, but everlastingly subsisted in the essence of God; a doctrine for which he was severely punished by the Calif Al-Motasem. On the day of his death, no less than 20,000 unbelievers (Jews, Christians, and Magians) are said to have embraced the Mohammedan faith. Once very numerous, the Hanbalites now are but very rarely met with out of Arabia. On the differences between the S. and Shiites, see SHIITES.

SUN-STROKE (otherwise called *Heat Apoplexy*, *Heat Asphyxia*, *Coup de Soleil*, *Erythismus tropicus*, and *Insolatio*, the name by which it is officially known in the returns of the Registrar-general) is a very fatal affection of the nervous system, which seldom occurs in Great Britain, except in extremely hot summers, but is very common in India and other tropical countries. Our knowledge of the nature of this remarkable disease is almost entirely based upon the accounts which have been given of it by Indian medical officers. It is from their reports that the most satisfactory history of this disease at present published—that, namely, of Dr Aitken in his *Science and Practice of Medicine*, 3d ed., 1864—is mainly drawn up. From the accounts given by these observers, it is clear that the symptoms of the disease are liable to be greatly

modified in different cases. Mr Russell, when in charge of the 68th Regiment in May 1834, shortly after its arrival at Madras, with the men in robust health, has given the following account of this disease. 'The funeral of a general officer being about to take place, the men were marched out *at an early hour in the afternoon, buttoned up in red coats and military stocks, at a season, too, when the hot land winds had just set in*, rendering the atmosphere dry and suffocating even under the shelter of a roof, and when the sun's rays were excessively powerful. After having proceeded two or three miles, several men fell down senseless. As many as eight or nine were brought into hospital that evening, and many more on the following day. Three men died--one on the spot, and two within a few hours. The symptoms observed (and they were alike in the three cases) were, first, excessive thirst, and a sense of faintness; then difficulty of breathing, stertor, coma, lividity of the face, and in one whom Mr Russell examined, contraction of the pupil. The remainder of the cases (in which the attack was slighter, and the power of reaction perhaps greater) rallied; and the attack in them ran on into either an ephemeral or a more continued form of fever.' Aitken, *op. cit.* One of the earliest symptoms, noticed by several observers, is the skin becoming rough and scaly, and the perspiration ceasing; the heat of the surface becomes at the same time much increased; the bowels become obstinately constipated. The actual attack, in the various cases described by the Indian surgeons and physicians, came on generally when the men were in their tents, sometimes during the day, but in several cases during the night. The patient had been generally lying down, often seemingly asleep, when the attention of his comrades would be directed to his hurried and heavy breathing, and on attempting to rouse him, he was found to be insensible. The mortality from sun-stroke is about 50 per cent. In the cases that terminate favourably, a gradual remission of the symptoms takes place; and when the skin becomes cool and moist, and sleep has been procured (phenomena which usually occur within 36 hours of the attack), the patient may be regarded as out of danger.

The predisposing causes of sun-stroke are (1), an unusually elevated degree of temperature, accompanied by great dryness of the air; (2) The electrical condition of the atmosphere that precedes a thunderstorm; (3) A contaminated atmosphere from overcrowding; (4) All debilitating causes, such as prolonged marches, previous disease, intemperate habits, &c. Death sometimes occurs so suddenly that there is little opportunity for treatment, but the general indications in these cases are—the cold douche, from a height of three or four feet, keeping the surface wet and exposed to a current of air, the exclusion of light as far as possible, and the free employment of stimulants. In less rapidly fatal cases, the outer clothing should be removed, and the douche applied, as before, over the head and along the spine. Relaxation of the pupil is the first favourable sign. If the pulse flags, the douche must be replaced by the mere application of cold to the head. The hair must be cut as short as possible, and the nape of the neck blistered as speedily as possible. If insensibility recurs after an interval of ten or twelve hours, a blister should be applied to the crown of the head. The extremities and chest should be stimulated with mustard poultices. Immediately after the employment of the douche, a strong purgative injection should be thrown up the lower bowel, by means of a long stomach-pump tube (as, for example, a mixture of an ounce and a half each of castor oil and oil of turpentine, and two drachms of tincture of asafœtida in about half a pint of barley-water). Under no circumstances, should there be any abstraction of blood. The preventive measures are of more importance than the treatment; but this is a subject into which we have not space to enter. The advice of the regimental surgeon is too often disregarded by the commanding officer; and the lines which are italicised in Mr Russell's account of the cases—quoted at the beginning of this article—would seem to contain a well-devised prescription for the induction rather than the prevention of sun-stroke.

SUONADA (inland sea), an inland sea of Japan, which separates the island of Kiusiu and Sikopf from the larger one of Nipon. It is about 250 miles in length from the strait of Simonoseki to Osaca; and Sir R. Alcock estimates its greatest breadth at 50 miles. It is studded with innumerable islets and a few rocks. The scenery is picturesque. The prince of Nagato and Soulio having, contrary to treaty stipulations, closed this sea to foreign vessels and fired upon them, the English, French, and Dutch fleet destroyed the forts that barred its entrance (5th and 6th September 1864), with the loss, to the allied squadron, of 12 men killed and 60 wounded.

SUPERANNUA'TION is a retiring allowance granted under an act of 1859, 22 Vict. cap. 26, to all persons not being weekly labourers employed permanently in the civil service of the country. Before the age of 60, retirement can only take place from broken health (or ostensibly so), or from abolition of office: after 60, any person may retire. If the retirement take place before completing ten years' service, a gratuity only is allowed. After ten years, the pension is $\frac{1}{60}$th of the salary at the time of retirement for every year of service, up to $\frac{40}{60}$ths, which is the maximum allowed, except under very special circumstances, when the Treasury may grant larger pensions, never, however, exceeding the salary vacated. Professional persons appointed later in life than the usual age, may have pensions computed with a number of years, not exceeding 20, added to their actual service. On the other hand, the Treasury may, for grave demerit, diminish a pension below the scale granted in the act. A person on a pension is liable to recall to a position as good as he vacated, up to the age of 60, if in suitable health. A civil servant is defined to be one holding appointment direct from the crown, or under certificate from the Civil Service Commissioners; and his salary must be paid out of the consolidated fund or out of moneys voted by parliament. Weekly labourers are ineligible; but artificers may serve for superannuation, provided they are not paid at the full current market rates of wages at their respective stations.

Superannuation is one of the great boons of the permanent civil service, in which the officials are, as a rule, paid salaries lower than they could earn elsewhere; but to render promotion tolerably certain, retirement at 60 should be, not, as now, voluntary, but compulsory. At present, an official may at his option serve as long as he is capable of attending office; and many actually do die in harness, years after they have become useless.

SUPERCA'RGO is an important officer in a merchant vessel, charged with the control of all her commercial transactions. The cargo is under his care, and he judges as to its disposal and replacement.

SUPEREROGA'TION, WORKS OF (Lat. *supererogata*, over and above things required), a class of works which, in the Roman Catholic system, are described as not absolutely required of each individual

as conditions to his eternal salvation. Roman Catholics found this definition on the distinction between what they believe to be commanded and what they hold to be only counselled, for an example of which they appeal to the words of our Lord to the young man in Matthew xix. 21, which distinguish one class of works which are necessary in order to 'enter into life,' and a further class which must only be done if we 'would be perfect.' Roman Catholics do not profess to recognise in works of supererogation any distinctive essential quality by which they differ, whether in their physical or their moral entity, from other works, and in virtue of which, by their own nature, the individual may found upon them a personal claim to reward. For works of supererogation, as for all supernaturally good works, they hold that the assistance of God's grace is indispensably necessary; and they do not ascribe to them any merit, except that which arises from God's own free and gratuitous promise. In one word, the only distinctive characteristic of a work of supererogation lies in its not being supposed to be prescribed or commanded as absolutely necessary for the salvation of the individual, and its being done for the sake of greater perfection; and the doctrine which teaches the possibility of such works is, according to Catholics, a necessary consequence of the unequal fervour and unequal degrees of holiness which exist even in the class of the virtuous servants of God. A further consequence of this doctrine is that God may accept the superabundant works of one in atonement for the defective service of another; and hence, in the Catholic theory of Indulgences (q. v.), along with what they regard as the infinite and inexhaustible treasure of the merits of our Lord, they also regard, although in a degree infinitely inferior, the superabundant merits of the saints as forming part of that 'treasure of the church' which is applied in the form of indulgences.

SUPERFŒTA'TION, or the circumstance of two distinct conceptions occurring in the same woman at an interval of greater or less duration, so that two fœtuses of different ages—the offspring possibly of different parents—may co-exist in the uterus, is a subject of great interest both in a scientific and in a medico-legal point of view. A couple of centuries ago, there was a universal belief in not only the possibility but the comparative frequency of this occurrence. Fifty years ago, it was as universally disbelieved; and now again (owing to the investigations of various inquirers, amongst whom Dr Bonnar of Cupar deserves special mention), we are returning to the belief of our ancestors. The cases described as instances of superfœtation may be arranged in three classes; but as will be presently seen, it is only to the cases of the third class that the term superfœtation is truly applicable. The *first class* includes the numerous undisputed cases in which two mature children, bearing evidence, from their different colours, that they are the offspring of different parents, are born at the same time. In the slave states of America, it was by no means uncommon for a black woman to bear at the same time a black and a mulatto child—the former being the offspring of her black husband, and the latter of her white lover; and the converse has occasionally occurred—a white woman at the same time bearing a white and a mulatto child. There is no difficulty in accounting for these cases, which are examples of contemporaneous conception rather than true superfœtation. The *second class* includes those cases in which a twin has been aborted, leaving its fellow undisturbed in the uterus, to be matured and born in due time, or in which twins have been produced at the same time, one of which was fully formed, while the other was small and apparently premature, from being 'blighted' or arrested in its development at an early period. Cases of these kinds are by no means rare; but there is no reason for believing that the infants were conceived at different periods. The *third class* includes the cases in which a *mature* child has been born, and an *immature* fœtus, the product of a different conception, has either been left in the womb until its period of maturation, or, if expelled along with the other, has presented no mark of wasting or of arrested development. 'In a case of genuine superfœtation,' says Dr Bonnar, 'a woman must bear two (or more) *mature* children, with an interval of weeks or months between the birth of each; or, if she part with the whole contents of the uterus at the first delivery, the difference of the ages of the fœtuses, or the mature child and the fœtus, as the case may be, must be unmistakable, and there must be the absence of all marks of blight of the latter, so as to leave no doubt that, had it remained in utero, it would have gone on to perfect maturity.' Amongst the cases of superfœtation that have been specially discussed by writers on Midwifery and Medical Jurisprudence, are the following: (1) Velpeau quotes from the *Recueil de la Société de Médecine* the case of a woman named 'Arles,' who, in 1796, gave birth to a child at the full time, and five months afterwards to another, which was also thought to be at the full time; (2) Dr Maton, an eminent London physician, communicated to the College of Physicians the case of Mrs T——, an Italian lady, who was delivered of an apparently healthy and mature male child on the 12th of November 1807, but which lived only nine days. On the 2d of February 1808, or 82 days after the birth of the first, she was delivered of a second child, which likewise had every sign of being completely formed and mature. The following case, which, as Dr Bonnar (in his *Critical Inquiry regarding Superfœtation*, Edin. 1865) observes, 'has been the principal battle-field of the advocates of superfœtation and their opponents,' and has given rise to more discussion than any other, is recorded by Dr Desgrange of Lyon. Madame Villard had a miscarriage at seven months on the 20th of May 1779. In about a month thereafter, she conceived again, and on the 20th of January 1780, she brought forth a living child. No milk appeared in her breasts, the abdomen did not seem to diminish in size, and other symptoms which normally follow delivery were absent. The two surgeons who were in attendance being naturally puzzled, called in Dr Desgrange, who declared, in opposition to their views, that there was still a child in the womb; and his opinion was confirmed by her being delivered of a living child on the 6th of July 1780, 167 days after the first birth. Dr Bonnar has collected from *The Peerage* a number of cases of probable superfœtation occurring in married life. Excluding a very few exceptional cases, he adopts Dr William Hunter's view, that 210 days, or seven calendar months, is the minimum period of uterine life at which a child should be born in order to be reared, and he assumes that no prolific intercourse can take place until at least fourteen days after the first delivery; and with these axioms, he quotes the following cases: (1) In the Hamilton (Lord Mountflorence) family, a daughter, who was born 182 days after the birth of a son who reached maturity, lived to be married, whose supposed uterine life was not more than 168 days. (2) In the Aukland family, the Honourable William Frederick Elliot, who was born 173 days after the birth of a sister (who lived 60 years), survived 28 years, although his assumed

uterine life was only 159 days. (3) Lord Cecil J. Gordon, brother to the Marquis of Huntly, has a son, Cecil-Crosbie, who was born in January 1850 (only 127 days after the birth of a previous child). This son is now alive, and his assumed period of gestation was only 113 days. 'We cannot conceive,' says Dr Bonnar, 'how these three cases can possibly be explained except by the doctrine of superfœtation;' and Dr Taylor (*Principles and Practice of Medical Jurisprudence*, p. 849) fully adopts his view. Dr Duncan believes, from anatomical investigations, that up to the third month of gestation, a second conception may follow the first; and he is of opinion that this will satisfactorily account for all the cases of superfœtation on record.

SUPE'RIOR, in Scotch Law, means one who, or whose predecessor, has made a grant of heritable property to a vassal, on condition of the latter paying an annual duty or sum of money, generally called a feu-duty. The superior is said to have the superiority, or *dominium directum*, and the vassal has the feu, or *dominium utile*. In popular language, the superior is a kind of landlord. See FEU.—In England, the word is not used, though in copyhold estates the term 'lord' corresponds to it.

SUPERIOR, LAKE, the largest body of fresh water in the world, is the highest and most western of the great lakes lying between Canada and the United States. It is situated not far from the centre of the North American continent. Its general form is nearly semi-lunar, the outer curve being towards the north. Greatest length from east to west, 355 miles; greatest breadth, 160 miles; area, about 32,000 sq. m.—fully that of Ireland. The surface of the lake is about 630 feet above the level of the sea, and its mean depth 1000 feet, so that its bottom is 400 feet below the level of the sea. Its surface has an elevation of about 22 feet above that of Lake Huron and Lake Michigan. The greater portion of this rise is at the Sault Ste. Marie, a strong rapid about a mile in length, at the commencement of the river St Mary, which transmits the waters of Lake S. to Lake Huron.

Lake S., being situated very near the watershed between Hudson's Bay and the Mississippi, receives no rivers of importance, although hundreds of small rivers pour themselves into it. The largest are the St Louis River, which falls into its western extremity at Fond du Lac, and is about 110 miles long; and the Neepigon River, on the north side, which, with the lake of the same name, has a length of about 200 miles. One of the branches of the Mississippi in Minnesota approaches to within 20 miles of the western extremity of Lake S.; and a small lake near the head of the Albany River, of which the waters flow to Hudson's Bay, is only four miles from a bay opposite the State Islands on the northern shore, forming a route with little portage, which has long been used by the Hudson's Bay Company for the conveyance of goods from Lake S. to the northern country.

The promontory, Kee-wee-naw, near the middle of the south side, projects far into the lake. The islands are not numerous, the largest being Isle Royale, 44 miles long.

The country around Lake S. is generally bold and hilly, with the exception of the peninsula lying between it and Lake Michigan; but few of the hills rise more than 1000 feet above the level of the lake, and most of them are far below this height. On the southern shore, 100 miles west of the Saulte Ste. Marie, are the Pictured Rocks, cliffs of gray and red sandstone from 100 to 200 feet high, in many places presenting fantastic forms, and marked by numerous perpendicular stripes of red and yellow, from ferruginous waters trickling down the face of the rock.

The boundary between the United States and Canada, starting from the outlet of the lake at the Saulte Ste. Marie, sweeps towards the north, so as to include in the United States even the Isle Royale, which is only 13 miles from the British coast, and strikes inland from the mouth of Pigeon or Arrow River, on the north-west shore.

The only obstacle to navigation between Lake Huron and Lake S. is the Saulte Ste. Marie, which is overcome by a canal of about a mile in length, with two locks, on the American side. This is, perhaps, the finest canal in the world. The sides and bottom are lined with stone throughout its whole length, the locks are admirably contrived and the largest ships can pass through it with ease The trade is increasing so rapidly, that a canal on the British side will also be required at no distant day.

The water of Lake S. is remarkable for its coldness, purity, and transparency, although the affluents on both sides are either turbulent, or deeply coloured by vegetable matter from swamps and forests.

A rise or fall in the level of the water, amounting to several inches in a few hours, is frequently to be observed along the shore, and has been supposed to be due to a regular tide, but is probably caused by the wind. Fresh water being more easily moved by the wind than salt water, great waves arise in Lake S. with wonderful rapidity; and even in summer, large steamers are compelled to take shelter in some bay, or under the lee of an island. Owing to the low temperature of the water, compared with that of the air, in summer, fogs are prevalent, resting on the water at night, and vanishing an hour or two after sunrise.

Lake S. never freezes over, but the bays are sealed up in winter, and a rim of ice extends to some distance all around the shore.

The rocks around the lake are very ancient, belonging principally to the Laurentian and Huronian systems of the Azoic series, overlaid in some places, especially on the south side, with patches of the Lower Silurian. The prevalent Laurentian rock is orthoclase gneiss. Among the Huronian rocks are greenstones, slates, conglomerates, quartzites, and limestones. The Lower Silurian rocks are soft sandstones. There is everywhere much evidence of glacial action.

The Huronian rocks are well stored with useful minerals. The copper and iron mines of the south side are celebrated for their extent and richness, and silver deposits of immense value have been very recently discovered on Silver Island, on the British side, although as yet they are comparatively undeveloped. The richest copper-mines are situated near Kee-wee-naw Point. The metal occurs principally native, and sometimes in single masses of great size. One was met with in 1853, which measured about 40 feet in length, and was calculated to weigh about 400 tons. Native silver is found associated with the native copper, and sometimes intimately mixed with it. Gold has been found in small specks at Namainse on the British side. Lead ore occurs in some places. The beds of hæmatite, or red iron ore, at Marquette, on the south side, are of wonderful extent. They are situated about 12 miles inland. The ore is conveyed by a railway to the harbour thence by vessels to Cleveland, on Lake Erie, and thence by rail to Pittsburgh, where it is smelted The quantity exported from Marquette in 1864 amounted to 300,000 tons.

The fisheries of Lake S. deserve notice. The delicious white-fish and the gray trout abound, as

well as other kinds of fish. The Canadian legislature passed a law in 1865 to put a stop to the wholesale destruction of them on the spawning grounds.

The shores of Lake S. are frequented by bands of the Ojibbeway tribe of aborigines. They are of very pure blood, retain in a great measure their primitive habits, and many of them are still pagans. They seem incapable of adapting themselves to the settled life of the white man.

The white population of the British shore of Lake S. consists as yet only of the fishermen and explorers who visit the region during summer, and the miners at the rich deposits of silver ore recently opened on Silver Island, near Thunder Bay. But on the American shore a number of thriving towns have sprung up, some of them containing several thousand inhabitants. Marquette is connected by a railway with Ontonagon, also with Green Bay, on Lake Michigan, and thus with Milwaukie and Chicago; and Duluth, at the western extremity, is the eastern terminus of the N. Pacific R.R. See Disturnell's *The Inland Seas*, 1871.

SUPERPHO'SPHATES. See Phosphorus.

SUPERTO'NIC, in Music, the note which, in the diatonic scale, is next above the tonic or keynote, and forms with it the interval of the second, as D in the key of C major.

SUPPLY', Commissioners of, persons appointed by the acts imposing the land-tax in Scotland, to assess, and formerly also to collect, that tax. Their principal duty now is to assess the land-tax, and apportion the valuation according to the provisions of the Valuation of Lands Act, 17 and 18 Vict. c. 91. They are entitled to name a convener, who acts as preses of the meeting, and a clerk with a reasonable salary. The qualification, as recently modified by 17 and 18 Vict. c. 91, consists in the being named as an *ex officio* Commissioner of Supply in any act of supply; or the being proprietor, or husband of a proprietor, of lands of the yearly value of £100; or the eldest son of a proprietor of lands of the yearly value of £400: and a factor of a proprietor of lands of the yearly value of £800 is empowered to act as Commissioner of Supply in his absence.

By act 17 and 18 Vict. c. 91, the Commissioners of Supply of every county, and magistrates of every burgh, must cause a valuation roll to be made up yearly, shewing the rents of all lands or heritages in the county or burgh, and the names of the proprietors and tenants; and for this purpose, they are empowered to appoint an assessor or assessors. A yearly court is to be held by the commissioners and magistrates, for hearing appeals against the determinations of the assessors, in which three Commissioners of Supply and two magistrates are to form a quorum, the preses having a casting-vote in case of equality. See Valuation, Land-tax.

SUPPLY, Committee of. The sums granted in parliament to defray the public expenditure for the current year are called *Supplies*. All bills authorising the expenditure of public money must originate in the House of Commons, and be based on resolutions moved in a Committee of Supply, which is always a committee of the whole House. The House having resolved that a supply be granted to her Majesty, resolves itself into a Committee of Supply. The various estimates are submitted to the committee, which has to consider what specific grants are to be voted; and the resolutions of the committee are reported to the House, and adopted or rejected. It belongs to another committee of the House, the 'Committee of Ways and Means,' to consider how the sums shall be raised which are voted by the Committee of Supply. See Ways and Means, Parliament.

SUPPO'RTERS, in Heraldry, figures placed on each side of an armorial shield, as it were to support it. They seem to have been, in their origin, a purely decorative invention of medieval seal-engravers, often, however, bearing allusion to the arms or descent of the bearer; but in the course of time, their use came to be regulated by authority, and they were considered indicative that the bearer was the head of a family of eminence or distinction. The most usual supporters are animals, real or fabulous; but men in armour are also frequent, and Savages (q. v.), or naked men, often represented with clubs, and wreathed about the head and middle. There are occasional but rare instances of inanimate supporters. On early seals, a single supporter is not unfrequent, and instances are particularly common of the escutcheon being placed on the breast of an eagle displayed. The common rule, however, has been to have a supporter on each side of the shield. The dexter supporter is very often repeated on the sinister side, but the two supporters are in many cases different: when the bearer represents two different families, it is not unusual for a supporter to be adopted from the achievement of each.

In England, the privilege of bearing supporters as now defined belongs to the sovereign and princes of the blood, peers and peeresses, and the heads of a very few families not of the peerage, whose right is based on an ancient patent, or very early usage. No right is recognised by the College of Arms as

Arms of Duke of Argyll.

belonging to the sons of peers bearing courtesy titles. Knights of the Garter and Knights Grand Cross of the Bath are dignified with supporters, which, however, are not hereditary. Supporters have also been assigned to the principal mercantile companies of London. In Scotland, the use of supporters is somewhat less restricted. The distinction was much less wide than in England between the greater and lesser barons (see Minor Barons), and the right to supporters was considered to belong to the latter, so long as the baronial statute conferred a right to sit in parliament. The act of 1587, which finally excluded the lesser barons from the Scottish parliament, and established a systematic parliamentary representation, was not held to interfere with this armorial privilege, and it is yet the practice of the Lord Lyon to grant or confirm supporters to the representatives of all minor barons who had full baronial rights prior to that date. A limited number of heads of important families, including the chiefs of the larger Highland clans, apart from considerations of barony, participate in the right to supporters. Lyon is also considered to have it in his power to confer them *ex gratiâ*, a prerogative which is but sparingly exercised, one of the instances of such departure from strict rule having been in favour of Sir Walter Scott. Nova Scotia baronets as such have no right to supporters, though many

of them bear them in respect of the baronial qualification.

The lion and unicorn, familiar in the royal arms of the United Kingdom, were adopted, the former from the achievement of England, the latter from that of Scotland prior to the union of the crowns.

In the more modern heraldry, supporters generally stand either on an escrol, containing the motto, or, more properly, on a carved panel of no definite form, which in Scotland is known by the name of a *compartment*.

SUPPURA'TION is a morbid process which gives rise to the formation of Pus (q. v.), which, as is well known, is one of the commonest products of inflammation. There are two doctrines as to the origin of pus. The opinion universally adopted till very recently was, that it was formed from an excessive exudation of the fluid portions of the blood through the walls of the capillaries; in which exudation, under certain conditions, pus-cells were developed. This view is now rejected for the doctrine of Virchow, the eminent professor of pathology at Berlin, who maintains that pus-cells are generated from the corpuscles of areolar tissue, which he supposes to permeate nearly every portion of the body. Pus, according to Virchow, is a young tissue in which, amidst the rapid development of cells, all solid intercellular substance is gradually dissolved. A single cell of areolar or connective tissue may, in an extremely short space of time, produce some dozen of pus-cells; but the result is of no service to the body, suppuration being, to use his own words, 'a pure process of luxuriation, by means of which superfluous parts are produced, which do not acquire that degree of consolidation or permanent connection with one another, and with the neighbouring parts, which is necessary for the existence of the body.' There are two different modes of pus-formation, according as the pus proceeds from Epithelium (q. v.) or from connective tissue (see CELLULAR TISSUE). When pus is formed from epithelium, it is produced without any considerable loss of substance, and without ulceration; but when it is formed from connective tissue, ulceration must always exist. The mucous membranes vary in their power of forming pus. A mucous membrane, according to Virchow, is the more qualified to produce pus without ulceration the more completely its epithelium is stratified, those with a single layer of epithelium being less adapted for the production of pus. Thus the intestinal mucous membrane scarcely ever produces pus without ulceration; while other mucous membranes, containing several strata of cells, are capable of secreting enormous quantities of this fluid without the slightest ulceration (as, for example, the urethral mucous membrane in gonorrhœa).

The above cases of suppuration occur on free or exposed surfaces, and are unaccompanied with loss of tissue. Deep-seated pus-formation takes place only in connective tissue. The first stage of formation consists in an enlargement of the normal cells, and a division and excessive and rapid multiplication of their nuclei. This is soon followed by division of the cells themselves, and their conversion into true pus-cells. If this process takes place beneath a surface which does not participate in the morbid change, or which is capable of resisting it for a time, an *abscess* is formed; whereas, when pus-cells are poured forth from an exposed surface, we have an *ulcer*.

Although suppuration is a morbid process, it often accompanies processes of a beneficial tendency (such as granulation), and frequently takes the place of other far more morbid processes. It further affords a mechanical means of removing foreign bodies, such as thorn, splinters of glass, &c., from soft parts into which they may have been driven; and it is possible (as some pathologists believe) that the formation of abscesses may sometimes serve to eliminate morbid matters from the system.

SUPRALAPSA'RIAN (Lat. *supra*, before, *lapsus*, the Fall), the name given to the school of divines which maintains that God's absolute decree of election and reprobation is antecedent to His foresight of the fall of Adam, and irrespective of it. See SUBLAPSARIAN.

SUPRA-RE'NAL CAPSULES AND THEIR DISEASES. The supra-renal capsules are two small, flattened, glandular bodies of a yellowish colour, situated, as their name implies, immediately in front of the upper end of each kidney. In weight they vary from one to two drachms. They belong to the class of ductless glands, and on making a perpendicular section, each gland is seen (like the kidney) to consist of cortical and medullary substance. The blood-vessels and nerves of the glands are exceedingly numerous. Of late years, much attention has been drawn to the diseases of these organs from the observation of the late Dr Addison (of Guy's Hospital), that such cases are frequently associated with the deposition of pigment in the skin, causing it to assume a deep bronze colour. The following definition of *Addison's Disease*, or *Supra-renal Melasma*, or *Bronzed Skin Disease*, embracing all the most important points in its natural history, is given by Dr Aitken: 'A morbid state, which establishes itself with extreme insidiousness, whose characteristic features are anæmia, general languor and debility, and extreme prostration, expressed by loss of muscular power, weakness of pulse, remarkable feebleness of the heart's action, breathlessness upon slight exertion, dimness of sight, functional weakness and irritability of the stomach, and a peculiar uniform discoloration of the skin, which becomes of a brownish olive-green hue, like that of a mulatto, occurring in connection with a certain diseased condition of the supra-renal capsules. The progress of the disease is very slow, extending on an average over one year and a half, but may be prolonged over four or five. The tendency to death is by asthenia, the heart becoming utterly powerless, as if its natural stimulus—the blood—had ceased to act.'—*The Science and Practice of Medicine* (3d. ed. vol. ii. p. 72). The numerous cases recorded by different physicians of all countries since Dr Addison's original observations were made, shew that the connection between *bronzing* of the skin and various morbid states of the supra-renal capsules is a fact beyond all dispute; but the exact relationship and pathological significance of the morbid states thus connected are still open questions. The special morbid changes in the capsules necessary for the production of the symptoms which constitute the disease, are first the deposition of a translucent, softish substance; the degeneration of this to a yellowish-white opaque matter; and afterwards a softening into an abscess, or drying up into a chalky mass. In the way of treatment, nothing can be done but to attempt to improve the general health by nourishing food, tonics, &c. The literature of this very singular disorder is mainly to be found in various memoirs in the *Guy's Hospital Reports*.

SUPRE'MACY, ROYAL. The term supremacy is, in politics, chiefly used with regard to authority in matters ecclesiastical. From the time of Pope Gelasius (494 A.D.) to the Reformation, the pope exercised a very extensive authority, judicial, legislative, and executive, over all the churches of Western Europe, somewhat undefined in its limits,

varying in different countries and at different periods; which continues to be more or less recognised in all countries whose inhabitants are in communion with the Church of Rome. At the English Reformation, the papal supremacy was abolished, and act 26 Henry VIII. c. 1, declared the king and his successors to be the 'only supreme head on earth of the Church of England.' A curious document was at the same time drawn up by the government, in which, to avoid misconception, it was explained that the recognition of this headship of the church implies only that the king should have such power as of right appertaineth to a king by the law of God, and that he should not take any spiritual power from spiritual ministers, or pretend to 'take any power from the successors of the apostles that was given them by God.' In 1535, the same year in which this act was passed, John Fisher, bishop of Rochester, Sir Thomas More, and others, were beheaded for denying the king's supremacy; and in 1578, John Nelson, a priest, and Sherwood, a young layman, suffered the punishment of death for the same offence. The assumption by Henry VIII. of the title of 'Head of the Church,' notwithstanding the explanation alluded to, was much commented on; and on the accession of Elizabeth, it was thought prudent, while again claiming the supremacy in all causes, as well ecclesiastical as civil, to keep that designation in the background. By successive statutes, the oath of supremacy has been appointed to be taken by the holders of public offices along with the oath of allegiance and of abjuration, and these three oaths have been consolidated into one by 21 and 22 Vict. c. 48. In 1866, a bill was before parliament for imposing a new short form of oath—in place of the oaths hitherto in use to be taken—on members of both Houses of Parliament, in which the royal supremacy in matters ecclesiastical is not in express words specified. See ABJURATION and OATH.

SURABAY'A, a leading seaport of Java, and capital of a residency, is situated on the Kali Mâs mouth of the river Kedirie, near the Strait of Madura, the citadel being in 7° 4′ 30″ S. lat., and 112° 40′ 40″ E. long. Pop. of city and suburbs is about 100,000. The European town is on the west bank, five bridges connecting it with the Chinese and Javan quarters on the east. There are 2 Protestant clergymen, a Roman Catholic priest and assistant, 4 government and 6 adventure schools for Christian children. There are regular steamboat services to Samarang, Batavia, and other places. The steam and sailing vessels belonging to S., in 1864, were 62, and an average of 750 sea-going ships arrive and depart annually. The residency of S. comprises an extensive tract of fertile land in the north-east of Java, and the island of Madura. In 1861, the population numbered 1,218,827, including 4217 Europeans and 7436 Chinese. Rice, coffee, sugar, indigo, cotton, tobacco, and coco-nuts are extensively cultivated.

SURAKA'RTA, a residency of Java, south-east from Samarang, has an area of 2366 sq. m., is fertile and well cultivated, producing rice, maize, sugar, coffee, tea, indigo, tobacco, pepper, cacao, vanilla, and abundance of tropical fruits. In 1861, the population, including 1595 Europeans, amounted to 717,135. The people are proud, and less obedient than in the other residencies, but abjectly submissive to the native emperor, though, in many things connected with his government, he must consult the European resident.

Surakarta, the capital of the empire, and seat of the residency, lies on the left bank of the Solo, in 7° 31′ 30″ S. lat., and 110° 46′ 7″ E. long., covers a large space, and has a population of over 100,000. Many princes and nobles have their palaces in S.; that of the emperor is of great extent and splendour, 10,000 persons, belonging to, or in the service of the royal family, living within the wall. North-east from the royal parks lies the European town, in front of which, surrounded by the parade ground, and commanding the palace, is a square fort, with broad canal and drawbridges at the four curtains, and mounted with 30 pieces of heavy artillery. There is a normal school for training Javanese teachers; a government school, with 80 pupils; and an adventure girls' school, with 40 pupils. A railway is being formed from Samarang to S., by which the produce will be easily conveyed to the port of shipment, and an impulse given to trade and agriculture.

SURA'T (Sans. *Surashtra*, good country), a large but declining city of British India, 150 miles north of the city of Bombay, on the south shore of the Taptí, and 8 miles from its mouth in the Gulf of Cambay. It is 6 miles in circumference, and it is surrounded on the landward side by a brick wall. The river at S. is said to be fordable, although at high tide it can float vessels of 50 tons burden. The English and Portuguese factories, the former now used partly as a lunatic asylum and partly as hospital, are both imposing edifices of great strength and solidity. S. is said to have contained—but this is probably an exaggeration—800,000 inhabitants at the close of the 18th c., about which time its markets were crowded with the costliest wares, brought by merchants from the remotest countries. Its trade and manufactures are now almost extinct, though it still exports cotton and grain to Bombay, and is a place of considerable military strength, and the residence of a British military commandant and other dignitaries. The population is estimated at about 75,000.

S. was long thought to be one of the most ancient cities of Hindustan, but this opinion is now abandoned, and it is believed to have been a mere fishing-village as late as the 13th century. It first rose into importance as the spot whence the Mohammedans of Hindustan embarked on their religious voyage to Mecca. S. was sacked in 1512 by the Portuguese soon after their arrival in India. In 1612, an English force arrived here in two vessels, under the command of Captain Best, who defeated the Portuguese, and obtained a *firman* from the Mogul emperor, authorising the residence of a British minister. The Dutch trade with S. commenced in 1616, when a Dutch factory was established. A French factory was founded in 1668. In the course of time, the English influence began to predominate. In 1759, the castle and fleet were made over to them; and from the year 1800 the government of the settlement has been entirely vested in their hands.

SU'RBASE. See PEDESTAL.

SURD. See IRRATIONAL NUMBERS.

SU'RETY. See GUARANTY.

SURFACE GRUB, the caterpillar of the *Great Yellow Underwing Moth* (*Triphæna pronuba*), a pretty large moth, with the upper wings deep brown or pale tawny, the under wings bright orange with a black border. This moth abounds in hay-fields in Britain at the season of haymaking. The caterpillar, when full grown, is nearly an inch and a half long, pale green with a tinge of brown, dotted with black, three pale lines down the back

and seven black spots on the inside of each of the two outer ones. It often does great mischief to

a Surface Grub; b, Chrysalis; c, the Moth (*Triphæna pronuba*).

the roots of cabbages and turnips, and also devours the roots of grass.

SURF DUCK, or SURF SCOTER (*Oidemia perspicillata*), a species of Scoter (q. v.) extremely plentiful on the coasts of Labrador, Hudson's Bay, and other very northern parts of America, from which great numbers migrate southwards in winter. It is a rare visitant of the coasts of Britain and

Surf Duck (*Oidemia perspicillata*).

other parts of Europe. In size, it is about equal to the Mallard. The plumage is black, except two patches of white on the head and back of the neck. It is never seen on lakes or rivers, but only on the sea-coast. It dives so quickly, that it is very difficult to shoot except when on the wing. Its flesh is rank, and has a fishy taste.

SU'RGEON, Military and Naval, is the second grade attained by a medical officer. Every regiment of cavalry and battalion of infantry, and every ship of war above the size of a gun-vessel, has a surgeon. In the army, the pay of this officer varies with service from £273, 15*s.* to £328, 10*s.* a year, and he ranks as a major. After 20 years' full-pay service (as assistant-surgeon and surgeon) he becomes a surgeon-major, ranking as lieutenant-colonel, and receiving at first £401, 10*s.* a year, and five years later, £456, 5*s.* Naval surgeons have the same rates of pay, the rank of staff-surgeon taking the place of that of surgeon-major. The surgeons rank as naval lieutenants, and the staff-surgeons as commanders.

SURGEONS, College of. The present 'Royal College of Surgeons of England' dates its origin from the year 1460—1461, when Edward IV. 'did, at the supplication of the freemen of the mystery of barbers of the city of London using the mystery or faculty of Surgery, grant to them that the said mystery, and all the men of the same mystery of the said city, should be one body and perpetual community.' In 1500, four Masters in Surgery were appointed, under the title of 'Magistri sive Gubernatores mistere Barbitonsorum et Sirurgicorum' (*sic*), and six years after this date the Barber-surgeons of Edinburgh were incorporated by a charter from James IV. Although the original charter granted to the Company of Barbers of London was confirmed by several succeeding kings, many persons practised surgery independently, and apparently in defiance of the Company; and in order to check unqualified persons, it was enacted in the 3d year of Henry VIII. (1511) 'that no person within the city of London, or within seven miles of the same, shall take upon him to exercise or occupy as a physician or surgeon except he be first examined, approved, and admitted by the bishop of London, or by the dean of St Paul's, calling to him four doctors of physic, and for surgery other expert persons in that faculty.' Hence arose a company called the Surgeons of London. In the 32d year of Henry VIII. (1540), the Company of Barbers of London and the Company of Surgeons of London were united 'by the name of the Masters or Governors of the Mystery and Commonalty of the Barbers and Surgeons of London.' It was not till the 18th year of George II. (1745) that the surgeons of London were by act of parliament separated from the barbers of London, and made a distinct corporation under the name of 'The Master, Governors, and Commonalty of the Art and Science of Surgery of London.' In the 40th year of George III. (1800), this company was dissolved, and replaced with their former and additional privileges by 'The Royal College of Surgeons of London.' A new charter was granted to the college in the 7th year of Victoria (1843), in which it is declared 'that it is expedient to create a new class of members, to be called Fellows,' and 'that from henceforth the corporate name or style of the said college shall be The Royal College of Surgeons of England.' Power was given to the council to elect not less than 250, nor more than 300, members of the college to be Fellows. These 'first Fellows' were mainly elected from the London and provincial hospital surgeons. Other Fellows might subsequently be elected from the members, 'after having complied with such rules and regulations as shall be considered expedient, and after having passed a special examination.' Those who are admitted to the fellowship by examination are distinguished in the college list by the letters *Ex.* being prefixed to their name. By an addition to the charter, obtained in 1852, power was given to the council, subject to certain regulations, to appoint members of 15 years' standing to the fellowship without examination. The college was likewise empowered to test the fitness of persons to practise midwifery and to grant certificates of such fitness; and in 1859 it was similarly authorised to test the fitness of persons to practise as dentists, and to grant certificates of such fitness.

The government of the college is vested in a Council of twenty-four persons, including one president and two vice-presidents; and none but Fellows of 14 years' standing are eligible as members of council. Three members of council go out annually by rotation, and the vacancies are filled up on the first Thursday of July. There is a Court of Examiners consisting of ten members, including a president and two vice-presidents, and as the examiners, who receive large emoluments (the fees to the Court of Examiners for the professional examination of

members for the year ending June 24, 1865, were £2059, 14*s.*), are elected by the council, whose remuneration is slight, a position in the council is eagerly sought for as a stepping-stone to an examinership. Besides the Court of Examiners, there are special boards of examiners in Midwifery, in Dental Surgery, and in Classics, Mathematics, and French for the preliminary fellowship examination. There are two professorships in the gift of the college—viz., that of Human Anatomy and Surgery, now held by Mr Hancock; and the Hunterian Professorship of Comparative Anatomy and Physiology, held for 21 years by Professor Owen, and at present occupied by Mr Huxley. A Hunterian Orator is appointed every second year. The college sends a representative to the General Council of Education and Registration. A candidate for the membership of the college is required to pass a preliminary examination in the usual branches of a liberal education. The fee for the anatomical examination is £5, 5*s.*, and that for the surgical, or pass-examination, is £16, 15*s.*, making a total of £22. The fellowship fee is an additional 10 guineas. For details regarding the course of professional study required both for the membership and the fellowship, the reader is referred to the *Calendar of the Royal College of Surgeons of England*, 1865, which also contains complete lists of the Fellows, Members, Licentiates in Midwifery, and Licentiates in Dental Surgery.

While the movements of the College of Physicians are accurately known, there is considerable doubt as to the various localities occupied in early times by the barbers and surgeons. The Barbers' Hall is, or was, in Monkwell Street, City, but is doomed to fall before civic improvements. Stow, in his *Survey of London*, says there was a 'Chirurgeons' Hall near unto Aldersgate.' In 1596, it is recorded that Dr Paddy was chosen first 'Reader of the Anathomy (*sic*) Lecture at Barber-surgeons' Hall;' but, unfortunately, it is not stated where the hall was then situated. Subsequently, there was a 'Chirurgeons' Hall' in the Old Bailey, from whence the College removed at the commencement of the present century to the site which it now occupies in Lincoln's Inn Fields.

The Museum of the College of Surgeons is incomparably the finest museum of its kind in the United Kingdom. The Hunterian Collection (see HUNTER, JOHN), which forms its basis, was purchased by a parliamentary vote of £15,000, and presented to the college in 1799; and £12,500 more being subsequently voted for a public building, to which upwards of £21,000 were added from the College fund, the edifice in Lincoln's Inn Fields (the germ of the present pile of buildings) was completed, and the Museum was ready for inspection in 1813. Since that time, the building has been twice enlarged. The Hunterian Collection was estimated to consist of 13,682 specimens, of which 215 were microscopic preparations. The total number of specimens in 1865 was 40,701; the additions to the physiological and pathological departments amounting to 15,019, while no less than 12,000 microscopical preparations have been added. The formation of the Library only commenced with the present century; it contains about 35,000 volumes. Both the Museum and Library are readily accessible to visitors. The writer of this article cannot conclude without expressing his obligations to Mr Stone, clerk to the Royal College of Surgeons, for much valuable information.

SU'RGERY. There can be no rational doubt that surgery (Gr. *cheir*, the hand; *ergon*, work, signifying the manual interference, by means of instruments or otherwise, in cases of bodily injury, as distinguished from the practice of medicine, which denotes the treatment of internal diseases by means of drugs) is as old as man himself. Passing over the very little that is known regarding the state of surgery amongst the early Egyptians and the Jews, and the skill ascribed to Chiron and other mythical personages among the early Greeks, we may regard the true history of surgery as commencing with Hippocrates, who flourished in the 5th c. B. C. He was acquainted with the ordinary means of counter-irritation, as issues, a kind of moxa, and the actual cautery. He seems to have performed the capital operations with boldness and success; he reduced dislocations and set fractures, but clumsily and cruelly; extracted the fœtus with forceps when necessary, and both used and abused the trepan. He did not perform lithotomy, the practice of which seems at that time to have been well known, but to have been confined to a few, who made it their exclusive study. From the time of Hippocrates, we may pass over a couple of centuries, when, on the death of Alexander the Great, Alexandria became the great school of anatomy, surgery, and medicine. Herophilus and Erasistratus (300 B. C.) were as distinguished for their surgical skill as for their anatomical knowledge. One member of this school, Ammianus, invented an instrument by which he broke down stones in the bladder, thus anticipating by about 2000 years Civiale's discovery of lithotrity. When the great Alexandrian Library was destroyed by fire, Rome became the head-quarters of science in all its departments. The early Romans of all ranks held surgeons and physicians in abhorrence, and trusted for cures, even in cases of dislocation and fracture, to spells and incantations. The first regular surgeon who settled in Rome was Archagathus (220 B. C.), a student of the Alexandrian School. At first, his skill procured for him a high reputation, but the old prejudices soon revived, and he was banished from the Roman capital. The first Roman surgeon of real merit was Celsus, who flourished at the beginning of the Christian era, who improved the mode of performing lithotomy and amputation, described the operation for cataract, and first recommended the application of ligatures to wounded arteries, for the purpose of arresting hæmorrhage. His works contain an exact representation of surgical knowledge up to his own time. Aretæus of Cappadocia, who practised in Rome during the latter half of the 1st c., was the first to employ blisters, using cantharides (as we still do) for that purpose. Rufus of Ephesus, who lived half a century later, first tied an artery which had become aneurismal in consequence of being wounded in venesection. Galen, who practised in Rome in the latter part of the 2d c., mainly obtained his great reputation by his medical practice. His surgery was confined for the most part to fomentations, ointments, and plasters for external application; to the art of bandaging, and to the employment of complicated machinery in fractures and dislocations. There is little to record for several future centuries. Aëtius, in the 6th c., recommended scarification of the legs in dropsy, tried to dissolve urinary calculi by internal remedies, studied the diseases of the eye, and is the first writer who notices the guinea-worm. Paulus Ægineta, in the 7th c., opened internal abscesses by caustics, improved the operation of lithotomy, described several varieties of aneurism, extirpated the breast, performed laryngotomy and tracheotomy, and was the originator of the operation of embryotomy. His sixth book is regarded as the best body of surgical knowledge previous to the revival of letters. Rhazes, an Arabian, who had charge of a hospital at Bagdad, at the end of the 9th c., was the

first to describe spina bifida, but he did not understand its real nature; he cauterised the bites of rabid animals, and gave a better account of hernia than any of his predecessors. To Avicenna, who lived a century later, we probably owe the first use of the flexible catheter, and of the instrument now generally known as Hey's saw. Albucasis (died 1122) describes an instrument for the cure of fistula lachrymalis, the removal of tumours by ligatures when the knife is inexpedient, the suture of wounded intestines, the use of the probang in obstruction of the gullet, &c., and is the only ancient writer on surgery who describes the instruments used in each special operation. In 1271, Pitard, an eminent surgeon of his time, laid the foundation of the College of Surgeons of Paris. In Great Britain, Gilbertus Anglicanus, who lived about the beginning of the 14th c., is the first known surgical writer; he was shortly followed by John of Gaddesden, author of the *Rosa Anglica*. In the middle of that century, Guy de Chauliac, the first to describe the Cæsarian operation, practised at Avignon; and contemporary with him was John of Ardern, who is regarded as the first surgeon of his time. During the 15th c., the local application of arsenic for cancer was proposed by Taranta, a Portuguese surgeon practising at Montpellier; and lithotomy was removed from the hands of itinerant quacks into the department of pure surgery, by Colot, a surgeon to the French court. Moreover, the College of Surgeons dates from this century, having been founded in 1460—1461; while at the commencement of the next century (1505) the Edinburgh College* was founded. The surgery of the 16th c. may be said to be represented by Ambrose Paré (q. v.). His works, first published in 1535, exerted a most beneficial influence on the profession. Towards the close of this century, Fabricius ab Acquapendente (q. v.), to whom we are indebted for the modern trephine, and for the use of the tube in tracheotomy, published his *Opera Chirurgica*, which passed through 17 editions. Early in the 17th c. (1612), a Scotchman named Lowe published *A Discourse on the whole Art of Chirurgery;* and about fifty years later, Wiseman, who has been appropriately termed 'the Paré of England,' and 'the true father of British surgery,' flourished. He was Serjeant-surgeon to Charles II.; and his surgical works, published in 1676, may still be read with interest. He was the first to dispel the dangerous belief, that gun-shot wounds were of a poisoned nature, and had consequently to be treated with the most painful kinds of dressing. Contemporary with him were James Young of Plymouth, who first performed the flap-operation in amputation; Scultetus (a German), the author of *Armamentarium Chirurgicum;* Frère St Cosme, commonly known as Frère Jacques, a French monk, who considered himself specially commissioned by Heaven to cut for stone, and who has the merit of having converted the tearing into a cutting operation; Rau of Leyden, one of the most successful lithotomists of any age, and a pupil of Frère Jacques; and Roonhuysen, who divided the sternomastoid muscle for wry-neck, and may thus be regarded as the inventor of tenotomy. The 18th c. produced, in England, White, the originator of excision of joints; Cheselden and Douglas, famous as lithotomists; Percival Pott, John Hunter, and Hey of Leeds; in Scotland, Monro, Benjamin Bell, and John Bell; in Ireland, O'Halloran and Dease; in France, Petit and Desault—the former celebrated for his work on Diseases of the Bones, and the latter distinguished for his improvements in surgical instruments of various kinds; in Germany, Richter and the illustrious Haller; and in Italy, Lancisi, Morgagni, and Scarpa. Moreover, in this century (1784) the Royal College of Surgeons in Ireland was founded. Never was surgery so brilliantly represented as during the present century. The London medical schools can point with equal pride to the names of the past generation—to Abernethy, Blizard, Brodie, Astley Cooper, Dalrymple (the oculist), Earle, Guthrie and Hennen (the great military surgeons), Aston Key, Liston, Stanley, Travers, Tyrrell (the oculist), Ware (the oculist), James Wilson, and many other nearly equally celebrated surgeons; and to those of the present—to Arnott, Bowman, Erichsen, Fergusson, Prescott Hewett, Hilton, Lane, Lawrence, Luke, Paget, Spencer Wells, and a host of others, any one of whom would have been pre-eminent a century ago. The Edinburgh schools can boast of Sir Charles Bell, Lizars, Miller, and especially Syme and Simpson (that *par nobile fratrum* of whom any university might well have been proud), the former one of the boldest and most successful of operators, and whose name will be ever associated, in the history of Surgery, with the special amputation of the foot which is known as 'Syme's amputation,' and with the operation for stricture; and the latter claiming a notice in this article as the discoverer of the application of chloroform to surgical practice, and for the introduction of acupressure as a means of checking hæmorrhage. Amongst the past surgical celebrities of Dublin must be mentioned Peile, the inventor of Peile's lithotome and staff; Todd (the father of the late eminent Dr Todd of London), who was the first to successfully revive the treatment of aneurism by compression; Colles, the first to describe the fracture known as Colles's fracture of the radius; Carmichael, distinguished for his opposition to the indiscriminate use of mercury in syphilis; Bellingham, and Hutton, whose names are associated with the full development of the revived treatment of aneurism by compression; Cusack, Porter, M'Dowel, and Sir Philip Crampton; while Adams (well known for his treatise *On the Diseases of the Joints, and Chronic Rheumatism*), R. W. Smith (celebrated for his researches on fractures and neuroma), and Jacob (the discoverer of the *Membrana Jacobi*), still survive. It would be impossible to mention a tithe of the names of those who have attained high surgical celebrity in the provinces during the present century. The Barons Dupuytren and Larrey, and MM. Amussat, Chassaignac, Civiale, Brasdor, Broca, Desmarre (the oculist), Nélaton, Roux, Sichel (the oculist), Velpeau, &c., have honourably sustained the reputation of French surgery. Beer (the oculist), Chelius, Dieffenbach, Von Gräfe (the oculist), Gurlt, Jäger (the oculist), Langenbeck, Stromeyer, and Wützer, constitute but a small portion of the eminent surgeons of Germany. Callisen of Copenhagen, Porta of Pavia, and Pirogoff of St Petersburg, may be taken as the surgical representatives of their respective countries. Amongst American surgeons the names of Valentine Mott, the Warrens, Marion Sims, and Gross deserve special notice. To understand what surgery now is, and to trace its recent progress, the reader should study the standard surgical treatises of Erichsen, Fergusson, Miller, and Syme; and the comprehensive and most valuable *System of Surgery*, edited by Mr Holmes, and contributed to by many of the most eminent authorities

* For much interesting and valuable information regarding this college, the reader is referred to Dr Gairdner's *Historical Sketch of the Royal College of Surgeons of Edinburgh, with Notes and Documents* (Edin. 1860). The same author's *Sketch of the Early History of the Medical Profession in Edinburgh* (Edin. 1864) may also be consulted with advantage.

on surgery. He will also do well to read Fergusson's *Lectures on Conservative Surgery,* and Syme's *Address on Surgery,* delivered before the members of the British Association in August 1865.

With the increase of knowledge, specialities naturally develop themselves; and such has been the case in surgery. The diseases of the eye, the diseases of the ear, the diseases peculiar to women, the diseases of children, and deformities (the treatment of which is termed Orthopædic Surgery), more or less separate themselves, at least in large towns, from general surgery, and constitute special departments, of which dentistry may be considered one; as most of the eminent dentists of the present day are regularly educated and qualified surgeons.

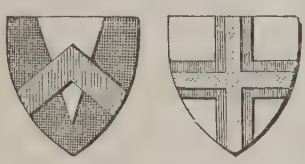
It is deserving of record that within the last few years, nearly all the British universities have commenced to give Surgical as well as Medical Degrees.

For further information on the History of Surgery, the reader is referred to the old histories of Le Clerc (Geneva, 1696) and Freind (Lond. 1725), to Moir's *Outlines of the Ancient History of Medicine,* to Sprengel's voluminous *History of Medicine* (in German), to the admirable 'Historical Notice of Surgery,' in the late Professor Miller's *Principles of Surgery,* and to S. D. Gross's *System of Surgery,* and H. H. Smith's *Principles and Practice of Surgery,* &c., Philada.

SURINA'M. See GUIANA, DUTCH.

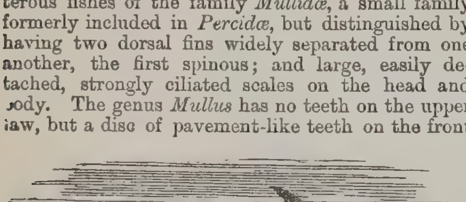
SURINAM BARK. See ANDIRA.

SURMOU'NTED, in Heraldry, a term used to indicate that one charge is to be placed over another



of different colour or metal, as in the annexed figures, which may respectively be blazoned: Sable, a pile argent surmounted by a chevron gules; and, Argent, a cross gules surmounted by another or.

SURMU'LLET (*Mullus*), a genus of acanthopterous fishes of the family *Mullidæ*, a small family formerly included in *Percidæ*, but distinguished by having two dorsal fins widely separated from one another, the first spinous; and large, easily detached, strongly ciliated scales on the head and body. The genus *Mullus* has no teeth on the upper jaw, but a disc of pavement-like teeth on the front



Surmullet (*Mullus surmuletus*).

of the vomer. Two long barbels hang from the under jaw, or, when not in use, are folded up against it. Only two species are known, both abundant in the Mediterranean, and both found on the British coasts. They very generally receive the name MULLET, by which they are confounded with a very different genus. The STRIPED S., or STRIPED RED MULLET (*M. surmuletus*), is sometimes very plentiful on the southern coasts of England, but is rarer towards the north. It approaches the shores in summer, and many surmullets are then taken in mackerel nets; but at other seasons it is only obtained from comparatively deep water by trawl-nets. It sometimes attains, in the Mediterranean, a weight of six or seven pounds, but has never been known much to exceed three pounds in the British seas, and is seldom more than two pounds in weight. The ancient Romans, who held it in the highest esteem, gave prodigious prices for fish of unusually large size. They kept surmullets in their *vivaria*, but there the fish did not increase in size. The colour is pale pink, with three or four yellow longitudinal stripes; but where any of the scales have been rubbed off, beautiful tints of purple and bright red appear, which takes place also during the struggles of the fish when dying, and the Romans were therefore accustomed to bring surmullets alive into their banqueting-rooms, that the guests might see them die, and enjoy the brilliant display of colour, before eating the fish. The liver was regarded as peculiarly delicious, and was bruised in wine to make a *garum* for the flesh. The S. is still regarded as one of the best of fishes.—The RED S., or PLAIN RED MULLET (*M. barbatus*), is very rare on the coasts of Britain. It is a much smaller fish than that already described. Other species of *Mullidæ* are found in tropical seas.

SU'RNAME (either from its being an additional name—Fr. *surnom*, Ital. *sopranome*—or from the practice of writing it over the Christian name, which is to be seen in the court rolls and other ancient muniments), in modern Europe, the family name. The Roman *cognomen* partook somewhat of the same character; but the introduction of the surnames of modern time cannot be traced further back than the latter part of the 10th century. See NAME.

SU'RPLICE (Lat. *super pellicium*, above the robe of fur), a linen or muslin vestment, worn by clerks of all degrees of orders in the discharge of their public religious offices. It is by some supposed to be derived from the longer and more flowing vestment which, in the Roman Catholic Church, is still used in the mass, and is called the 'alb;' but in that church the surplice is worn not alone by priests, but by all who have been admitted even to the church tonsure. Its most ordinary use is for the service of the choir, and it is also employed, along with the stole, by priests in the administration of the sacraments, and in preaching. The use of the surplice was strongly objected to by the Calvinistic and Zwinglian reformers on the continent, and by the Puritans in England, who regarded this vestment as a relic of popery, and made it the subject of vehement denunciations. The argument against it is to be found in Beza, *Tractat. Theolog.*, iii. 29, and its defence in Hooker's *Ecclesiastical Polity,* book v., ch. 29. Within the last twenty years, no little stir has from time to time been created by the use of the surplice by the preacher in the pulpit, contrary to the more general practice in the Anglican Church. Preaching in the surplice has been associated in the popular mind with a Romanising tendency, although it is difficult to say on what basis this association rests.

SU'RREY (Sax. *Suth-rice*, the south kingdom), an inland county in the south of England, bounded on the north by Middlesex, and on the east by Kent. Area, 478,792 acres; pop. (1881) 1,435,842. The middle of the county is traversed from west to east by a well-marked ridge of the North Downs, which

rises in Botley Hill, above Titsey, to the height of 880 feet. On the north side of this range, the land slopes gradually to the banks of the Thames, which runs along the northern border; but on the south side, the descent is rugged and broken, affording pleasing and sometimes romantic scenery. South of the main range, and about four miles south of Dorking, is Leith Hill, 993 feet high, the most important elevation in this quarter of the country. Stretching along the southern bank of the Thames, and extending over a space about six miles in breadth, is a tract which belongs to the London clay formation; further south, and likewise extending from west to east, there is a tract of plastic clay, varying in breadth from one to five miles. Chalk, weald clay, and iron-sand formations occupy the south of the county. The principal streams are the Mole and Wey, tributaries of the Thames. The soil of the northern half of the county is fertile; in the west and south-west, the land is, to a great extent, covered with heath. The climate is soft and mild in low-lying districts, and is favourable to the production of corn and grass. More than four-fifths of the entire area is under culture. In the north, in the vicinity of London, there are numerous market-gardens, the produce of which is sent to supply the markets of the metropolis. Hops, wheat, and the ordinary crops are raised. The county contains much wood, and the beauty of the scenery, and the facility of communication with London, have attracted many residents to S., which is consequently studded over with mansions and villas. Manufactures are carried on in Southwark and in the other southern suburbs of London, as well as in Croydon, Guildford, Kingston, and Reigate, which are the principal towns. The county returns four members to the House of Commons.

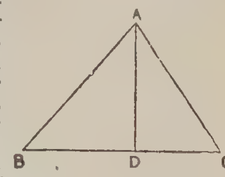
SU'RTURBRAND, a kind of Brown Coal (q. v.) found in the north of Iceland, and there used for fuel. It has a great resemblance to the black oak found in bogs. It is capable of being made into tables and other articles of furniture, but is too brittle to be cut into shavings by a plane.

SURVEY'ING. Land surveying may be considered the earliest practical application of the art of geometry or earth measurement, and must have been in some more or less rude form coeval with agriculture and the division or appropriation of the soil. In Rome, surveying was considered one of the liberal arts, and the measurement of lands was intrusted to public officers who enjoyed certain privileges; and it is probable that the system of measurement practised by them was very similar to our plain surveying with the chain and cross staff of the present day, and has been handed down to us through the feudal period. An examination of ancient records and title-deeds will shew that both areas and boundary-lines of the different enclosures forming fields, hundreds, town-lands, &c., are often laid down with a considerable degree of accuracy.

Land surveying may be considered under the following heads: (*a.*) Plain surveying with the chain, and without the aid of angular instruments, except the cross staff or fixed angle of 90°. (*b.*) Modern engineering surveying, in which angular instruments are used. (*c.*) Coast and military surveying. (*d.*) Trigonometrical surveying (q. v.).

The fundamental rule of every description of land surveying, from the humble attempt of the village schoolmaster to lay down an irregular garden plot, to the trigonometrical survey of a large extent of the earth's surface, when the aid of the most refined improvements of modern science is indispensable, is simply to determine three elements of a triangle, and thence to calculate its area.

In plain surveying with the chain, the three sides of the triangle, ABC, are supposed to be accessible, and are carefully measured on the ground, and then laid down or platted to scale on paper, when an accurate figure of the triangle will be obtained, on which the length of the sides can be marked. To get the area, however, it will be necessary to determine the length of the perpendicular line AD, and this is usually done (when possible) on the ground by means of a simple instrument called a cross, which consists of two sights or fine grooves at right angles to each other, and being placed on the line BC (keeping B and C visible in one of the sights), nearly opposite the angle A, is moved gradually till the angle A is intersected by the other sight. The line AD can be also laid down on the drawing, and its length found by scale, and afterwards verified on the ground, or it may be at once laid down on the ground by the use of the chain alone. An improved reflecting instrument, called an optical square, is also often used for this purpose. Any boundaries along the lines or sides of the triangle, ABC, can be determined by the use of Offsets (q. v.) or insets, as they occur on right and left of line. No matter what the form of the surface to be surveyed may be—polygon, trapezium, or trapezoid—it may thus be determined by a judicious subdivision into triangles; and when the survey is not of a very extended nature or character, and when no serious obstructions exist, chain surveying is both accurate and expeditious, especially if proof or tie lines are properly introduced, for the purpose of testing the accuracy of the work.

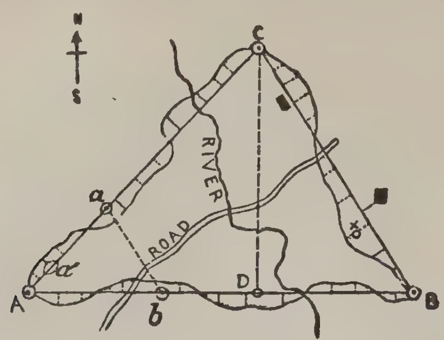


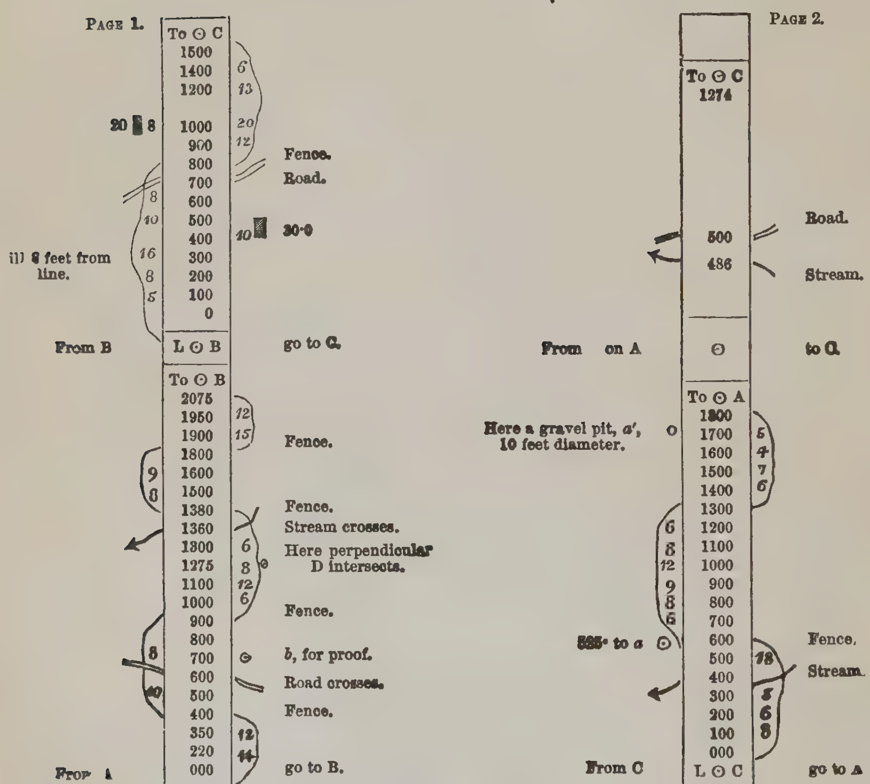
In every description of surveying, it is best to make the original triangle as large as possible, and to work from a whole downwards, rather than build up a large triangle by the addition of several small ones. It would be impossible here to lay down rules to meet the many difficulties which arise in the practice of surveying, and indeed the best test of a good surveyor is the ease with which he will overcome local obstructions, which appear almost insurmountable to a novice, or even to a theoretical surveyor with little field practice.

Where buildings or other impediments are found in the measurement of a straight line, they are generally passed by the erection of short perpendiculars sufficient to clear the obstacles, and a line parallel to the original measured as far as they exist, when the original line can be again resumed. Differences of level, occurring in measuring a line where no instruments are used, are generally compensated or allowed for by the judgment of the surveyor.

In registering the dimensions taken on the ground, such as sides of triangles, offsets, intersections of roads, fences, &c., and everything necessary to make a perfect delineation or plan of the surface, surveyors use what is called a field-book, the mode of keeping which varies very much with individual practice. Some surveyors use hand sketches or rough outlines of the form of the ground, and mark the dimensions on them, while others use the ordinary form of field-book, or a combination of the two methods, which perhaps is the best when any difficult complications happen on the ground, such as the frequent occurrence of buildings, enclosures, water, &c. along the line. In the ordinary field-book, the centre column, commencing from the bottom, represents the length of any line or side of a triangle; and the figures in the column, the distance at which the offsets to the right or left are taken, or where roads

streams, fences, &c. cross the line, or buildings adjoin the same. We give below the field-book of the assumed survey of the triangle ABC, with the different offsets and insets on its sides, and where roads, fences, streams, &c. cross them, the detail of which can be obtained by subdividing the triangle





The line *ab* may be similarly booked and platted, and any lines intersecting shewn.

into smaller internal ones. The figure can thus be laid down from the book, and its area calculated by the formula $\frac{AB \times CD}{2}$, and the offsets and insets calculated, added, or deducted, by the methods given in OFFSETS.

Ponds, plantations, and enclosures of different kinds may be surveyed with a chain, especially if their form be such that they can be conveniently included in the area of a triangle, the correctness of which, being proved by proper tie-lines, the form, area, &c. may be ascertained by offsets, or rather insets from the sides.

SÛRYA is, in Hindu Mythology, the god of the sun. His wife is, in later mythology, *Sûryâ*, who, in order to escape his embraces, transformed herself into a mare, but nevertheless became the mother by him of the twin *As'wins*, afterwards the heavenly physicians. Besides Sûryâ, he had several other wives, by one of whom, *Sanjnâ*, he begot Yama, the god of death, and the river Yamunâ, or Jumna. By Kuntî, before her marriage with Pân'd'u (q. v.), he had *Karn'a*, who, therefore, was an elder brother of the Pân'd'u princes, but in the conflict between the Pân'd'us and the Kurus, sided with the latter, and was killed by Arjuna. S. became also, by his other progeny, the ancestor of a royal dynasty, called after him *Sûryavans'a*, or the solar race. S. is represented with a lotus-flower in his hand, on a

chariot drawn by seven horses, and conducted by his charioteer Arun'a, the god of the dawn, who is represented without legs.

SU'SA (Shushan in Daniel, Esther, &c., derived by some from Shoshan, a lily), probably the modern Sus or Shusn, in lat. 32° 10′ N., and long. 48° 26′ E., situated between the Chapses or Eulæus (Ulai in Daniel), and the Shapur, anciently the capital of Susiana (the *Elam* of Scripture, mod. *Khusistan*), and one of the most important cities of the old world. Its foundation is variously ascribed by ancient writers to Darius Hystaspes, or to Memnon, the son of Tithonus; and its name, together with its ground-plan, is traced on Assyrian monuments at the time of Assur Bani Pal, about 660 B. C. At the time of Daniel's vision 'at Shûshan in the palace,' it was under Babylonian dominion, but came, at the time of Cyrus, under Persian rule; and the Achæmenian kings raised it to the dignity of a metropolis of the whole Persian Empire, and as such Æschylus, Herodotus, Ctesias, Strabo, &c. speak of it. At the Macedonian conquest it was still at its height, and Alexander is reported to have found in it vast treasures, together with the regalia. On Babylon becoming the principal city of Alexander and his successors, S. gradually declined, but seems still to have contained enormous wealth at the time of its conquest by Antigonus (315 B.C.). It was once more attacked by Molo in his rebellion against Antiochus the Great; and during the Arabian conquest of Persia it held out bravely for a long time, defended by Hormuzan. The ruins of its ancient buildings, the palace described in Esther among them, cover a space of about three miles. The principal existing remains consist of four spacious artificial platforms above 100 feet high. Traces of a gigantic colonnade were laid bare by Mr Loftus, with a frontage of 343 feet, and a depth of 244. Cuneiform inscriptions exist, together with many other relics similar to those found at Persepolis (see PERSEPOLIS; compare also CUNEIFORM). The 'tomb of Daniel' shewn near S. is a modern Mohammedan building.

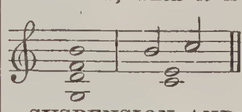
SU'SA, a city of Northern Italy, province of Turin, stands on the right bank of the Dora Riparia, at the foot of the Cottian Alps, 32 miles west of Turin. It is an episcopal see, and has a cathedral consecrated in 1028, with a baptistery of one single block of green marble. Among its other notable buildings are the episcopal palace, the town-hall, and the Borgo de' Nobili. The surrounding country produces wines, fruits, mulberry trees, and wood. The road over Mont Cenis, opened in 1810, begins at Susa. Pop. 4989.

S., called by the Romans *Segusio*, is a very ancient city; it was founded by the Celts, and was in the reign of Augustus the capital of the Celtic chief Cottius, from whom the Cottian Alps received their name, and during the empire was the starting-point for crossing Mont Cenis. A triumphal arch, erected by Cottius in honour of Augustus, still remains.

SUSA'NNAH, HISTORY OF, *The Judgment of Daniel*, also *Susannah and the Elders*, are the different titles of a well-known story, which forms one of three apocryphal additions to the Book of Daniel; the other two being *The Song of the Three Holy Children*, and *The History of Bel and the Dragon* (q. v.). It relates how S., the wife of Joiachim, and daughter of Hilkiah, celebrated alike for her beauty and her virtue, was falsely accused of adultery by certain 'lovers' whose advances she had spurned; and how, being condemned to death on their evidence, she was saved by the wise Daniel, who tore the mask from her enemies, and caused them to experience the fate they had designed for her. The question—not a very important one certainly—has been much debated, both in the early and later times of the church, whether or not the story of S. is true; and arguments (of various weight) have been adduced to shew that the book is a fabrication, a fable, a legend, and a history. The most probable view, perhaps, is that which regards it as a tradition of something that did happen in the life of Daniel, but which has been moulded into a moral fiction by the hand of a literary artist. The original is believed to have been Greek and not Hebrew. In most MSS. it precedes the first chapter of the Book of Daniel, and so we find it in the old Latin and Arabic versions; but the LXX., the Vulgate, the Complutensian Polyglot, and the Hexaplar Syriac, place it at the end of the present book, and reckon it as the 13th chapter.

SUSPE'NSION, in Music. A note is said to be suspended when it is continued from one chord to another to which it does not properly belong, and to a proper interval of which it must eventually give way. Thus we have here the note G extended from the first chord into the second, in which it is first suspended, and then resolved into the chord FACF:

This example is a suspension from above, in which a descent is necessary for its resolution: but a note may also be suspended from below, when it is resolved by an ascent:



SUSPENSION AND INTERDICT, in Scotch Law, is a process by which the suspender, who initiates the proceeding, seeks to stop or interdict some act, or to prevent some encroachment on property or possession, or in general to stay any unlawful proceeding. The first step is to present a note of suspension and interdict to the Lord Ordinary, who grants *interim* interdict either with or without caution, and orders the note to be answered, or refuses interdict. When the note is answered, the Lord Ordinary passes or refuses the note, and continues or recals the interdict as the case may be.

SUSPENSION BRIDGES. In these bridges, the roadway is suspended from chains passing over piers or towers, and firmly fixed at their extremities. Fig. 1 is a sketch of an ordinary

Fig. 1.

suspension bridge. When the roadway is equally loaded over its length, the curve of the chain is a parabola. The weight of the roadway being

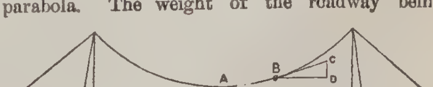


Fig. 2.

known, the strain upon the chain, and its requisite strength, are readily determined. For example, in Fig. 2, if A be the centre of the bridge, and it be

required to find the strain upon the chain at the point B, it is evident that the weight of the roadway between A and B is supported by the chain at B; we have then to find what strain in the direction of the length of the chain, will support this vertical load. By the principles of mechanics, if we draw a right-angled triangle BCD, of which the side BC is a tangent to the curve at B, CD is vertical, and BD horizontal; and if the length of CD represent numerically the load on AB, then BC will represent numerically the strain on the chain produced by that load, and BD will be what is called the horizontal component of this strain. This horizontal part of the strain is the same for every part of the curve; it is the total strain on the chain at the centre A, and the strain carried over the towers and balanced by the backstays, which are firmly anchored to the ground behind them. In this manner the conditions of strength and stability of a bridge uniformly loaded are easily determined, but when we have a rolling load which is heavy in proportion to the weight of the bridge, as for example a railway train, the case is very different, for when the train only occupies one half of the bridge, the chain will be depressed towards that side, and raised at the centre; thus an undulation will be produced in the bridge, which, if the train be moving rapidly, would endanger its stability. Various combinations have been devised to overcome this difficulty. The most simple, and practically the best, is to stiffen the roadway so that the strain of the passing load is distributed over a considerable length of the chain. In this manner, large railway bridges have been constructed in America; among them is that over the Niagara above the Falls, with three lines of rails on it, of which the span is 822 feet, and the height of the platform above the river 250 feet; it is supported by four wire cables each containing 3640 wires. Trains pass over it at the rate of 10 miles per hour. Other plans have been devised for stiffening these bridges, such as stiffening the chain itself, and rendering it rigid; also by using a number of chains, so that one of them may always be in a condition to carry the load without alteration of form. But these methods are bad in principle, and do not give results at all in proportion to their expense. The proper and legitimate use of suspension bridges is to carry ordinary roads over large spans, where the rolling loads are not great in proportion to the weight of the bridge itself, and not very rapid in their motion. Many beautiful examples are to be seen in Great Britain, among others we may instance the Menai Bridge, 580 feet span, and the Clifton Bridge, near Bristol, recently opened, 703 feet span.

SUSPENSION OF ARMS. See TRUCE.

SUSQUEHA'NNA, an American river, which has its origin in Otsego and Canandaigua Lakes, in western New York, and flowing eastward, receives the rivers Unadilla and Chenango, then, turning south, enters Pennsylvania, where it receives the Pittston, the Tioga, the West Branch, and the Juniata, and empties itself into the Chesapeake Bay, at Havre de Grace, Maryland, 400 miles from its source, and 153 from its junction with the West Branch. It is a shallow, rapid, mountain river, with varied and romantic scenery. A canal follows its course, and great quantities of timber are floated down in the spring freshets. Near the mouth, it is famous for waterfowl, especially the Canvasback Duck, and has important fisheries.

SUS'RUTA is one of the great medical authorities of ancient India. See *Medicine*, under SANSKRIT LITERATURE. His work is called *Âyurveda*, and consists of six books. It was edited by Srî Madhusûdana Gupta, in 2 vols. (Calcutta, 1835—1836).

SU'SSEX (South-Saxons), a maritime county in the south of England, bounded on the N. by Surrey and Kent, on the S. by the English Channel, and on the W. by Hampshire. Area, 936,911 acres; pop. (1881) 490,316. The South Downs (see DOWNS) traverse the county from west to east, ending about 20 miles east of Brighton, in the lofty cliff of Beachy Head. The northern escarpment of the Downs is precipitous, but leads down to the fertile and richly wooded district of the Weald (see DOWNS). A remarkably productive tract, from two to seven miles in breadth, extends west from Brighton along the coast to the Hampshire border; and in the south-east of the county the rich marsh lands that line the coast, and which are 30,000 acres in extent, make excellent pasture-grounds. Of the Down-land there are about 50,000 acres, covered with a fine, short, and delicate turf, on which the well-known breed of Southdown sheep, to the number of 300,000, are pastured. Of the Weald district, which formerly was covered with dense forests, there are within the county 425,000 acres; a considerable tract has been brought under cultivation. Irrespective of the less productive districts, there are in the county 120,000 acres of rich arable land; 150,000 acres are occupied by woods, which abound chiefly in the Weald, and in the Forest Ridge in the north-east of S., where are St Leonard's Forest (10,000 acres), and Ashdown Forest (18,000 acres). The chief rivers are the Arun, Adur, and Ouse, which have their origin in the north of the county, and flow south into the Channel. In the south of S. the climate is mild, and several large towns (see BRIGHTON and HASTINGS) are largely resorted to by those who seek health or relaxation. Seaford and Pevensey Bays are much frequented by vessels, and the east portion of the coast is defended by martello towers. The county has for centuries been divided into the six rapes of Lewes, Pevensey, Hastings, Chichester, Arundel, and Bramber. The county returns four members to parliament. Capital, Chichester.

SUSTENTA'TION FUND, a fund provided in the Free Church of Scotland for the support of the ministers of the church. The idea of such a fund was probably derived by Dr Chalmers from the system of the Wesleyan Methodists, and a scheme devised by him was made public before the Disruption, so that arrangements had been made, and a small sum already collected, when that event took place. The scheme was afterwards carried into operation throughout the whole of Scotland, and continues unmodified to the present time. The members of the church are called upon to contribute, according to their own will and ability, to a common fund; of which, after payment of expenses, payments to a fund for widows and orphans, pensions to retired ministers, &c., an equal division is made among the ministers of the church, with a few exceptions, chiefly in the case of newly formed congregations. The amount of the fund has gradually increased from £68,704 in 1843—1844, to £152,112 in 1873—1874. but the dividend from the fund has never quite reached the sum of £150, which has long been aimed at as its desired minimum, the number of congregations having increased. Congregations are permitted to supplement the stipends of their own ministers, and if able are expected to do so. The supplement in some congregations in towns much exceeds the dividend from the fund; but in many parts of the country, the whole, or almost the whole, stipends of the ministers are derived from it. The question has been much discussed, whether so

equal dividend ought to be made, or a proportion established between the liberality of a congregation and the amount paid to its minister. The subject of the Sustentation Fund is of interest not only to the Free Church of Scotland, but to all unendowed churches.

SU'THERLAND, a county in the extreme north of Scotland, is bounded on the E. by Caithness and the North Sea, on the N. and W. by the Atlantic, and on the S. by Ross and Cromarty. Area, 1,207,188 acres; pop. (1881) 23,370, or 12½ per square mile. The coast-line is 60 miles in extent; and the shores, rugged on the north and west, where they are broken by the force of the Atlantic, are comparatively flat on the east. The southern and central regions of S. are the most elevated; and rivers, mostly from the middle of the county, flow east and south-east to the North Sea, and north, north-west, and west to the Atlantic. The principal mountain peaks are Ben More in Assynt (3431 feet), and Ben Klibert (3164 feet). The chief rivers are the Oikel and the Shin—which, with other affluents, unite to form Dornoch Firth—the Brora, Helmsdale Water, and Naver. Extensive moors, the haunt of herds of red deer, stretch across the county; and the rivers and lakes, the chief of which is Loch Shin (q. v.), form numerous low-lying valleys or straths. In the interior and western districts, the climate is cold, and the county is often deluged with continuous rains; but in the eastern districts, the climate is mild, and the soil very fertile in all agricultural produce. In 1868 there were 23,148 acres under crops, of which 8510 acres were under corn, 4180 acres green crops, 5727 clover and other artificial grasses, and 4491 acres permanent pasture. The number of cattle in the same year was 10,794; sheep 221,-613, and swine 1210. In 1868 traces of gold were found in a burn in S., but, though the metal was of excellent quality, the amount was hardly sufficient to repay the labour of the 'diggers.' Granites of various colours, marble, limestone, &c., are found; but these are comparatively valueless on account of their remote situation. Manufactures are inconsiderable. Salmon-fishings are of very considerable value; and the white and herring fishings employ many boats. S. is well supplied with churches; two-thirds of the inhabitants belong to the Free Church, and one-third to the Established Church. The schools are well attended, and a knowledge of English is rapidly spreading, while the Gaelic language is dying out. The whole of the county, except one-twentieth part, belongs to the Duke of Sutherland.

S. received its name from the Northmen, who frequently descended upon and pillaged it prior to the 12th c., and called it the Southern Land, as being the limit on the south of their settlements. The condition of the people of S. before 1811, in which year the county began to be opened up by roads, was miserable. Their sustenance, dependent mostly upon their half-starved flocks, was very precarious, and would have failed them often had not charity administered relief. A former Duke of Sutherland effected what are known as the 'Sutherland Clearances,' by compelling such of his tenants as could not support themselves, owing to the unsuitability to agricultural purposes of the districts upon which they dwelt, either to remove to more fertile districts, where they received land at a merely nominal rent, or to emigrate at his expense to Canada.

SU'TLEJ, or SUTLUJ, an important river in the north-west of India, the eastmost of the five rivers of the Punjab, rises in the sacred lakes of Manasarovara and Rawan-Hrad in Thibet, lat. 30° 45′ N., long. 81° 15′ E. At its outfall from Lake Manasarovara, at between 19,000 and 20,000 feet above sea-level, it is a rapid torrent 30 feet broad. It flows north-west for 150 miles, when turning to the south-west it receives the Spiti or Li, a larger stream than itself. The Spiti is 8592 feet above sea-level, when it joins the S., and the scene of the confluence of the two rivers is sublime in the highest degree. Continuing a south-west course, the S. breaks through the mountain-rampart of the Himalaya, and after flowing in all about 850 miles, in the course of which it is joined by the Beas and the Chenab, it fall into the Indus in lat. about 29° N. Its upper course is supposed to be identical with the Hesudrus, and its lower course (in which it is called the Ghara) with the Hyphasis of the ancients.

SU'TLER is a vendor of provisions allowed by the Quartermaster-general to follow an army in the field, for the purpose of supplying the soldiers with such luxuries as they can afford to purchase. Sutlers are under martial law, accompany the baggage on a march, and are narrowly watched, and severely punished if found guilty of any irregularities towards either the soldiers or inhabitants of the country. In the French army a soldier in each regiment is licensed to act as sutler, and is called *vivandier*. See also CANTEEN.

SÛTRA (from the Sanscrit *siv*, to sew, literally therefore, a thread or string) is, in Sanscrit Literature, the technical name of aphoristic rules, and of works consisting of such rules. The importance of the term will be understood from the fact, that the *groundworks* of the whole ritual, grammatical, metrical, and philosophical literature of India are written in such aphorisms, which therefore constitute one of the peculiarities of Hindu authorship. The object of the Sûtras is extreme brevity; and, especially in the oldest works of this class, this brevity is carried to such an excess, that even the most experienced would find it extremely difficult, and sometimes impossible, to understand these aphorisms without the aid of commentaries, which, however, are fortunately never wanting, wherever a work is written in this style. Though there is no positive evidence as to the cause or causes which gave rise to this peculiarity of Hindu composition, the method of teaching in ancient India—an account of which is afforded in some of the oldest works—renders it highly probable that these Sûtras were intended as memorial sentences which the pupil had to learn by heart, in order better to retain the fuller oral explanation which his teacher appended to them. But it is likewise probable that this method of instruction itself originated in the scarcity or awkwardness of the writing material used, and in the necessity, therefore, of economising this material as much as possible; for that writing was known and practised at the remotest period of Hindu antiquity, is now placed beyond a doubt, though a startling theory was propounded, some years ago, to the effect that writing was unknown in India, even at the time of the great grammarian Pân'ini. The manner, however, in which, up to this day, the Hindus are in the habit of keeping the leaves of their books together, seems to throw some light on the name given to this aphoristic literature. The leaves—generally narrow, and even at the present time often being dried palm leaves, on which the words are either written with ink or scratched with a style—are piled up, and, according to the length of the leaves, pierced in one or two places, when, through the hole or holes, one or two long *strings* are passed to keep them together. The name of Sûtra was probably, therefore, applied to works, not because they represent a thread or string of

rules, but on account of the manner in which these works were rendered fit for practical use; just as in German a volume is called *Band*, from its being 'bound.' That a habit deeply rooted outlives necessity, is probably also shewn by these Sûtra works; for while the oldest works of this class may be called Sûtras by necessity, there are others which convey the suspicion that they merely imitated the Sûtra style after the necessity had passed away, more especially as they do not adhere to the original brevity of the oldest Sûtras; and the Sûtras of the Buddhists (see PIT'AKA), conspicuous for their prolixity, could scarcely lay claim to the term, if compared with the Sûtra of the Brahmanical literature.

SUTTEE' (an English corruption from the Sanscrit *satî*, a virtuous wife) means the practice which prevailed in India, of a wife burning herself on the funeral pile, either with the body of her husband, or separately, if he died at a distance.

The practice of suttee is based by the orthodox Hindus on the injunctions of their S'âstras, or sacred books, and there can be no doubt that various passages in their Purân'as (q. v.) and codes of law *countenance* the belief which they entertain of its meritoriousness and efficacy. Thus, the *Brahma-Purân'a* says: 'No other way is known for a virtuous woman after the death of her husband; the separate cremation of her husband would be lost (to all religious intents). If her lord die in another country, let the faithful wife place his sandals on her breast, and, pure, enter the fire. The faithful widow is pronounced no suicide by the recited text of the R'igveda.' Or the code of *Vyâsa:* 'Learn the power of that widow who, learning that her husband has deceased, and been burned in another region, speedily casts herself into the fire,' &c. Or the code of *Angiras:* 'That woman who, on the death of her husband, ascends the same burning pile with him, is exalted to heaven, as equal in virtue to Arundhatî (the wife of Vasisht'ha). She who follows her husband (to another world) shall dwell in a region of joy for so many years as there are hairs on the human body, or 35 millions. As a serpent-catcher forcibly draws a snake from his hole, thus drawing her lord (from a region of torment), she enjoys delight together with him. The woman who follows her husband to the pile expiates the sins of three generations on the paternal and maternal side of that family to which she was given as a virgin. . . . . No other effectual duty is known for virtuous women, at any time after the death of their lords, except casting themselves into the same fire. As long as a woman (in her successive transmigrations) shall decline burning herself, like a faithful wife, on the same fire with her deceased lord, so lóng shall she be not exempted from springing again to life in the body of some female animal. When their lords have departed at the fated time of attaining heaven, no other way but entering the same fire is known for women whose virtuous conduct and whose thoughts have been devoted to their husbands, and who fear the dangers of separation.' See for other quotations, H. T. Colebrooke, *Digest of Hindu Law*, vol. ii. p. 451, ff. (Lond. 1801); and his 'Essay on the Duties of a Faithful Hindu Widow,' reprinted from the *Asiatic Researches*, in his *Miscellaneous Essays*, vol. i. (Lond. 1837). But however emphatically these and similar passages recommend a wife to burn herself together with her deceased husband, it should, in the first place, be observed, that *Manu*, who, among legislators of ancient India, occupies the foremost rank, contains no words which enjoin, or even would seem to countenance, this cruel practice; and, secondly, that no injunction of any religious work is admitted by the orthodox Hindus as authoritative, unless it can shew that it is taken from, or based on, the revealed books, the Vedas (see S'RUTI). An attempt has of late years been made by Râjâ Râdhakânt Deb, to shew that, in a text belonging to a particular school of the Black Yajurveda (see VEDA), there is really a passage which would justify the practice of suttee; but in the controversy which ensued on this subject between him and the late Professor H. H. Wilson, it clearly transpired that the text cited by the learned Râjâ is of anything but indubitable canonicity; moreover, that there is a verse in the R'igveda which, if properly read, would enjoin a widow not to burn herself, but, after having attended the funeral ceremonies of her husband, to return to her home, and to fulfil her domestic duties; and it seems, at the same time, that merely from a misreading of a single word of this verse from the R'igveda, that interpretation arose which ultimately led to a belief and an injunction so disastrous in their results. See H. H. Wilson, 'On the Supposed Vaidik Authority for the Burning of Hindu Widows, and on the Funeral Ceremonies of the Hindus,' reprinted from the *Journal of the Royal Asiatic Society*, vol. xvi., in his Works, vol. ii., edited by Dr Rost (Lond. 1862). That an immense number of widows have fallen victims to this erroneous interpretation of the oldest Vedic text, is but too true. Some thirty years ago, however, the East India Company took energetic measures to suppress a practice which it was perfectly justified in looking upon as revolting to all human feelings, and which it would have likewise been entitled to consider as contrary to the spirit of the Vedic religion. This practice may now be said to have been successfully stopped; for though, from habit and superstition, even now-a-days cases of suttee occur, they are extremely rare; and all reports agree that the enlightened natives everywhere, except, perhaps, in certain native states, support the action of government to repress this evil of bygone times.

SUTURE (Lat. *sutura*, a seam) is a term employed both in Anatomy and Surgery. In anatomy, it is used to designate the modes of connection between the various bones of the cranium and face. A suture is said to be *serrated*, when it is formed by the union of two edges of bone with projections and indentations (like the edge of a saw) fitting into one another. The coronal, sagittal, and lambdoidal sutures (see SKULL) are of this kind. A suture is termed *squamous*, when it is formed by the overlapping of the bevelled (or scale-like) edges of two contiguous bones. There are also the *harmonia* and the *schindylesis* sutures, the former being the simple apposition of rough bony surfaces, and the latter being the reception of one bone into a fissure of another.

In surgery, the word suture is employed to designate various modes of sewing up wounds, so as to maintain the opposed surfaces in contact. As it may fall to the lot of any person, on an emergency, to have to sew up a wound, the following general rules, applicable to all forms of suture, should be attended to. In passing the needle, the edges of the wound should be held in contact with the forefinger and thumb of the left hand; and the needle should penetrate the surface at about an angle of 50° (rather more than half a right angle), and should, at least, pass through the whole thickness of the skin at each stitch. The distance from the edge of the wound at which each stitch should enter and leave the skin, must vary with the depth of the wound; but there should never be less than the eighth of an inch between the margin of the wound and the entrance or exit

of the needle. Sutures should not include vessels, nerves, muscles, or tendons. The line of the thread should cross that of the wound at right angles.

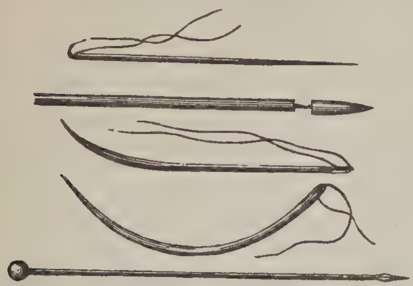

Fig. 1.

For incised wounds on the surface of the body, when the edges can only be transfixed from the cutaneous surface, or when the opposite margins can both be traversed by one plunge, a curved needle (such as a common packing-needle) is most convenient, whereas a strong straight needle is more convenient for the completely free margins of extensive wounds, such as are left after amputation. Fig. 1 represents various forms of needles used by surgeons; fig. 2 shews the *twisted suture*, as used in the operation for hare-lip, in which the wound is transfixed by pins, around which, beginning with the uppermost, a thread is twisted, in the form of the figure 8.

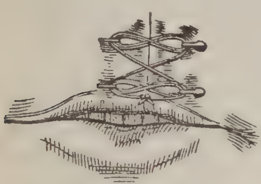

Fig. 2.

SUVOROF, Alexander Vassilivitsh, Count, Prince Italiiski, a Russian field-marshal, and the most famous of Russian generals, was descended from a family of Swedish origin, and was born in Finland, November 13 (O. S.), 1729. His father, who was an officer of the Russian army, and rose, in after-times, to the rank of general and senator, enrolled young S., at the age of 13, in the Semenof regiment, where he remained till 1754, when he was promoted to the grade of lieutenant. S. was present in the Russian army engaged in the Seven Years' War (q. v.), and for distinguished behaviour at Kunersdorf, received the grade of colonel. By a constant succession of eminent services in the Polish civil war (1768), in the war against the Turks (1773—1774), in suppressing internal disturbances, and in subduing the Tartars of the Kuban (1783), he continued to grow in reputation, and rose to the rank of general. In the Turkish war (1787—1792) he was commander-in-chief, for the first time brought the bayonet prominently into use in the Russian army, and decided by it the bloody battle of Kinburn (1787), which would otherwise have been a total rout. At the siege of Otchakof (1788), where he narrowly escaped being made prisoner, the battle of Fokshany (August 1, 1789), which he gained in conjunction with the Austrians, and the decisive victory of Rymnik (September 22, 1789), his headlong bravery, and peculiar system of rapid and repeated attack by overwhelming numbers, secured him complete success. For this last victory, which saved the Austrians under Coburg from annihilation or capture, S. was created, by the Emperor Joseph II., a count of the empire, and from his own sovereign received the title of Count *Suvorof-Rymnikski*. His last great achievement, and the one which has given a predominant colouring to S.'s reputation in Western Europe, was the capture of Ismail (q. v.). S.'s report of his success was couched in the following terms, 'Glory to God and Your Excellency; the town is taken; I am in it.' He was then appointed (1791) governor of the newly conquered provinces; was afterwards sent (1794) to complete the annihilation of the Polish monarchy, which he effected by repeated victories over the Polish armies, the capture of Praga by storm, and the *repossession* of Warsaw (November 19), where a horrible massacre of the inhabitants took place. The grade of field-marshal, and presents of rare value, rewarded these successes. Under Paul, he fell into disgrace (1798), from his impatience of the emperor's fantastic military regulations, and was deprived of his rank; but being restored through English influence, he commanded the Russian auxiliary army sent to co-operate with the Austrians in Italy. In April 1799, he reached Verona; compelled Moreau to retire behind the Adda with immense loss, including more than 8000 prisoners; entered Milan in triumph (April 29); again defeated the French under Macdonald, after a desperate three days' conflict, at the Trebbia (June 17—19), and a third time at Novi (August 15), depriving them of the whole of Northern Italy. His campaign in Switzerland, which promised to bring him face to face with Massena, then the best general in Europe, was rendered abortive by the tardiness of the Austrians, and the Russians, in spite of S.'s remonstrances, were soon after recalled. His escape from the Schackenthal, where he was hemmed in by the French, is considered by many to be the most brilliant and daring retreat ever executed. While on his return to St Petersburg, where a brilliant reception was awaiting him, he fell dangerously ill in Lithuania, and though, on his recovery, he found himself a second time in disgrace, he continued his route, and arrived privately in the capital, where he died sixteen days afterwards, May 17, 1800. His remains were honoured with a magnificent funeral, and the czar Alexander erected a statue to his memory on the Champ-de-Mars. This most extraordinary man had naturally a weak constitution, but rendered it almost invulnerable by exercise, strict temperance, and the regular use of cold baths. His mode of life was of Spartan simplicity, and though the oddity of many of his habits seemed only calculated to encourage ridicule, they, in combination with his paternal care of his men, gave him a powerful hold on the affections of an army at once so ignorant and so thoroughly national in sentiment as the Russian. S. was inflexible in his resolutions and promises, and of incorruptible fidelity. His skill as a general has often been doubted, on the strength of his favourite remark, that all military tactics could be expressed in three words, *stoupai i bi*, 'forward and strike;' but his career shews him to have been possessed of all needful military knowledge—though he hated idle manœuvring—and to have excelled in promptitude and ingenuity of conception, and boldness and rapidity of execution.

SU'ZERAIN (Fr., from Lat. *supremus*), a feudal lord. According to the feudal system, as developed in Northern Europe, every owner of Allodial (q. v.) lands was compelled to acknowledge himself the vassal of a suzerain, and do homage to him for his lands. The term was applied less to the king than to his vassals, who had sub-vassals holding of them.

SWALE. See Yorkshire.

SWALLOW (*Hirundo*), a Linnæan genus of birds

of the order *Insessores*, and tribe *Oscines*, related to the *Tanagridæ*, of several genera forming the family *Hirundinidæ*. This family consists of birds which prey on insects, catching them in the air, and have great powers of flight, now soaring to a great height, now skimming near the surface of the ground or of the water, and wheeling with great rapidity. The bill is short and weak, very broad at the base, so that the gape is wide; the wings are very long, pointed, and more or less sickle-shaped when expanded; the legs are short and weak, and in some —the Swifts (q. v.)—more so than those of any other birds. The tail is generally forked. The plumage is close and glossy. The species are very numerous, and widely diffused, being found in almost all countries. Such of them as occur in the colder parts of the world are summer birds of passage, migrating to warmer regions when winter approaches and insects disappear. The family is divided into two groups, *Swifts*, which have remarkably long and curved wings, very small weak legs and short toes, the hinder toe generally directed forwards, and *Swallows*—some of which are also called *Martins*—having wings not quite so long nor so much curved, rather stronger legs, and longer toes, three before, and one behind. The COMMON S., or CHIMNEY S. (*Hirundo rustica*), exhibits a character

Swallows:
1, Common or Chimney Swallow (*Hirundo rustica*); 2, Sand Martin (*H. riparia*); House Martin (*H. bicolor*).

common to many other species, in the very long and deeply-forked tail, the two lateral feathers of which far exceed the others in length. The plumage is very beautiful, the upper parts and a band across the breast glossy bluish black, the forehead and throat chestnut, the lower parts white, and a patch of white on the inner web of each of the tail-feathers except the two middle ones. The whole length of the bird is about 8½ inches, of which the outer tail-feathers make 5 inches. The nest is made of mud or clay, formed into little pellets and stuck together, along with straw and bents, and lined with feathers. It is open and cup-shaped, and is generally placed in a situation where it is sheltered from wind and rain, as a few feet down an unused chimney, under the roof of an open shed, or in any unoccupied building to which access can be obtained. Two broods are produced in a year. The migration of this and other British species of S., now recognised by all naturalists as an unquestionable fact, was formerly the subject of much dispute, and swallows were supposed by many to become torpid in winter, although it was difficult to imagine that if so they should not frequently be found in that state. The geographical range of this species extends over great part of Europe, Asia, and Africa.—The WINDOW S., or HOUSE-MARTIN (*H. bicolor*, or *Chelidon urbica*), is another very common British species, glossy black above, white below, and on the rump; the feet covered with short downy white feathers, which is not the case in the Chimney S.; the tail long, but its outer feathers not remarkably so. The nest is built of mud or clay, like that of the Chimney S., but is hemispherical, with the entrance on the side, and is attached to a rock, or, very frequently, to the wall of a house, under the eaves or in the upper angle of a window, to the annoyance of housekeepers who prefer the cleanness of their windows to the lively twitter of the birds, and the opportunity of watching their process of nest-building and their care of their young. House-martins congregate in great numbers, as chimney swallows also do before their autumnal migration, and disappear all at once. The house-martin is among the birds of Lapland and Iceland. The only other common British species of S. is the SAND-MARTIN (*H. riparia*), smaller than either of the preceding, the toes naked, the tail moderately forked, the plumage brown on the upper parts and across the breast, the under parts white. It makes its nest in sandy river-banks, the sides of sand-pits and other such situations, excavating a gallery of 18 inches or 2 feet, sometimes 3, or even 5 feet in length, and more or less tortuous, in the extremity of which some soft material is placed for the reception of the eggs. This wonderful excavation is accomplished entirely by the bill of the bird. The floor slopes a little upwards from the entrance, so that the lodgment of rain is prevented. The sand-martin is more local than the other British swallows; but it is distributed over most parts of Europe, Asia, Africa, and North America.—The PURPLE S., or PURPLE MARTIN (*H. purpurea*), is a North American species, which has in a few instances been known to visit the British islands. The general colour, both of the upper and under parts, is shining purplish blue; the wings and tail black. It abounds in North America, and is a universal favourite in the northern parts, being hailed as the harbinger of spring, and frequenting even the streets of towns. It is a very general practice to place boxes near houses for the martins to make their nests in, which are very inartificial, consisting merely of dried grass, leaves, moss, feathers, and the like. Boxes nailed to trees are also readily occupied by the RUFOUS-BELLIED S. (*H. horreorum*), another North American species. But this species, which very nearly resembles the Chimney S. of Britain, makes a nest of mud and fine hay, in the form of the half of an inverted cone, with an extension at the top, for one of the parent birds to sit in occasionally. The REPUBLICAN S., or CLIFF S. (*H. lunifrons*), of North America, makes a nest of mud, in form somewhat like a Florence flask, which it attaches to a rock or to the wall of a house. Hundreds sometimes build their nests in close proximity. The FAIRY MARTIN (*H. Ariel*), a small Australian species, also builds a flask-shaped nest, with the mouth below, attaching it to a rock, or to the wall of a house, and numerous nests are often built close together.—Some of the swallows of tropical countries are much smaller than any of the European species.—The East Indian swallows, which make the Edible Nests (q. v.), belong to the section of the family to which the name Swift is given.

SWALLOWING, THE ACT OF, is accomplished by a set of associated movements which have been divided by physiologists into three stages. In the first stage, the food having been previously duly reduced to a pulp by trituration and insalivation, is

carried back by the contraction of various muscles until it has passed the anterior palatine arch. See PALATE. So far, the movements are purely voluntary. The second stage now commences, during which the entrance of food into the nasal cavities and larynx is most carefully guarded against by certain reflex (involuntary) actions, which have been only clearly recognised since the introduction of the use of the laryngoscope during the last few years. The tongue is carried further backwards, the larynx rises so as to be covered by the epiglottis, which is depressed, and lies horizontally, so that its upper border touches the posterior wall of the pharynx. Coincident with these movements, the sides of the posterior palatine arch contract by muscular action, and approach each other like a pair of curtains, so as almost to close the passages from the fauces into the posterior nostrils; the closure being completed by the uvula. A sort of inclined plane is thus formed, and the morsel slips downwards and backwards into the pharynx, which is raised to receive it. Very little, if any, voluntary action is here exerted. The third stage—the propulsion of the food down the œsophagus—then commences; and this process is effected in the upper part by means of the constrictor muscles of the pharynx, and in the lower, by the muscular coat of the œsophagus itself. At the point where the latter enters the stomach, there is a sort of sphincter muscle, which is usually closed, but which opens when sufficient pressure is made on it by accumulated food, closing again when this has passed.—See Carpenter's *Principles of Human Physiology*, 6th ed. p. 61.

SWALLOW-WORT. See ASCLEPIAS.

SWAMMERDAM, JAN. See SUPP. in Vol. X.

SWAN (*Cygnus*), a genus of birds of the Duck (q. v.) family (*Anatidæ*), constituting a very distinct section of the family. They have a bill about as long as the head, of equal breadth throughout, higher than wide at the base, with a soft cere, the nostrils placed about the middle; the neck very long, arched, and with 23 vertebræ; the front toes fully webbed, the hind toe without membrane; the keel of the breast-bone very large; the intestines very long, and with very long cæca. They feed chiefly on vegetable substances, as the seeds and roots of aquatic plants, but also on fish-spawn, of which they are great destroyers. They are the largest of the *Anatidæ*. They have a hissing note like geese, which they emit when offended, and strike with their wings in attack or defence. The common notion, that a stroke of a swan's wing is sufficient to break a man's leg, is exaggerated. The COMMON S., MUTE S., or TAME S. (*C. olor*), is about 5 feet in entire length, and weighs about 30 lbs. It is known to live for at least 50 years. The male is larger than the female. The adults of both sexes are pure white, with a reddish bill; the young (cygnets) have a dark bluish-gray plumage, and lead-coloured bill. The bill is surmounted by a black knob at the base of the upper mandible, and has a black nail at its tip. In its wild state, this species is found in the eastern parts of Europe and in Asia; in a half-domesticated state it has long been a common ornament of ponds, lakes, and rivers in all parts of Europe. It is an extremely beautiful bird, when seen swimming, with wings partially elevated, as if to catch the wind, and finely curving neck. The ancients called the S. the Bird of Apollo or of Orpheus, and ascribed to it remarkable musical powers, which it was supposed to exercise particularly when its death approached. It has, in reality, a soft low voice, plaintive and with little variety, which is to be heard chiefly when it is moving about with its young. The nest of the S. is a large mass of reeds and rushes near the edge of the water, an islet being generally preferred. From 5 to 7 large eggs are laid, of a dull greenish-white colour. The female S. sometimes swims about with the unfledged young on her back; and the young continue with their parents till the next spring. The S. is now seldom used in Britain as an article of food, but in former times it was served up at every great feast, and old books are very particular in directions how to roast it and to prepare proper gravy.—The POLISH S. (*C. immutabilis*), of which flocks have occasionally been seen in Britain in winter, differs from the Common S. in its orange-coloured bill, in the smaller tubercle at its base, and in the shape and position of the nostrils. The young are also white, like the adults. It belongs chiefly to the north-eastern parts of Europe. Many naturalists regard it as the true wild state of the Common Swan.—The WHISTLING S., ELK S., or HOOPER (*C. ferus*),

Wild Swan, or Hooper (*Cygnus ferus*), and Black Swan (*C. atratus*).

abounds in the northern parts of Europe and Asia. Flocks frequently visit Britain in severe winters, and their migrations extend as far south as Barbary. A few breed in the Orkney Islands, but the greater number in more northern regions. The size is about equal to that of the Common S., and the colour is similar, but the bill is more slender, is destitute of knob, and is black at the tip, and yellow at the base. This bird is frequently brought to the London market. The names Hooper and Whistling S. are derived from the voice. The anatomical differences between this species and the Common S. are more considerable than the external, particularly in the double keel of the breast-bone forming a cavity which receives a long curvature of the windpipe.—BEWICK'S S. (*C. Bewickii*), another native of northern Europe, is more rare in Britain, but flocks are sometimes seen. It is about one-third smaller than the Whistling Swan.—The AMERICAN S. (*C. Americanus*) nearly resembles Bewick's Swan. It breeds in the northern parts of North America, and its winter migrations extend only to North Carolina.—The TRUMPETER S. (*C. buccinator*) is another American species, breeding chiefly within the Arctic Circle, but of which large flocks may be seen in winter as far south as Texas. It is rather smaller than the Common Swan.—The ancients spoke of a black S. proverbially as a thing of which the existence was not to be supposed, but Australia produces a BLACK S. (*C. atratus*), rather smaller than the Common S., the plumage deep black, except the primaries of the wings, which are white. The bill

is blood-red. It has been introduced into Britain, and breeds freely. It is very abundant in some parts of Australia.—The BLACK-NECKED S. (*C. nigricollis*) is a South American species, as is the DUCK-BILLED S. (*C. anatoides*), the smallest of all the species, white, with black-tipped primaries, common about the Strait of Magellan. It is a curious circumstance that the black colour appears more or less in all the species of the southern hemisphere, and in them alone, except in the approach to it made in cygnets.

Swans, according to the law of England, are birds-royal. When they are found in a partially wild state, on the sea and navigable rivers, they are presumed to belong to the crown, and this is one of the prerogatives of the crown, though it may be delegated to a subject. The royal birds generally have a mark on them, and the king's swan-herd once was an important person. A subject is not entitled to have a swan-mark unless he has a qualification of land, and has a grant from the crown, or prescriptive use. But any person may have swans in his grounds in a tame state, and then he has a property in them. Whoever steals or destroys swans' eggs, forfeits 5*s.* for every egg, and whoever steals a marked swan of the crown, or a tame swan, commits felony. In Scotland, there is some trace of the bird having been once treated with royal honours, but latterly they have been in the category of other tame birds.

SWA'NSEA (Welsh, *Abertawy*), a market-town, municipal and parliamentary borough and seaport of the county of Glamorgan, South Wales, stands on the right bank and at the mouth of the Tawe, 60 miles west-north-west of Bristol. The harbour is formed by means of piers of masonry, projecting from either side of the mouth of the Tawe into Swansea Bay, a wide inlet of the Bristol Channel. The vast resources of the coal-field in the midst of which the town is situated, began to be explored and turned to commercial account about the year 1830; and since that time the progress of S. has been so rapid, that it is now (1875) the most important town in South Wales. The houses and public edifices and institutions are of recent erection. A new and costly market-place was opened in 1830, and a new fish-market in 1847. Smelting and refining copper is the staple trade of the town, and the chief source of its prosperity. The coal obtained in the vicinity is peculiarly adapted for smelting purposes, and great quantities of ore are brought hither to be smelted, not only from the copper-mines of Britain, but from Cuba and the west coast of South America. In the immediate vicinity of the town, there are smelting-works, in which about 185,800 tons of copper, copper ores, silver ores, and zinc ores (equal in value to about £4,000,000) are smelted annually. In 1859, a large floating dock, 13 acres in extent, was opened by the side of the harbour. Its north side is lined with warehouses and staiths for the shipment of coals, which are brought to the wharfs by the South Wales, the Vale of Neath, the Swansea Valley, and the Swansea and Llanelly Railways. Patent fuel, composed of a mixture of culm and tar, and compressed into the shape of bricks, is an important article of manufacture and trade. There are extensive potteries and tin, silver, and china works, breweries, rope-walks, and tanneries. Of the whole amount of copper manufactured in Great Britain, seven-eighths are smelted at S. and in its immediate vicinity. In 1867, 14,559 vessels, of 1,812,911 tons, entered and cleared the port. There are abundant means of communication landward by canals and railways. Pop. (1851) of municipal and parliamentary limits, 31,461; (1861) 41,606; (1881) of municipal borough, 63,739; of parliamentary district of boroughs, 105,949. Of the old castle of S., the ruined remains are used as a military store. S. unites with several other boroughs in sending a member to the House of Commons.

SWARGA is the paradise of the Hindu god Indra (q. v.). It is the residence of some of the inferior gods and deified mortals, who there rest in the shade of the five wonderful trees—*Mandâra*, *Pârijâta*, *Santâna*, *Kalpavr'iksha*, and *Harichandana;* drink *Amr'ita*, or the beverage of immortality; and enjoy the music of the *Gandharvas*, and the dancing of the heavenly nymphs, the *Apsarasas*.

SWARMING, a peculiar mode of reproduction which has been observed in some of the *Confervaceæ*, *Desmideæ*, &c. The granules which form the green matter in the plant, or in one of its joints, become detached from each other, and move about in the cell with great rapidity. The external membrane swells in one point, and finally bursts there, when the granules escape into the surrounding water to become new plants. At first, they issue in great numbers, but those which remain last, move about within their cell for a long time before they find the way out. Their motion is supposed to be due to cilia. After escaping, the most of them finally become grouped together in little masses on some substance, before beginning to vegetate.

SWATOW, China. See SUPPLEMENT in Vol. X.

SWE'ABORG, or SVE'ABORG, a great Russian fortress in the principality of Finland, and government of Viborg, sometimes called 'the Gibraltar of the North,' protects the harbour and town of Helsingfors, from which it is only 3 miles distant. The fortifications extend over seven islands, the *Nylandischen Skären*, but the grand central point is the island of Wargöe. The islands are connected with each other by means of bridges, and between two of them lies the single narrow entrance to the harbour, which can hold from 70 to 80 ships of the line. S. has a civic population of about 3000, the greater part of whom are manual labourers, ship-carpenters, and traders, and a garrison of some 5000 men (including women and children). During the Crimean war, the Anglo-French fleet in the Baltic made a reconnaissance of the place, and bombarded it for two days (9th and 10th August 1855), but found the defences too formidable to be reduced by the means at their disposal.

SWEARING, PROFANE, according to the law of England, is an offence for which the party may be convicted by a justice of the peace according to a scale of penalties. A day labourer, common soldier, sailor, or seaman forfeits 1*s.* per oath; every other person under the degree of a gentleman, 2*s.*; and every person above the degree of a gentleman, 5*s.*—for a second offence, double these sums; for a third, treble, &c. If the cursing takes place in presence of a justice of the peace, the latter may convict the swearer then and there, without further process or evidence; and in all cases a constable may apprehend a profane swearer, and carry him before a justice. On a recent occasion, a man swore a volley of oaths, twenty times repeating the oath, and the justices fined him 2*s.* for each repetition, making in all £2, and this was held a proper conviction. The justices of the peace in Scotland have a similar jurisdiction intrusted to them, to convict of profane swearing, and fine according to the rank of the party.

SWEAT (A.-S. *swat;* Sansc. *swai las;* Lat. *sudor;* Gr. *hydor*, moisture; Lat. *ud(us)* = wet), or Perspiration. The nature, composition, and uses of this fluid in the normal state have been

sufficiently noticed in the article SKIN. It may be additionally remarked, in connection with the physiology of sweat, that the composition of this fluid varies materially according to the part of the body from which it is secreted. Thus Funk found the sweat of the feet was richer in fixed salts than that of the arm, in the ratio of 5 to 3; and Schotten found a considerable preponderance of potassium in the former. In the negro, Dr Copland and other observers have found that both the gaseous exhalations from the skin, and the solid matters contained in the sweat, were much greater than in the white races. It has been shewn in the article SKIN that the sweat-glands, like the lungs and kidneys, act as depurating organs, and separate and carry off effete matters from the blood. This eliminating action of the skin is modified in various diseases; in some cases being diminished, as in the early stage of fevers, in inflammations before suppuration commences, in scurvy, diabetes, sun-stroke, &c., while it is more or less increased in the sweating stage of ague, in acute rheumatism, in Asiatic cholera, in certain adynamic fevers, in the advanced stages of pulmonary consumption, in the formation of matter in internal parts, &c. The sweat is naturally acid in health, but in prolonged sweating the secretion becomes neutral, and finally alkaline. Little is known with certainty regarding the colouring matters of sweat. In cases of jaundice, the sweat sometimes communicates a yellow tinge to the body-linen; and instances of blue, red, and bloody sweat are on record. Cases of sweat of these colours are recorded in Simon's *Animal Chemistry* (Syd. Soc. Trans.), (Lond. 1845), vol. ii., p. 110. Cases of unilateral sweating, stopping abruptly at the middle line, have been occasionally noticed, especially in aneurism of the aorta.—See Gairdner's *Clinical Medicine*, p. 557. Dr Druitt has recently pointed out the use of hot water as a remedy for profuse perspiration. He has found it serviceable in (1) oversweating in good health and hot weather; (2) undue sweating in special parts of the body, as the hands, feet, or armpits; (3) true hectic; and (4) ordinary night sweats in phthisis not preceded by hectic symptoms. To be of any service, the water must be applied at as great a heat as the patient can possibly bear (see his paper on this subject in the *Medical Times* for March 4, 1865). For a very interesting and learned discussion on our Saviour's bloody sweat during his Passion, the reader may consult Stroud *On the Physical Cause of the Death of Christ*, and Trusen's chapter *Von dem Blutschweisse Christi* in his *Darstellung der Biblischen Krankheiten*, 1843.

SWEATING SICKNESS, THE, is the term given to an extremely fatal epidemical disorder, which ravaged Europe, and especially England, in the 15th and 16th centuries. It derives its name 'because it did most stand in sweating from the beginning vntil the endyng,' and 'because it first beganne in Englande, it was named in other countries the Englishe sweat.'—*The Boke of Jhon Caius against the Sweatyng Sicknes.* It first appeared in August, 1485, in the army of Henry VII., shortly after his arrival at Milford in South Wales from France, and in a few weeks it spread to the metropolis. It was a violent inflammatory fever, which, after a short rigor, prostrated the powers as with a blow; and amidst painful oppression at the stomach, headache, and lethargic stupor, suffused the whole body with a fœtid perspiration. All this took place in the course of a few hours, and the crisis was always over within the space of a day and night. The internal heat which the patient suffered was intolerble, yet every refrigerant was certain death. *Scarce one amongst a hundred* that sickened did escape with life.'—Holinshed, vol. iii., p. 482. Two lord mayors of London and six aldermen died within one week; and the disease for the most part seized as its victims robust and vigorous men. It lasted in London from the 21st (some authorities say the middle) of September to the end of October, during which short period 'many thousands' died from it. The physicians could do little or nothing to combat the disease, which at length was swept away from England by (as many supposed), a violent tempest on New-Year's Day. The disease did not reappear till the summer of 1506, when it broke out in London, but does not seem to have occasioned any great mortality. In July 1517, it again broke out in London in a most virulent form; it being so rapid in its course that it carried off those who were attacked in two or three hours. Amongst the lower classes, the deaths were innumerable, and the ranks of the higher classes were thinned. In many towns a third, or even a half of the inhabitants were swept away. On this occasion, the epidemic lasted about six months. In May 1528—the year in which the French army before Naples was destroyed by pestilence, and in which the putrid fever known as *Trousse-galant* decimated the youth in France—the sweating sickness again broke out in the metropolis, spread rapidly over the whole kingdom, 'and fourteen months later, brought a scene of horror upon all the nations of Northern Europe, scarcely equalled in any other epidemic.'—Hecker's *Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 238. How many lives were lost in this epidemic, which has been called by some historians *the great mortality*, is unknown; but the mere fact that the king (Henry VIII., who, whatever his faults, was never accused of cowardice) left London, and endeavoured to avoid the disease by continually travelling, shews the general feeling of alarm that existed. In the following summer (July 25, 1529), having apparently died out in England, it appeared in Germany, first at Hamburg, where it is recorded that 8000 persons died of it, and shortly after at Lubeck, Stettin, Augsburg, Cologne, Strasburg, Hanover, &c. In September, it broke out in the Netherlands, Denmark, Sweden, and Norway, whence it penetrated into Lithuania, Poland, and Livonia. By January of the following year, after an existence of three months, it had entirely disappeared from all these countries. For three-and-twenty years the sweating sickness totally disappeared, when for the last time (April 15, 1551) it burst forth in Shrewsbury. The banks of the Severn seemed to be the focus of the malady which was carried from place to place by poisonous clouds of mist. There died within a few days 960 of the inhabitants of Shrewsbury, the greater part of them robust men and heads of families. The disease spread rapidly over the whole of England, but seems to have disappeared by the end of September. The deaths were so numerous, that one historian (Stow) states that the disorder caused a *depopulation* of the kingdom. The very remarkable observation was made in this year, that the sweating sickness uniformly spared foreigners in England, and on the other hand, followed the English into foreign countries. The immoderate use of beer amongst the English was considered by many as the principal reason why the sweating sickness was confined to them. 'By the autumn of 1551,' says Hecker, 'the sweating sickness had vanished from the earth; it has never since appeared as it did then and at earlier periods; and it is not to be supposed that it will ever again break forth as a great epidemic in the same form, and limited to a four-and-twenty hours' course; for it is manifest that the mode of living of the people had a great

share in its origin, and this will never again be the same as in those days. — *Epidemics of the Middle Ages* (Syd. Soc. Trans.), p. 306.

SWE′DEN (*Sverige*), the eastern portion of the Scandinavian peninsula, constitutes with Norway (q. v.) one joint kingdom. It is situated in 55° 15′ - 69° N. lat., and 11°—24° E. long., and is bounded on the N. and W. by Norway; on the extreme S.W. and S. by the Cattegat, which separates it from Denmark; on the S.E. and E., as far as 66° N. lat., by the Baltic; and from thence to the extreme N. by Russia. The area is given at 170,629 sq. m.; and the pop. was, in 1880, 4,565,668. Its length is upwards of 900 miles, and its greatest width from 150 to 200 miles. Unlike Norway, S. possesses few high mountains, but contains numerous lakes of large dimensions. The coast skirting the Baltic, and the adjoining islands, are for the most part low and sandy, although in some parts, as in the vicinity of the outlet of Lake Maelar into the sea (in about 58° N. lat.), the shores are rocky; and on the south and west coasts, it is only at isolated spots, as near Gottenborg, that the generally low, sandy, or alluvial lands are replaced by more rocky formations.

In the northern parts, the land rises gradually from the Gulf of Bothnia to the Kiölen Mountains, which form the boundary between S. and Norway. South of 62° N. lat., the slope is directed southward, attaining its lowest level in the vicinity of the three great lakes of Wener, Maelar, and Hielmar, which nearly intersect the country from east to west; and south of these great inland waters, the surface is in general level, though ranges of high ground and detached hills occur.

The mountainous region of S. may, moreover, be considered to be divided into three distinct parts, viz., the northern or alpine part, the central or lake district, and the southern or mining district. The first of these comprises the Kiölen range, the most elevated parts of which are above the line of perpetual snow. The rivers do not admit of navigation, and the inhabitants of this district, whose means of living are principally derived from the rearing of cattle, can have little intercourse with the natives of other parts of the country. The central portion of the mountain-district comprises the great tablelands of Jemtland, and the valleys of Herjedal and Ljungan, which admit of higher cultivation, while the banks of the numerous small lakes and rivers afford good pasturages for cattle and sheep, and the slopes and summits of the hills yield timber of good quality. In the southern part of the mountain-tract lies the region of mines, which extends from Norway to the Gulf of Bothnia, and is bounded to the north by Lake Siljan, and to the south by Lake Wener. This district includes the famous iron mines of Danemora and the copper-works of Fahlun, besides many others of great importance; and although not generally fertile, the soil is carefully cultivated for the supply of the mining population, which, during the last few years, has been considerably augmented.

To the south of this region of mines lies the only level and fertile tract, in which wheat can at all times be advantageously and extensively cultivated. This agricultural district, which includes some of the larger lakes, consists of level meadow and arable lands, and extensive table-lands, traversed by wooded ridges, and is the only part of S. which can be said to be free from the huge masses of erratic rocks, chiefly gneiss, which occur in such large numbers over almost the whole of the Scandinavian peninsula. The coast of this central portion of S. is fringed with long lines of disjointed cliffs or islands, separated from one another by numerous narrow passages, whose intricate windings render access to the shore tedious and difficult. The peninsular extremity of S., which lies between the Cattegat and the Baltic, includes some of the most fruitful and picturesque districts of the kingdom.

The lakes of S., which are very numerous, have been computed to cover nearly ⅛th of the entire area of the country. The largest of these, Lake Wener (q. v.), is fed by the river Klar, and emptied into the Cattegat by the Göta. The Göta, which is noted for its picturesque rapids, and the falls known as the Ränum and Trolhätten, has, by means of the admirable system of canals and locks designed by the English engineer, Telford, been made conducive to the line of internal navigation which now connects the Cattegat with the Baltic. Lake Wetter (q. v.) is included in this great scheme of inland navigation, but the heavy gales to which both this lake and Lake Wener are subject, often render their navigation difficult and dangerous. The Maelar (q. v.) Lake extends along a length of 70 miles, and continues this system of water communication eastward to the shores of the Baltic.

The rivers of S. have generally so short and rapid a course that it is only by art that they can be rendered navigable. The largest of these is the Angerman River or Elv, formed by the junction of four parallel streams, which, after passing through some of the large alpine lakes, empties itself into the Gulf of Bothnia, which also receives the Ljungan, Indal, Ljusne, Dal, Umea, Pitea, Lulea, Tornea, &c. The course of these rivers is generally directed from north-west to south-east, and many of them being swelled by the affluence of numerous mountain streams, merge into tarns, or expand into extensive alpine lakes; and although of little practical utility for direct navigation, they afford the greatest facilities for internal navigation, and for conducting manufacturing operations by water-power.

The differences of climate in S. are necessarily very great, considering that its most northern parts are more than 2° within the polar circle, and its southern extremity 11° south of it, besides being so nearly surrounded by seas and lakes as to have nearly the conditions of an insular position. Great extremes of temperature are common in different parts of S.: thus, while Stockholm has a mean annual temperature of 42°·2 Fahr., and Gottenborg 46°·3, the summer temperature of the former is 60°·4 Fahr., and that of the latter 62°·13; and the winter temperature of the former only 25°·8, and that of the latter 31°·5 Fahr.

The heat of the summer, which is scarcely separated from the cold of the winter by either spring or autumn in the extreme northern districts, enables the inhabitants to cultivate barley, which is reaped within two months of the time of its sowing, although even the hardier cereals, as oats and rye, will not ripen above the parallel of 66° N. lat.. Indeed, the climate of S. generally is unfavourable to the growth of grain, the annual yield of which frequently falls short of the wants of the population. The principal articles of cultivation are, in addition to the various cereals, potatoes, hemp, flax, tobacco, and hops, which are generally grown in sufficient quantities for home consumption. The pine, fir, and beech, met with even in the most northern parts of the country, at the respective elevations of 3000, 2500, and 1800 feet above the level of the sea, are of great importance, not only for the timber, tar, and pitch which they yield, but also on account of their supplying charcoal and firewood, which, in the absence of coal, constitute the principal kinds of fuel. The forests are of great extent, covering more than a fourth part of the surface of S.,

although the greater portion of the land lying north of 64° is destitute of trees, as are also the alpine slopes at elevations of 3000 feet above the sea, where stunted bushes, berries, dwarf-plants, and lichens are the only forms of vegetation to be met with. The common fruit-trees, as cherries, apples, and pears, grow as far north as 60°, but the fruit seldom comes to great perfection except in the southern provinces; cranberries and other berries abound, however, in all parts of the country. Bears and beavers, which were formerly often met with, are becoming scarce; but wolves, lynxes, foxes, martens, squirrels, eagles, &c., are still common; while the elk and deer are found in some of the forests, which abound in hares, woodcocks, black-cock, and various other kinds of small game; and Lemmings (q. v.) occasionally descend from the mountains in large numbers, and lay waste the low country. The lakes yield a great abundance of fish, 88 different kinds of sea and fresh water fish being brought to market.

The mineral products of S., which are extremely rich, include some gold and silver (which, however, do not pay the cost of working), copper in abundance, iron of the finest quality in almost every province, alum, vitriol, marble, sulphur, lead, nickel, zinc, and some coal of very inferior quality.

Next to agriculture, mining constitutes the most important branch of national industry, and in some provinces is the principal employment. The Danemora mines, in Upsala Laen, yield a metal which is capable of being converted into the finest steel. S. had, in 1869, 2195 factories, employing 26,042 labourers. The value of the manufactures amounts yearly to 82,321,000 rixdaler. Iron is mined from 461 mines, 340,000 tons of pig iron are made at 200 furnaces, and 211,000 tons of iron rolled at 375 rolling works.

Shipbuilding forms an extensive branch of local industry. The merchant marine numbered, in 1872, 3878 vessels, of 425,973 tons, of which 498 were steamships, of 16,292 horse-power. The number of vessels employed in internal navigation in 1872 was 1783, with a tonnage of 334,592. Of railways 2090 were completed in 1874, and 1292 miles were in course of construction.

The chief articles of export are iron and timber, copper, cobalt, alum, hemp, oil, birch-bark, hides, furs, paper, tobacco, home-spun linens, pitch and tar, &c. The Baltic lands, Great Britain, France, Portugal, and the Brazils take the greater part of these articles. The imports include yarn, wool, cotton, leather, coals, salt, machines, manure, and the ordinary colonial produce. The value of the imports in 1872 was 216,366,000 rixdaler, or about $54,091,500, and that of the exports 199,815,000 rixdaler, or about $49,953,750.

In 1858 the decimal system was introduced into S., when the standard foot, which was retained, was divided into ten inches of ten lines, and the old standard pound made the basis of the hundredweight of 100 pounds. The rixdaler rixmynt (=100 oere, or about 1*s.* 2*d.*) has, in accordance with the decree of 1855, been made to supersede the old rixdaler banco of 150 oere.

The total estimated receipts and expenses, according to the budget for the year 1875, amount to 99,249,939 rixdaler = £5,458,746, or $26,529,500, of which the ordinary receipts are 25,135,000 rixdaler; ordinary expenses, 51,836,800 rixdaler; extraordinary receipts, 39,640,000; expenses, 28,447,108; income from loans, &c., 34,474,939; interest on public debt, and other expenses, 18,966,031 rixdaler. During the 6 years from 1865 to the end of 1870, the diet voted 100 million rixdaler for the construction of railroads. Until the year 1857, S. had no external foreign debt; but at the close of 1873 the sum total of the national debt was 89,840,000 rixdaler, or about $22,460,000.

S. is divided into three great provinces—viz., Norrland, the largest and most northerly; Sweden Proper, or Svea-Rike, in the centre; and Gotland, or Gotha-Rike, to the south. These divisions, of which the last two derive their names from the respective nations or tribes by whom they were originally settled, are now merely nominal, and have ceased to indicate any municipal districts since the whole of S. was divided into Laens, or administrative circles, of which there are 25, which are under the jurisdiction of special magistrates, and are further subdivided into bailiwicks, hundreds, and parishes.

With the exception of Stockholm (q. v.), the capital, and Gottenborg (q. v.), there are only two towns with more than 20,000 inhabitants, and seven other towns with populations of more than 8000.

The only Swedish colony is the small island of St Bartholomew, in the group of the Lesser Antilles, which is only about 20 sq. m., with 2800 inhabitants.

The Swedish army, which in 1873 consisted of 150,773 men, has a special and peculiar organisation, as it consists principally of cantoned or quartered soldiers, who are maintained at the cost, and on the property, of the landed proprietors: each estate being mulcted according to its value or extent to maintain one or more men, and provide them with special dwellings, a certain portion of land, and a fixed rate of payment. In return, these reserve soldiers, who are for the most part married men, serve the proprietor as field-labourers in times of peace, except during the four weeks of each year in which they are called out for drill. In case of war they can be sent, with the companies in which they are enrolled, into active service, and they are then paid by the crown. The rest of the army is made up of volunteers, who serve for six years, every Swede between the age of 20 and 25 years being moreover bound to serve in the *bevaring* or National Guard. In addition to these corps, companies of volunteer free-shooters were created in 1861 for the general defence of the country, and placed under the command of officers appointed by the crown. The fleet consisted, in 1874, of 133 vessels of war, including 27 steamers and 96 sailing-vessels, carrying, in all, 455 cannons and 7743 men. In time of war a coasting merchant-fleet of 3200 vessels can be called into requisition, together with a reserve of 28,000 men. The principal fortresses are Carlsten, Gottenborg, Carlskrona, and Fredericksborg, 20 miles east of Stockholm. The military and other orders are the Seraphim, the Sword, the Northern Star, and the order of Vasa. The order of Charles XIII. embraces the highest rank of freemasons in Sweden.

S. is a hereditary and constitutional monarchy, based on the fundamental law of 1809, by which it was decreed that the succession should be in the male line; that the sovereign should profess the Lutheran faith; and that he should be assisted in the administration by a council of 10, consisting of 3 privy councillors, besides the ministers of justice, war, the marine, finance, religion, foreign affairs, and internal affairs. The diet, according to the amended regulations of Dec. 8, 1865, assembles every year, and votes the budget for the same period. It is composed of two chambers or estates, both elected by the people, but representing different interests. The first chamber, or upper house, consists of 127 members, or one deputy for over 30,000 people, chosen for 9 years, and selected from those who possess either landed property of taxed value of 80,000 rixdaler, or annual income of 4000 rixdaler. The second chamber, or lower house, consists of 188 members, elected for the towns and rural districts, 1 for every 10,000 of the former, and 1 for every 40,000 of the latter. The electors must be aged 21 years, and possess a small property or income. Committees of the two houses maintain a

watch over all constitutional questions, and have the power of calling upon ministers and other members of the government for explanations, and a constitutional committee has the power to indict the ministers and chief servants of the crown for mal-administration. The king has an absolute veto against any decrees of the diet, and possesses legislative power in matters of provincial administration and police.

The predominant form of religion in S. is the Lutheran, and the affairs of the church are administered by 1 archbishop (of Upsala) and 11 bishops, whose collective dioceses include about 2500 parishes, with about 3500 pastors. Although toleration is extended to all sects, none but Lutherans can hold the offices of the state, or receive employment in the public service; while the adoption of any other form of faith, by a member of the established Lutheran church, is followed by the loss of various burgher rights. Jews, Catholics, and members of other denominations number only a few thousands, and the only form of dissent that has acquired any important dimensions in S., in recent days, is that of the so-called Readers, who profess to have revived the primitive form of Lutheranism, and restrict themselves to the reading and individual interpretation of the Scriptures.

Education is universally diffused among the Swedes. Public instruction is compulsory for all children, and the cost is defrayed by the nation through national and ambulatory schools, which are well organised; many are trained at home in consequence of the national habit which prevails among the peasant and agricultural classes, of parents employing themselves, in the long winter nights, in teaching their children. The instruction of the burgher and higher classes is obtained at the universities of Upsala and Sund (the former of which was founded, in 1476, by Sten Sture, and the latter, in 1666, by Charles XI.), and at the numerous military, polytechnic, agricultural, and other special schools in Stockholm and Gottenborg, and other principal towns of Sweden.

History.—The legendary history of S. forms part of Scandinavian history. When we first hear of it, the country was inhabited by numerous tribes, kindred in origin, but politically separate. Two principal groups, however, are recognisable—*Goths* in the south, and *Swedes* in the north. These possessed in common a national sanctuary, the temple at Upsala, which laid the basis of a later unification, for gradually the royal chieftains of Upsala extirpated the inferior princes, the Härads and the Fylkis. Ingiald Hrada, the last ruler of the old royal family of the Ynglinger, who drew their origin from Niord, sought to establish a single government in Sweden, and perished in the attempt. To the Ynglinger followed in Upland the dynasty of the *Skioldunger*, which claimed to be descended from Skiold, son of Odin. Erich Edmundson, who belonged to this dynasty, is said to have acquired the sovereignty of the whole of Sweden about the end of the 9th century. The dawn of Swedish history (properly so called) now begins, and we find the Swedes constantly at war with their neighbours of Norway and Denmark, and busily engaged in piratical enterprises against the eastern shores of the Baltic. See NORMANS and RUSSIA. Efforts to introduce Christianity (see ANSGAR) were made as early as 829 A.D., but it was not till 1000 A.D. that Olaf Schooszkönig was baptised, nor did the struggle between heathenism and the new religion cease till the burning of the temple of Upsala, in the reign of Ingiald (1080—1112). In 1155, Eric, surnamed the Saint, gave a powerful impetus to the diffusion of Christian doctrines, by building churches and founding monasteries. He undertook a crusade against the pagan Finns, and having compelled them to submit to baptism, and established Swedish settlements among them, he laid the foundation of the closer union of Finland with Sweden. Eric's defeat and murder, in 1161, by the ambitious young Danish prince, Magnus Henriksen, who had made an unprovoked attack upon the Swedish king, was the beginning of a long series of troubles, and during the following 200 years, one short and stormy reign was brought to a violent end by murder or civil war, only to be succeeded by another equally short and disturbed; until, at length, the throne was offered by the Swedish nobles to Margaret, Queen of Denmark and Norway, who, having gladly availed herself of the opportunity thus opened to her of uniting the three Scandinavian crowns into one, threw an army into S.; defeated the Swedish king, Albert of Mecklenburg, who, on the deposition of his maternal uncle, Magnus, had been called to the vacant throne; and by the union of Calmar, in 1397, brought S. under one joint sceptre with Denmark and Norway. In 1523, S. emancipated itself from the union with Denmark, which, during the reigns of Hans and his son Christian II. (see DENMARK), had become hateful to the Swedes, and rewarded its deliverer, the young Gustaf Vasa (q. v.), by electing him king, and declaring its independence of Denmark. Gustaf Vasa found an empty treasury, a kingdom exhausted by war, a haughty nobility and clergy (who arrogated the right of electing the sovereign, and who claimed exemption from all imposts), and a people overburdened with taxation and bad government, and divided in regard to religion; yet on his death, in 1560, he left to his successor a hereditary and well-organised kingdom (in which the power of the nobles had been circumscribed, and that of the clergy broken, by the abrogation of Catholicism, and the firm establishment of the Reformed Church under the jurisdiction of the state), a full exchequer, a standing army, and a well-appointed navy. Trade, manufactures, arts, learning, and science, owed their advancement in S. to this patriotic king.

The colossal labours of the great Vasa in raising a semi-barbarous state to an honourable place among the civilised monarchies of Europe, were rendered almost useless by the crimes and misfortunes of his son and successor, Eric XIV., whose high intellectual powers were clouded by a wayward and revengeful nature, leading him finally to insanity. His cruelties and excesses led to his deposition in 1568, when his younger brother John ascended the throne, which he occupied for nearly a quarter of a century, dying in 1592, after a stormy reign, stained by the cruel murder of his unfortunate brother Eric, and distracted by the internal dissensions arising from his attempts to force Catholicism on the people, and the disastrous wars with the Danes, Poles, and Russians. John's son and successor, Sigismund, who had been elected king of Poland through the influence of the relatives of his Polish mother, after a short and stormy reign of eight years, which were spent in attempting to restore Catholicism in S., was compelled by the diet to resign the throne to his uncle Charles, the only one of Gustav Vasa's sons who inherited any share of his legislative and administrative talents. The policy of Charles IX. was to encourage the burgher classes at the expense of the nobility, and by his successful efforts to foster trade—in furtherance of which he laid the foundation of Gottenborg and other trading ports—develop the mineral resources of the country, and reorganise the system of Swedish jurisprudence, he did much to retrieve the calamitous errors of his predecessors. The deposition of Sigismund gave rise to the Swedo-Polish war of succession, which continued from 1604 to 1660; and on the death of

Charles in 1611, his son and successor, the great Gustavus Adolphus, found himself involved in hostilities with Russia, Poland, and Denmark. By the ability of his minister, Oxenstierna, the young king was soon enabled to conclude treaties of peace with his northern neighbours, and to place the internal affairs of his kingdom in order (see GUSTAVUS II.); and although he justly ranks as one of the greatest military commanders of his age, the extraordinary number of benefits which he conferred on every department of the administrative system of S., entitle him to still greater renown as the benefactor of his native country. His death in 1632, on the field of Lützen, would have proved an irreparable calamity to S., had not the able administration of Oxenstierna, during the minority of Gustavus's daughter Christina, maintained the renown of the Swedish arms abroad, and the political reputation of the country among other states. The reign of Christina (q. v.) was a futility, and the most popular of her acts was her abdication. The short reign of Charles X. was occupied in generally unsuccessful wars against Poland and Denmark; while the minority and long rule of his son, Charles XI. —from 1660 to 1697—was characterised by success abroad, and in the augmentation of the regal power, which was declared by an act of the diet to be absolute. His son, Charles XII. (q. v.), succeeded, at the age of 15, to the power and dominions which his father's abilities had consolidated, but which, notwithstanding his own brilliant genius, he so deeply imperilled by his insatiable ambition, that at his untimely death in 1718, at the siege of Frederikshald, after a brilliant career of glorious but chequered military achievements, he left his country overwhelmed with debts, and disorganised by prolonged misrule. With him the male line of the Vasas expired, and his sister and her husband, Frederick of Hesse-Cassel, were called to the throne by election, but were the mere puppets of the nobles, whose rivalries and party dissensions plunged the country into calamitous wars and almost equally disastrous treaties of peace, and, under the leadership of the two great factions of the 'Hats,' or French party, and the 'Caps,' or Russian party, demoralised all ranks of society. The weak Adolphus Frederick of Holstein-Gottorp, who was called to the throne on the death of Frederick in 1751, and died in 1771, did little to retrieve the evil fortunes of the state; but his son, Gustavus III (q. v.) (1771—1792), skilfully turned to account the general dissatisfaction of the people with the nobles, to destroy the factions of the Hats and Caps, and to recover the lost power of the crown. His extravagance, dissoluteness, and insincerity detracted, however, from his merits as a ruler, and raised up numerous enemies against him, through whose agency he was assassinated in 1792. His son and successor, Gustavus IV. (q. v.), lacked the ability to cope with the difficulties of the times, and after suffering in turn for his alliance with France, England, and Russia, was forcibly deposed in 1809, and obliged to renounce for himself and his direct heirs the crown in favour of his uncle, Charles XIII., who saw himself compelled at once to conclude a humiliating peace with Russia by the cession of nearly a fourth part of the Swedish territories, with $1\frac{1}{4}$ million of inhabitants. The early part of the reign of Charles, who was childless, was troubled by domestic and foreign intrigues to regulate the choice of an heir to the throne; and when, under the erroneous idea of conciliating Napoleon, the dominant party in S. elected General Bernadotte to the rank of Crown Prince, the latter assumed the reins of government, and by his steady support of the allies against the French emperor, secured to S. at the congress of Vienna, the possession of Norway, when that country was separated from Denmark. Under the able administration of Bernadotte, who, in 1818, succeeded to the throne as Charles XIV., the united kingdoms of S. and Norway made great advances in material prosperity and political and intellectual progress; and although the nation at large entertained very little personal regard for their alien sovereign, his son and successor, Oscar (1844—1859), and his grandsons, the late king, Charles XV., and the present king, Oscar II., who came to the throne in 1872, have so identified themselves with their subjects that the Bernadotte dynasty has secured the loyal affections of every section of the united nations of S. and Norway.

SWEDENBORG, EMANUEL, a man of science, a philosopher, a theologian, and a seer, was born in Stockholm, Sweden, January 29, 1688, and died in London, March 29, 1772. His father, Jesper Svedberg, was a bishop of the established church of Sweden, whose family was ennobled by Queen Ulrika Eleonora, and the name changed from Svedberg to Swedenborg. This gave E. S. the rank of a nobleman. He was educated at the University of Upsala, where he graduated at the age of twenty-one. He then traveled for four years in England, Holland, France, and Germany. He had an ardent love for mathematics and mechanics, in which branches he was especially proficient. On his return to Sweden he was appointed by Charles XII. to an assessorship in the College of Mines. He enjoyed the intimate friendship of that monarch, to whom he rendered important services at the siege of Fredericks-hall, by transporting vessels over land on carriages of his own construction. At this period his mind was busy with various scientific subjects, upon which he published pamphlets from time to time, such as short treatises on algebra, giving the first account in Sweden of the differential and integral calculus; on a mode of finding the longitude at sea by the moon; on decimal money and measures; on the motion and position of the earth and planets; on docks, canals, salt-works, chemistry, bridges, air-guns, submarine vessels, the circulation of the blood, a new system of notation, and many other subjects. In 1724 he was offered the Professorship of mathematics at Upsala, which he declined. He now remained silent for eleven years; but the result appeared at Leipsic in 1734, in three massive folios beautifully illustrated, entitled *Opera Philosophica et Mineralia.* The first volume, called *Principia, or the First Principles of Natural Things, being new attempts towards a Philosophical Explanation of the Elementary World,* is an elaborate deduction of matter from 'points of pure motion produced immediately from the Infinite.' This was followed in 1734 by a treatise on *The Infinite, and the Final Cause of Creation.* The other two volumes describe the manufacture of copper, iron, and brass, and contain an exhaustive record of the best methods in use in last century. His investigations at this period were pursued with the expressed determination to discover the soul itself, and indeed to penetrate the whole realm of final causes. With this end he studied Anatomy and Physiology, and thereupon published in 1741 two volumes entitled *Œconomia Regni Animalis*, and in 1744—5 three volumes entitled *Regnum Animale.* The character, number, and variety of these works serve to shew the character, attainments, and purposes of the man, and to render still more striking his subsequent career.

Suddenly his scientific labors ceased, and in all his works afterwards published, he scarcely so much as alluded to them. He soon resigned his assessorship, and devoted himself exclusively to the labor which has since rendered him so celebrated. To give the substance of his own account of this transition, the

Lord appeared to him in an unexpected manner by the opening of his spiritual senses, and commissioned him to be the herald of a New Dispensation, or of the New Church signified by the New Jerusalem in the Revelation. As such, his office was to interpret the Word of God according to its true significance; to set forth a complete system of true religious doctrine; and finally, by daily intercourse for twenty-seven years with the spiritual world, to reveal its nature, its order, and the constant relation of all men to it. The result of all this was, the publication in Latin of a series of theological works, more voluminous than even his previous scientific productions. The first and largest is called, *Arcana Cœlestia; the Heavenly Mysteries contained in the Holy Scripture, or Word of the Lord, unfolded in an Exposition of Genesis and Exodus: together with a Relation of Wonderful Things seen in the World of Spirits, and in the Heaven of Angels*, 12 vols., published in London during 1749–56. Next came a volume entitled *Heaven and Hell, a Relation of Things heard and seen.* To these succeeded others, of which the following are abbreviated titles: *Earths in the Universe, with an Account of their Inhabitants: The Last Judgment: The New Jerusalem and its Heavenly Doctrine: The White Horse of the Apocalypse: Doctrine of the New Jerusalem respecting the Lord:* and similar treatises on *The Sacred Scripture*, on *Life*, and on *Faith: Divine Love and Wisdom: Divine Providence: Apocalypse Revealed* (2 vols.): *Conjugial Love: Intercourse between Soul and Body: True Christian Religion.* His posthumous works are *Apocalypse Explained* (6 vols.): and other smaller ones. These books leave scarcely a point in theology, or even any important subject of human thought, untouched or unaltered. According to their general tenor, God is the only, and the original Substance and Form—this Substance being Love, and its Form, Wisdom; together they emit a creative and preservative Sphere (which appears in the spiritual world like a Sun), that operates forever upon all beings and things. And thus we have an abstract expression of the Divine Trinity—Love, Wisdom, Use—the three being inseparably one, each essential to the others and yet perfectly distinct. They involve the Doctrine of Degrees; for each is graduated from centre to circumference as light declines to shade; this is the Continuous Degree, or Continuous Gradation: again, one is evolved in order from the other, and envelops the other, like end, cause, and effect; yet love is not wisdom, neither is wisdom use; this exhibits the Discrete Degree, or Distinct Gradation. This trinal and graded structure of things is universal, *in maximis et minimis.* There are consequently three heavens; in the highest, love predominates; in the second, wisdom; in the third, use: and three hells; in the deepest, self-love predominates; in the second, self-derived wisdom; in the third, self-service. Every man is created in the same order; he is love, wisdom, and their use (or their active operation in producing effects), a spiritual organism, clad with a material body, which he puts off at death, and never resumes again,—thereby entering that heaven or hell with which his character is homogeneous. The soul is the real man.—Less abstractly, God is the Infinite Man, the Soul of all souls, the Prototype. He is Life itself. Love is Life. He assumed Humanity in Christ, in whom His Love is the Father, His Wisdom the Son, and their proceeding sphere the Holy Spirit. Christ is therefore the Triune God. The trinity of Persons is an error. Because God is the Infinite Man, every man is a man, every angel (all angels were first created men), every devil, every society of either, and all heaven, or all hell, in the aggregate, is in organization a man. But hell is deformed, and heaven beautiful. Finally, for the same reason, the outer universe is representative of man. 'Like begets like. All beings and things are receptacles of the influent Divine Life, and receptacles only; they have life and being only by a constant interior communication from God. Man's individuality and freedom are from the same source. 'Existence is perpetual subsistence.' 'Preservation is perpetual creation.' God made man innocent. Appearances, by appealing to his lower and sensual faculties, beguiled him from the love and knowledge of God, and the race gradually became wicked. This is the Fall. After death wicked men formed infernal societies. This is the origin of hell, which is called the devil. There is no other devil. Hell thus enlarged itself; and heaven, consisting of associations of the good, grew relatively weak. God then assumed Humanity to reach hell in externals, where its power was fixed. By a life of wonderful inward significance, wherein he overcame all possible temptations, He subdued hell, restored heaven to order, re-established the Church, drew nearer to men on earth, and thus wrought redemption, which is essentially man's deliverance from evil, by giving him communication with God. Since the fall, man naturally tends to self-love, the synonym of evil; he must therefore be reformed and regenerated. He is reformed by learning what is good and true, and acting accordingly in opposition to his evil tendencies. Into this improved mode of thought and action on man's part, the Divine Love and Wisdom can freely flow, and vivify him with all good affections, and enlighten him with wisdom. This is regeneration. The regenerate form heaven. All infants also go to heaven, and are tenderly reared by the angels. They grow up to angelic manhood and womanhood. The origin of sex is in the soul. Therefore in heaven they live in marriage with indescribable happiness. Promiscuity prevails in hell, which in all respects is the exact opposite of heaven, as falsehood is of truth, or evil of goodness. Heaven and hell are eternal, and counterbalance each other. Between them is an intermediate state, upon which all enter at first after death, staying long enough to put off all that does not belong to their life's love, and then going, in accordance with this love, to their own, in heaven or in hell. God does not hate and torment hell. He is Love, and cannot. He loves all equally, and gives Himself to all alike; but all do not receive Him alike. He makes heaven blissful by His presence, and ameliorates the condition of hell by a superintendent mercy and restraint. The sufferings of hell are the legitimate effects of its intense lusts and selfishness. The spiritual world is not far off. It is simply the world of spirit, where all spirit always is. To enter it is to have the spiritual senses opened, as happens sometimes in life, and always at death. Time and space belong not to it, but to Nature. Spiritual time and space are internal states of wisdom and love; but they are to the spirit precisely what natural time and space are to the body. The two worlds communicate by correspondence only. Thus heat and light correspond to love and wisdom, which are spiritual heat and light; and everything in either world is similarly correspondent to something in the other. The universe is thus all representative, and full of sublime significance. The Sun is representative of the Lord; the earth of man; and so on. The Word is written by correspondences, a knowledge of which S. was called to restore; it therefore connects heaven and earth, God and man, and contains a spiritual and a celestial sense within that of the letter.

These and other general statements are wrought out in S. with great variety and copious illustration. To this work he confined himself, making no effort to organize a church on the basis of the

new doctrines. Personally, he was modest and retiring, but genial and happy, and lived a life of extreme simplicity. He was never married. Since his death, organizations of those who believe his theological writings to be the Lord's Second Coming as spiritual Truth unfolded from the Word of God, have been formed both in England and America, the majority of which societies are again united in general bodies, known in England as the General Conference, and in America as the General Convention, of the New Church. There are other societies and individuals holding the same views not connected with these bodies. S.'s writings are also esteemed of the highest value by many who accord to him no special authority. All together are not numerous, but they include in their ranks much worth and intelligence, and many noted names both in Europe and America.

Several biographies of him have been written, among which the most widely-known are those of Wilkinson, White, and Hobart. Societies have been formed at different times, both in England and America, for the publication of his theological works, and one of these also published the more important of his scientific works in a very fine translation. Many of the former works have also been translated into French and German, and are now being translated in Norway and Sweden. A new edition of them, in a new translation, and in very handsome style, is now in the course of publication by J. B. Lippincott & Co., of Philadelphia. This edition is designed to be complete, and will comprise about forty volumes *demi-octavo*.

SWEDISH LANGUAGE AND LITERATURE. See SCANDINAVIAN LANGUAGE AND LITERATURE.

SWEEPS, on Shipboard, are oars of great length used in large vessels during a calm, to enable the ship to obtain steerage-way.

SWEET BAY. See BAY.

SWEET BRIER. See ROSE.

SWEET FLAG. See ACORUS.

SWEET GUM. See LIQUIDAMBAR.

SWEET-MEAT, a general term applied to such articles of food as consist chiefly of sugar. An almost infinite variety of preparations of the confectioner come under this term.

SWEET PEA. See LATHYRUS.

SWEET POTATO. See BATATAS.

SWEETS, a term applied in England, and by the Board of Inland Revenue, to home-made wines, for the sale of which a special license is granted. It is also a term in far more general use for lozenges, comfits, and other preparations of sugar well known to children; they are the *confitures* of the French.

SWEET SOP (*Anona squamosa*), a fruit of the same genus with the Custard Apple (q. v.). It is produced by a small bush, with lanceolate leaves, a native of the warm parts of America, and much cultivated in Brazil, the West Indies, and generally in tropical countries. The fruit is greenish, and resembles an artichoke in size, in form, and in its scaly covering. The pulp is soft, somewhat mealy, sweet, and luscious; with a musky aromatic odour and flavour. It is much used both in the East and West Indies, generally raw, but sometimes cooked. Notwithstanding its foreign origin, it has proved the staff of life to the people of Hindustan in seasons of famine. The seeds are acrid, and the powder of them is used to destroy insect vermin.

SWEET WILLIAM. See PINK.

SWEET WOOD. See CASCARILLA.

SWELL, in Music, a set of pipes in an organ with a separate key-board, and forming a separate department, which are capable of being increased or diminished in intensity of sound, by the action of a pedal on a series of shades or shutters overlapping each other like Venetian window-blinds, within which the pipes in question are enclosed. On a well-constructed swell, a practised performer can imitate not only a gradual *crescendo* and *diminuendo*, but also a *sforzando*, a very small opening sufficing to make an immediate burst on the ear; while, when the shutters are closed, an imitation of an echo is produced.

SWIETE'NIA. See MAHOGANY.

SWIFT (*Cypselidæ*), a family of birds of the division *Clamatores*. The distinctive characters of the group, of which the true Swifts are the type, are noticed in the article SWALLOW. The swifts, like the swallows, are widely distributed, and some are only found in tropical countries; others are birds of passage, and spend the summer in colder parts of the world. Many of the S. group are often popularly called swallows, as that which produces the edible nests of the East Indies. In the genus *Cypselus*, as now restricted, the tail is generally forked, the legs and toes feathered, and very small and weak, all the four toes directed forwards. The birds of this genus pass most of their time in the air, and even copulate on the wing. The wings are longer than in any other bird; and the internal structure, even of the skeleton, is peculiarly adapted to prolonged flight. The anatomy more resembles

Common Swift (*Cypselus apus*).

that of humming-birds than of true swallows.—The COMMON S. (*C. apus*) is common in almost all parts of the north of Europe and of Asia in summer, retiring to tropical or subtropical regions in winter. It occurs even in Lapland. Its residence in its summer quarters is much shorter than that of swallows; and it is worthy of notice, that the S. is seldom to be seen along with any of the swallows or martins, the different kinds choosing different localities, even although very close together. The S. is easily recognised in its flight by the remarkably sickle-shaped wings, and its slight scream is very different from the twitter of the swallow. It is black, with a white throat. It makes its nest in holes of rocks or of walls, often in those of houses. The nest is formed of bits of straw, dry blades of grass, and bents, feathers, and other such substances, which are apparently glued together by a mucous secretion. The S. sometimes builds in hollow trees. Swifts, like swallows, seem to return to the same

place to make their nest, year after year, and repair the old nest, instead of making a new one.—The ALPINE S., or WHITE-BELLIED S. (*C. alpinus*), is rarely seen in Britain, but is common in the more southern countries of Europe. It builds in high rocks, sometimes in steeples. It is larger than the Common S., and is the largest of the British *Hirundinidæ*. Its wings are even longer in proportion than those of the Common Swift. Its voice is sweet, not a scream like that of the Common Swift. —The AMERICAN S. (*Chætura pelasgia*) has the hind-toe directed backwards, and the tail-feathers stiff and pointed, as in woodpeckers. It is a small bird, not above 4¾ inches in entire length, but 1 foot in extent of wing. The general colour is brownish black, with greenish reflections, the throat grayish white, the under parts grayish brown. The nest is made of small dry twigs, which the bird breaks off from the tree, and carries away in its feet; and they are attached by means of the saliva, to the rock, wall, or hollow tree where the nest is made. From its frequently building in chimneys, this species is known as the *Chimney Swallow* in North America. Great numbers often build together, sometimes choosing for this purpose an unused chimney in a town.

SWIFT, JONATHAN, the greatest of English satirists, and the most original writer of his age, was born in Dublin, but of English parents, on the 30th of November 1667. He was a posthumous child, reared amidst circumstances of abject poverty and dependence, the recollection of which galled his proud irascible spirit, and embittered much of his future existence. He was supported by relatives, and educated at Kilkenny school and Trinity College, Dublin. He proved a negligent and turbulent student, more intent on personal satires and political rhymes than academical honours; but he remained at college about seven years. He then removed to England, visited his mother in Leicestershire, and by her recommendation was admitted into the house of Sir William Temple, who had long known the Swift family. He seems at first not to have conciliated the regard of the retired minister, for in the following year (May 1690), Temple made an offer of the services of his protégé to Sir Robert Southwell (then about to proceed to Ireland as Secretary of State), recommending him as diligent and honest, qualified either to wait on Sir Robert as a gentleman, or to write under him as a clerk. No appointment followed; S. remained with Temple, studying hard, till 1694, when he went to Ireland, took orders in the church, and obtained a small living, which he threw up in two years, and returned to England, in consequence of Temple, who missed his society and assistance, urging him to come back. Temple died in 1698, and S. in the following year, published his posthumous works, after which he again repaired to Ireland, obtaining from Lord Berkeley some church preferments, including the vicarage of Laracor, worth in all about £400 per annum, which was all the professional income he enjoyed till he was appointed Dean of St Patrick's, in his 46th year. Before this, he had written the wildest and wittiest and most powerful satirical work of the 18th c., *The Tale of a Tub* (1704), also a few essays on ecclesiastical subjects, some inimitable ridicule of astrology under the name of Isaac Bickerstaff, and poetical pieces possessing a peculiar vein of humour and description. In 1710, he went over to the Tories, conceiving himself neglected by the Whig ministers, and exerted himself strenuously in behalf of his new allies, Harley and Bolingbroke. He wrote papers in *The Examiner* (1710); a *Letter to the October Club* (1711); *The Conduct of the Allies* (1712); *The Barrier Treaty* (1712), and innumerable pasquinades against the Whigs, whom he 'libelled all round.' He had become, as it were, a great and formidable power in the state, yet could extort no higher preferment for himself than the deanery of St Patrick's. His party was overthrown by the death of Queen Anne; and in 1714, S. 'commenced Irishman for life,' with strong reluctance and disgust. In time, however, he took interest in Irish affairs, and identified himself with Irish feelings and prejudices. Hatred to Walpole and the English government quickened his activity; and his resistance to Wood's copper coinage—a scheme for supplying Ireland with copper money by an English patentee—raised him to the highest pinnacle of popular favour. His *Drapier Letters* (1724) produced quite a ferment in Ireland, and compelled the government to abandon the scheme of the coinage. Two rewards of £300 each had been offered for the unmasking of the Drapier, but not a traitor, as he says, could be found to sell him. The triumphant author made his last visit to England in 1726, and published his *Gulliver's Travels*, the most universally popular of all his works. He next joined with Pope, Arbuthnot, and Gay in publishing three volumes of *Miscellanies*, after which he returned to Ireland (October 1727), and never left it again. He was subject to fits of giddiness and deafness, which increased in frequency and intensity as he grew old; he brooded over the anticipated madness which he foreboded would be his future lot; his temper, always irritable and gloomy, became more violent and morose, the effect of cerebral disease, and his memory and other faculties gave way. There was also a deep and secret grief: the fate of two ladies, known as Stella and Vanessa, had been inseparably entwined with his own destiny; both had sacrificed for him all but honour, and had sunk under disappointed hopes and blighted affection. We cannot here trace the painful story, which is still involved in mystery, but for a time the retribution of S. was terrible. He rallied, however, and wrote some of his best minor pieces after this period. Among these are *The Grand Question Debated; On Poetry, a Rhapsody; The Legion Club; Verses on the Death of Dr Swift;* and that extraordinary prose tract, *The Modest Proposal*, a masterpiece of irony, in which he proposes to relieve the distresses of the poor Irish by converting their children into food for the rich. The last three years of S.'s life were passed in almost total silence in the hands of keepers. He died October 19, 1745.

It would be superfluous to attempt in our brief space to characterise the genius of the immortal Dean of St Patrick's. Shakspeare alone among English authors has received a greater amount of criticism and annotation. From Johnson to Thackeray, the most brilliant critics and biographers have employed themselves in elucidating his strange and sad history, and in estimating his writings. As a consummate master of ridicule and irony, possessing great powers of wit, invention, illustration, and analogy; possessing also the dramatic faculty that enabled him to assume and portray varieties of character; and as writing a pure, perspicuous English style, unsurpassed for strength and simplicity, S. must ever be a model in our language and literature. His misanthropy, or degradation of human nature—his Yahoos, Strulbrugs, daring irreverence, and indelicacy, are of course indefensible. He had a total incapacity, as De Quincey remarks, for 'dealing with the grandeurs of the human spirit, with religion, with poetry, or even with science, when it rose above the mercenary practical.' His business was with the world—with the follies, vices, and absurdities of men. And his poetry is the same as

his prose; it may come under his definition of a good style, 'proper words in proper places,' applied to ordinary topics, but is wholly wanting in passion, elevated feeling, and imagination. A complete edition of his works (with a biography), in 19 vols., was published by Sir Walter Scott (1815). See also Roscoe's edition (2 vols. 1853).

SWI'LLY, Lough, an inlet of the Atlantic on the north coast of Ireland, in the county of Donegal, enters between Dunaff Head on the east, and Fanad Point, on which there is a light-house, on the west. It penetrates the country in an irregular, but generally south direction, is about 25 miles in length, and at its entrance, where it is widest, it is 3¾ miles broad. On the eastern shore is the small town of Buncrana, which is resorted to by considerable numbers for sea-bathing; and in front of which is a commodious roadstead, capable of accommodating the largest men-of-war.

SWIMMING. The art of swimming is so exceedingly useful, not only as a bracing summer exercise, but as a means of preserving life, that it should be acquired by every young person. Considering the numerous risks run by all human beings, especially by the inhabitants of maritime countries, of being accidentally plunged into the water; and how greatly the chances of being saved are increased by the power of keeping one's self afloat for even five minutes, it is surprising that the art of swimming does not form an essential element of education among all classes. With our limited space, it would be needless to attempt giving directions that would be of any practical value. In many cities, there are now swimming-schools, where professional instruction may be had. When these are not available, any acquaintance who can swim will give his aid until the elementary movements and the necessary confidence are acquired. Even without assistance, by keeping in safe water, and by determined perseverance, the art will be acquired as by instinct. The principles of the art will be found explained in Chambers's *Information for the People*—'Out-of-door Amusements.' See also Routledge's *Handbook of Swimming and Skating*; and *The Boy's Own Book*.

SWI'NDON, an old market-town of Wilts, 77 miles west of London by the Great Western Railway. It contains a handsome church, large corn exchange, and excellent shops. About a mile north of the town is Swindon Junction, the great central establishment and manufactory of the Great Western Railway Company. The engine dépôt here is capable of accommodating 100 engines, and a number of engines and tenders are always kept ready for action, for here every train changes its locomotive. A considerable town has risen around the station, called the New Town, and consisting for the most part of dwellings for the employés of the railway. There are also a large and remarkably beautiful church, a public park, library, and mechanics' institution. Pop. of Old Town (1881), 4696; of New Town, 17,669.

SWI'NEMUNDÉ, a maritime and fortified town of Prussia, province of Pomerania, is situated on the island of Usedom, at the entrance of the narrow channel of Swine, which connects the Grosse Haff (into which the Oder flows) with the Baltic. S., as in some sense the port of Stettin (q. v.), carries on a considerable commerce, and has also valuable fisheries, but it is chiefly noted for its excellence as a bathing-place, being, next to Dobberan, the most frequented town in this respect on the Baltic. Its agreeableness as a sea-coast residence is enhanced by the beauty of the environs. S. has regular steam-communication with Stettin (daily), Rügen, and Copenhagen. The population of this port is said to be about 10,000.

SWING, a cognomen assumed by senders of threatening letters during the period when the irritation of the agricultural labourers of England against their employers was at its height—viz., from 1830 to 1833. The cause of this misunderstanding arose from a widespread belief on the part of the labourers, that the use of machinery, especially of thrashing-mills, would greatly lessen the demand for labour, and consequently produce a general reduction of wages; it was also intensified by the savage severity with which the game-laws were enforced, and by other hardships to which the labouring-classes in the country considered themselves unjustly subjected. The ordinary mode of procedure by these terrorists was to send a letter to the obnoxious farmer or landlord, complaining of his conduct, and demanding the adoption, without delay, of a more liberal course towards his workmen—either by raising their wages, giving up the use of his thrashing-machine, &c., as the case might be—and, in default of compliance, threatening destruction to his property—a threat which was in general amply executed. For months together, the destruction by fire of stacks, farm-buildings and machines, and live-stock, was of nightly occurrence; and so terrified did the employers of labour soon become, that implicit obedience was paid to the dictates of 'Captain Swing;' many even who had not been favoured with a notice from this unseen 'reformer,' hasted to profit by the sad experience of a neighbour, and avert the wrath of the inevitable avenger from their own heads by at once raising the scale of wages. It is not to be wondered at that with such encouragement 'Swings' became numerous, and their demands more insolent; but the apprehension and punishment of a number of them gradually brought about a cessation of the outrages. It was a current belief at the time that they were due to the agency of secret revolutionary agents; but it subsequently appeared that in the great majority of cases no such incitements had been employed.

SWITHIN, Saint, an English ecclesiastic of the 9th c., who was chaplain to King Egbert, and tutor to his son Ethelwulf, under whom, when he came to the throne, he held the office of Chancellor. He had the charge of the education of King Alfred, whom he accompanied to Rome. In 852, he was consecrated Bishop of Winchester. According to William of Malmesbury, he was 'a rich treasure of all virtues, and those in which he took most delight were humility and charity to the poor.' He adds, that he built several churches, and travelled through his diocese with his clergy on foot, and for the most part by night, in order to avoid the appearance of ostentation. The origin of the tribute called 'Peter-pence' (q. v.) has been often assigned to S., and he is said to have procured an act of the Wittenagemote, enforcing, for the first time, the universal obligation of paying tithes. S. died on 2d July 862, and was buried, according to his own desire, in the church-yard of Winchester. A century later, he was canonised; and the monks, not considering this a fitting place of sepulture for a saint, exhumed his body, for the purpose of depositing it in Winchester cathedral; but this translation, which was to have taken place on the 15th July, was delayed in consequence of violent rains, which continued without intermission for forty days. Out of this circumstance arose the still current belief, that if rain fall on the 15th July, it will continue to rain for forty days. Experience certainly shews, that when a period of wet weather sets in about the summer

solstice, it generally proves of considerable duration; and we find a similar superstition popularly attached in different countries of Europe to the festivals of various saints, which occur about the same period of the year. In France, the watery saints' days are those of St Médard (8th June), and St Gervais and St Protais (19th June), the meteorological canon being—

> S'il pleut le jour de Saint Médard,
> Il pleut quarante jours plus tard;
> S'il pleut le jour de St Gervais et de St Protais,
> Il pleut quarante jours après.

The rainy saint in Flanders is St Godelieve, and in Germany there are three saints' days to which this belief attaches, one being that of the Seven Sleepers.

SWITZERLAND (Ger. *Schweitz;* Fr. *Suisse;* It. *Svizzera*) is an inland country of Europe, situated between 45° 48′—47° 49′ N. lat., and 5° 55′—10° 30′ E. long. Its greatest length from east to west is 180 miles, and its greatest width from north to south, 130 miles. Its superficial area is 15,721 square miles, or one-fourth that of England and Wales. The following table shews the area and population (according to the census taken December 1, 1880) of the cantons into which Switzerland is divided:

Cantons.	Area in Eng. Square Miles.	Pop. Dec. 1880.
Zürich	659	317,576
Bern	2,615	532,164
Lucerne	480	134,806
Uri	418	23,694
Schwyz	358	51,235
Unterwalden {Upper and Lower}	298	27,348
Glarus	265	34,213
Zug	91	22,994
Freiburg	632	115,400
Soleure	292	80,424
Basel {Town and District}	181	124,372
Schaffhausen	118	38,348
Appenzell {Exterior and Interior}	163	66,799
St Gall	781	210,401
Grisons	2,706	94,991
Aargau	538	198,645
Thurgau	384	99,552
Tessin, or Ticino	1,082	130,777
Vaud	1,226	238,730
Valais	2,016	100,216
Neufchatel	308	103,732
Geneva	110	101,595
Total	15,721	2,846,102

Surface.—S. is the most mountainous country of Europe. Its principal chains are the Alps (q. v.) and the Jura (q. v.). The former run from east to west along its southern or Italian frontier. Their ramifications fill more than one-half of the country, and terminate along a line which may be traced from Vevey, on the Lake of Geneva, to Mount Moleson and Mount Napf, across Lake Zug, to the southern shores of the lakes of Zürich and Wallenstadt, and Sargans on the Rhine. The mean elevation of the highest chain is from 8000 to 9000 feet. The Jura run north-east from the western corner of Switzerland. They consist of a series of parallel ridges enclosing long and narrow valleys, and their mean elevation does not exceed 4000 feet. In the angle formed between them and the Alps, lies the plain of S., a tableland 100 miles in length, and from 20 to 30 miles in width, with a mean elevation of about 1400 feet above the sea. It is not absolutely level, but covered with elevations, which seem very unimportant, however, when contrasted with the huge masses of the Alps and Jura. It has been described, and not inaptly, as a corner of Southern Germany, penetrating like a wedge between France and Italy. The communication between the plain of S. and the German valleys of the Danube and Rhine is not, however, continuous. The plain on the east terminates in a third hilly tract—the Thur hill-country, which lies between the lakes of Zürich and Constance, and which, to some extent at least, forms a barrier between the plain of S. and Germany. The Jura, the plain, and the hill-country are, then, the great divisions of Northern Switzerland. The divisions of the Alpine region are more strongly marked in nature. A glance at the map will shew that the chains which overspread it radiate from a mountain knot lying to the west of the Grimsel Pass. They isolate and enclose (1) the valleys drained by the Rhone, which connect S. with Southern France; (2) Ticino, drained by streams which descend to the Po, and have at all times brought this country into close communication with Italy; (3) The Grisons, the most sequestered valleys of Switzerland, drained by the tributaries of the Rhine and Danube, and shut out by mountains from the lower basins of these rivers; (4) The Bernese Oberland, which slopes towards the western extremity of the Swiss plain; (5) The district of the Forest Cantons—Schwyz, Uri, and Unterwalden—surrounding the Lake of Lucerne, and which slope towards the eastern extremity of the plain, and seem a great mountain fortress erected in the very heart of Switzerland, to protect the plain against German invasion.

Geology is of little importance in explaining the general geography of Switzerland. It may, however, be stated that in the Southern Alpine region, the rocks are crystalline; that in the Northern Alpine region, they belong to the Jurassic and other Upper Secondary strata; and that in the plain and a great part of the hill-country, they consist of loose Tertiary sands and clays, which supply the best agricultural soils of Switzerland. Those rocks and formations in which mines and coal chiefly abound are absent.

Climate.—In S., the climate chiefly varies with elevation above the sea-level. At a height exceeding 9500 feet, the mountains are covered with perpetual snow, which descends along the hollows in Glaciers (q. v.) to a much lower level, and in this way covers the elevated part of the country with a vast sea of ice. Below the level of perpetual snow, the surface of S. has been divided into a series of belts, characterised by different climates and productions. The highest of these, lying between the snow and the level of 6900 feet has been called the Upper Alpine region. In it the glaciers fill the valleys, but plants clothe the scanty soil of the ridges. The second or Lower Alpine belt descends to 4800 feet. It is a country of pastures, in which shrubs but no trees make their appearance. The Righi Pass, the Grimsel Hospice, and the Splügen are included in it. The third belt descends to 4350 feet. The meadows still abound in it, but forests of firs and maples in many parts replace them. It includes Urfenthal and Oberengadin. The fourth belt sinks to 3000 feet. The forests still abound, the beech being the prevailing tree. The meadows are excellent, and rye and barley are successfully cultivated. It includes Weissenstein, Grindelwald, and Engelsberg. The fifth belt lies above 1800 feet. In it the oak and walnut are the characteristic forest trees. Spelt and the best wheat are cultivated. It includes Bern, Coire, and St Gall. The last belt sinks to 750 feet. In it the chestnut is the characteristic tree; the mulberry and the vine are extensively cultivated, and wheat is the grain chiefly grown. This belt includes the

greater part of the Swiss plain, and sinks to its lowest level in the Valley of the Rhine, between Constance and Basel, and the banks of Lake Zürich and the Lago Maggiore. In the last district, the vegetation is that of Northern Italy. At a higher elevation than 6400 feet, S. is only inhabited by herdsmen during the summer months. At this limit, however, permanent abodes begin to make their appearance; and at 4000 feet there are many villages. The most populous part of S., however, lies between 1250 and 2150 feet. The temperature of this region is fairly represented by that of Zürich, which we will compare with that of London. The temperature of Zürich is in winter 30·34°; in spring, 47·25°; in summer, 64·15°; in autumn, 49·05°: for the year, 47·95°. The temperature of London is in winter, 38·22°; in spring, 48·34°; in summer, 61·74°; in autumn, 50·29°: for the year, 50·50°.

Productions.—In S., where good coal is not to be had, and where the houses are built of wood, the forests, which cover one-sixth of the whole surface, acquire very great importance. Wood-cutting is one of the chief employments of the people. The trees cut down in the highlands are deprived of their branches, and shot with inconceivable rapidity over the slopes to the valleys below, whence they are removed by rafts, not only to different parts of S., but to France and Germany. It is, however, the mountain-pastures and the meadows, forming two-fifths of the whole surface of the country, that supply the chief occupations of the people—those of herdsmen and shepherds. During the summer, the cattle are driven into the mountains, and tended by herdsmen, who take up their abode in the rude wooden huts known as *chalets*, and there the butter and cheese are made. In summer, it is estimated that there are in S. upwards of a million of horned cattle, one-fourth of which consists of milch cows. The produce of the dairy annually is valued at between one and two millions sterling. The best breeds of cattle are those of Saanen and Simmenthal in Bern, Gruyères in Freiburg, Schwyz, Zug, Entlebuch, Pralligau in the Grisons, and Glarus. The best cheese is made at Emmen, Saanen, Simmenthal, Gruyères, and Ursern. The sheep of S. are of inferior breed, and their wool is short and coarse; but the goats are numerous and fine. More than two-thirds of S. does not supply corn enough to feed its inhabitants. The plain, however, is a fertile agricultural country. In Vaud and Neufchatel, the cultivation of the vine is the chief occupation of the people; and in the Thur hill-country, more particularly on the shores of the Lake of Constance, there are extensive orchards, in which are prepared cider and *kirschwasser*, the latter being a liquor largely consumed in Switzerland. It will give some idea of the extent to which S. is cultivated to state, that out of every 100 sq. m. of surface, 30 are occupied by rocks, glaciers, and water; 20 by hill-pastures; 17 by forests; 11 by arable lands; 20 by meadows; and 1 by vineyards. In the uncultivated part of the country, the bear, the wolf, and the larger birds of prey are still met with; and the Chamois (q. v.) is hunted. The rivers and lakes abound with fine fish, and more especially with trout.

Manufactures.—The manufacturing districts are not scattered over the whole surface of the country; they are met with only on the northern frontier. The chief manufactures are: at Zürich, silk-stuffs, to the value of £1,600,000 annually, and cottons; at St Gall and Appenzell, cottons; in Aargau and Glarus, cottons, linens, silks, and hosiery; at Basel, silk-stuffs to the value of £1,400,000, leather, paper, and tobacco; in Aargau and Lucerne, straw-plaiting; in Neufchatel, watch-making and cotton-printing; in Geneva, watch-making and jewellery. Although S. is inland, its commerce in proportion to population has long exceeded that of any other continental country. The chief imports are corn, salt, salt-fish, raw silks, and cotton, fruits and tropical produce, and the metals employed in watch-making. The exports are wood and charcoal, cattle, tallow, cheese and butter, silks and cottons, watches and jewellery. Internal communication has long been facilitated in S. by excellent roads, and every advantage has been taken of the lakes to introduce steam-navigation. The plain is now overspread from one end to the other with a network of railways, thus connecting closely all parts of the country. On Jan. 1, 1870, 840 miles of railways and 2870 miles of telegraph lines were in operation.

Government.—Hitherto, the Swiss have been very much split into distinct communities by the great mountain-chains which separate the cantons. One of the results has been the weakness of the central power. Each valley has been intrusted with the making of its own laws, and the management of its own local affairs. The cantons are, in fact, to this day in a great measure separate states. They are divided into two classes, absolute democracies and representative democracies. In the former, the chief power belongs to the *Landesgemeinde*, an assembly of the whole adult male population, which meets once a year, to pass laws, and to regulate the taxes and expenditure of the canton. Uri, the Unterwaldens, Appenzell, and Glarus have constitutions of this kind. In the Grisons and the Valais, the people may be said to possess similar powers, as all measures must be approved of by them. In the other, the representative cantons, a great council is elected by the people, and to it are deputed most of the powers of the Landesgemeinde. These local assemblies produce a remarkable effect on the Swiss people. Their debates have an importance far beyond that of an English town-council, or even of a colonial parliament, for their power is infinitely greater, and the population are more immediately interested in them. To the interest they excite is no doubt to be attributed in a great degree the intelligence and public spirit of the Swiss. Their greatest disadvantage lay in the power they formerly had to levy war against each other, and to resist the general government in conducting the foreign policy of the country. But these defects have been to a great extent remedied by the new constitution, which came into operation in 1848. It handed over the control of the army, the conduct of foreign affairs, the settlement of disputes between the cantons, and the management of the police and post-office, to a federal assembly (*Bundes Versammlung*) representing all the cantons. How far this assembly is entitled to interfere with the legislative action of the cantons, has not been very distinctly defined, but the tendency of legislation since its formation has been rather to trench than otherwise on their prerogatives. The federal assembly consists of two chambers, 1st, the State Council (*Stände rath*); 2d, the National Council (*National rath*). The former is composed of 44 members, 2 representing each canton; the latter, of 120 members, elected by the cantons in the proportion of 1 to 20,000 inhabitants. These bodies depute the executive authority to the federal council (*Bundes rath*), consisting of seven members, and holding office for three years. The president is merely one of the council, and he has none of the quasi-royal privileges of the American president, whose functions are discharged by the whole council. Different systems of law still prevail in the different cantons, which to some extent resemble each other, the most of them having grown out of the old German codes. Except in a few

frontier cantons, the Roman law has not been much regarded. In recent times, trial by jury has been introduced, but in the Catholic cantons the codes of law carry us back to the middle ages; they still prescribe for certain offences various degrees of corporal punishment, exposure on the pillory, and public penance in the churches. (See Rumbold's *English Government Report on the Penal Laws of Switzerland*, 1865.) In S. property is much subdivided, and this has exercised a very marked effect on the population. Of 485,000 heads of families, no less than 465,000 possess landed property. In the absence of great landed estates, there is no powerful aristocratic class. There are no titles of Swiss origin, families possessing such distinctions deriving them from abroad.

There is no standing army in S., but every citizen is obliged to serve as a soldier, and military drill is taught at all the schools. The Swiss regular force numbers 85,563; the reserve, 50,146. The whole expense of the military establishment was, in 1869, about $512,350. The national revenues in the same year amounted to $4,400,000, and the expenditure to $4,348,000.

Language and Religion.—In the sequestered valleys of the Grisons, two-thirds of the population still speak a Latin dialect known as the Romaunsh; Italian dialects have penetrated up the valleys of Ticino; French patois has invaded Western S., by the Rhine and the valleys of the Jura, to Laufen, the frontier of Soleure, Lake Morat, the Upper Saane, and Siders in the Valais. In the rest of S., the dialects are German. Of every 1000 Swiss, 702 speak German, 226 French, 55 Italian, and 17 Romaunsh. The Swiss Reformation spread chiefly from Basel, Bern, and Geneva, and the chief Protestant districts are the countries communicating with these towns. The Alpine region is almost entirely Roman Catholic, the seven Catholic cantons being Lucerne, Zug, Schwyz, Uri, Unterwalden, Valais, and Ticino. Out of 1000 Swiss, 411 are Roman Catholics, 587 Protestants, and 2 Jews.

Education.—In no country is elementary instruction more widely diffused. Parents are compelled to send their children to school from five to eight, but not above that age. There are universities on the German model at Basel, Bern, and Zürich, and academies on the French plan at Geneva and Lausanne. The number of clubs for scientific and literary, musical and social purposes, is most remarkable. There are no pursuits to which a class of men can devote themselves which are not represented by societies in Switzerland. The local political assemblies and other public meetings give ample employment to the newspaper and periodical press. In S. there are accordingly 188 political journals, and 167 periodicals devoted to literature and science. There are 40 daily papers. This active intellectual life is, however, chiefly confined to the Protestant cantons.

History.—S. was in Roman times inhabited by two races—the Helvetii, supposed to have been Celts, on the north-west; and the Rhætians (of whose origin we know nothing) on the south-east. After the conquest of Gaul, both races adopted the language and habits of Rome. When the invasions took place, the Burgundians settled in Western S.; while the Alemanni, another Germanic tribe, took possession of the country east of the Aar. A third Teutonic people, the Goths, entered the country from Italy, and took possession of the country of the Rhætians, which nearly corresponded with the Grisons. The Burgundians adopted Christianity in the end of the 5th c.; the Helvetii retained their old pagan creed until the 7th c., when they were converted by Irish monks, who founded abbeys and churches, which survive to our own time. S., in the early part of the middle ages, formed part of the German Empire, and feudalism sprang up in the Swiss highlands even more vigorously than it did elsewhere. During the 11th and 12th centuries, the greater part of S. was ruled on behalf of the emperors by the lords of Zähringen (q. v.), who did much to check civil wars, and to promote the prosperity of the towns. They, however, became extinct in 1218, and then the country was distracted by wars, which broke out among the leading families. The great towns united in self-defence, and many of them obtained imperial charters. In 1273, Rudolf of Hapsburg, a Swiss nobleman who had favoured the independence of the towns, became emperor. After doing so, he continued the same policy; but his son, Albert I. (q. v.), took another course. He attacked the great towns, and was defeated. The leading men of the Forest Cantons, which for ages had yielded a merely nominal recognition of the empire, and had acknowledged no feudal superior, met on the Rütli meadow, on 7th November 1307, and resolved to expel the Austrian bailiffs or landvögte. See TELL. The war terminated in favour of the Swiss at Morgarten in 1315. Schwyz, Uri, and Unterwalden, with Lucerne, Zürich, Glarus, Zug, and Bern, eight cantons in all, in 1352, entered into a perpetual league, which was the foundation of the Swiss Confederation. Other wars with Austria followed, which terminated favourably for the confederates at Näfels (q. v.) and Sempach (q. v.). In 1415, the people of the cantons became the aggressors. They invaded Aargau and Thurgau, parts of the Austrian territory, and annexed them; three years later, they crossed the Alps, and annexed Ticino, and constituted all three subject states. The Swiss were next engaged in a struggle on the French frontier with Charles the Bold of Burgundy. They entered the field with 34,000 men, to oppose an army of 60,000, and yet they were successful, gaining the famous battles of Granson and Morat in 1476. In 1481, the towns of Freiburg and Soleure were admitted into the confederacy. In 1499, the Emperor Maximilian I. made a final attempt to bring S. once more within the bounds of the empire. He sought to draw men and supplies from the inhabitants for his Turkish war; but in vain. He was defeated in six desperate engagements. Basel and Schaffhausen (1501), and Appenzell (1513), were then received into the Confederation, and its true independence began. The abbacy of St Gall, the cities of St Gall, Mühlhausen, and Bienne became associated states, with a vote at the Diet. Geneva, Neufchatel, Valais, and the Grisons, also became associated states, but without a vote.

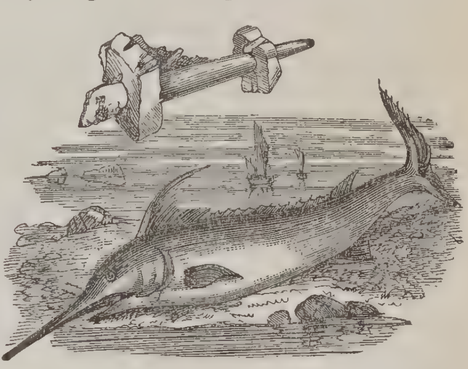
New troubles sprang up with the Reformation. Zwingli began to preach in the beginning of the century; and Zürich, in 1523, adopted his opinions, and was followed by Bern and other cantons of the north. The Forest Cantons remained attached to the Church of Rome. War broke out in 1531, between the Catholics and Protestants, and the former were successful at Cappel, where Zwingli was slain. This victory to some extent settled the boundaries of the two creeds in Eastern Switzerland. In 1536, however, Bern wrested the Pays de Vaud from the Dukes of Savoy, and annexed it to their own territory. In the same year, Calvin settled at Geneva, and the Reformed doctrines spread throughout Western Switzerland. During the Thirty Years' War, Bern, which had become, since the conquest of Vaud, the leading canton, and Zürich, contrived to maintain with great skill the neutrality of S.; and in the treaty of Westphalia, in 1648, it was acknowledged by the great powers as a separate and independent state. At this period, the Swiss, in

immense numbers, were employed as soldiers in foreign service, and the record of their exploits gives ample evidence of their courage and hardihood. Internally, there was great stagnation. The constitution of the larger cantons became more aristocratic, that is to say, the mass of the people lost their power over the governing bodies. In Zürich, Schaffhausen, and Basel, the governing councils were elected by the corporations; and in Bern, Freiburg, Soleure, and Lucerne, a few families had acquired permanent rule. At the end of last century, there was widespread discontent with this state of matters; but the French Revolution broke out, and wars followed, which left no time for its manifestation. In 1798, S. was seized by the French. At the peace of 1815, its independence was again acknowledged. The new Confederation was divided into 22 cantons, each of which was represented in a Diet, which was appointed to hold its annual meetings alternately at Bern, Zürich, and Lucerne. The old abuses which had crept into the constitutions of the cantons were revived, and representation in most of them became based on property qualifications. Officials, the aristocracy, and the clergy joined to oppose innovations, and succeeded in doing so until 1830, when the French revolution broke out. Armed demonstrations were made against the towns, and universal suffrage was generally conceded. Basel town, however, held out; but the difficulty was settled by the separation of the town and country districts—the former remaining conservative, the latter becoming democratic. Geneva and Neufchatel retained their old constitutions. The result of the changes was, however, that ⅔ds of the whole population were allowed to take part in public affairs. The consequences were not what had been expected by the liberals, who found that they had not yet the means of strengthening the central power. In 1839, at Zürich, where Dr Strauss had been appointed a professor of theology, a mob of peasants, headed by the Protestant clergy, overturned the government. In Aargau, a struggle took place between the liberals and the Ultramontane party, which was settled, after long discussion, by an unsatisfactory compromise. In Valais, where universal suffrage had put power into the hands of the reactionary party, a war took place, in which the latter were victorious. They then ruled with a strong hand, and actually forbade the celebration of Protestant worship within the canton. In Lucerne, the headquarters of the Jesuits, the Ultramontane party acted even more extravagantly; they so persecuted their political opponents, that the latter were compelled to leave the canton. These measures caused the greatest discontent. In 1844, a proposal was made in the Diet to expel the Jesuits; but that body declined to act. The radical party then determined to resort to force: they organised bodies of armed men, called the Free Corps, which invaded the Catholic cantons; but they were defeated. Changes favourable to them took place in some of the cantons. The Catholic cantons then formed a league, named the Sonderbund, for defence against the Free Corps. There was a general clamour for its suppression; but in the Diet, only 10½ votes were in favour of that measure. The ruling party in Geneva had been with the majority, and this conduct led to a revolution in that city. One vote was thus gained against the Sonderbund. St Gall added another; and a majority in the Diet, in 1847, declared the illegality of the Sonderbund, and decreed the expulsion of the Jesuits. In the war which ensued between the federal army and the forces of the Sonderbund, the former were victorious at Freiburg and Lucerne. The leagued cantons were made liable in all the expenses of the war, the Jesuits were expelled, and the monasteries were suppressed. An attempt was made by diplomatic notes to intimidate the Swiss government, but the revolution of 1848 broke out, and prevented further interference. In the same year, the radical party, convinced of the necessity of a more powerful central government, carried the constitution of 1848, of which we have already taken notice. Since then, the most important event which has taken place in S. was a rebellion against the king of Prussia, as Prince of Neufchatel. The canton was declared a republic, with a constitution similar to that of the other Swiss states. The king of Prussia protested, but in vain, against the change, and at length he withdrew all opposition, and remained satisfied with the bare title of Prince of Neufchatel, which he still retains.

SWI'VEL is a gun constructed, as regards its carriage, to turn on a pivot, or on two concentric iron rails. Its use is on shipboard or in a fortress.

SWORD, a well-known weapon of war, the introduction of which dates beyond the ken of history. It may be defined as a blade of steel, having one or two edges, set in a hilt, and used with a motion of the whole arm. Damascus and Toledo blades have been brought to such perfection, that the point can be made to touch the hilt and to fly back to its former position. In last century, every gentleman wore a sword; now the use of the weapon is almost confined to purposes of war. In the British army, all officers and sergeants, with troopers of cavalry, wear swords for cutting and thrusting. In the navy, all officers wear similar swords; and the men, in time of action, heavy-backed swords, called *cutlasses*. In the French service, nearly all troops wear a combination of the sword with the bayonet, called a sword-bayonet.—For various sorts of swords and their uses, see RAPIER, CUTLASS, BROADSWORD, SCIMITAR, SABRE, &c.; FENCING.

SWORD-FISH (*Xiphias*), a genus of fishes of the family *Scomberidæ*, having the upper jaw remarkably elongated and compressed, in the form of a sword or dagger. The body is rather of a long shape, and covered with very small scales. There are no teeth. There is one long dorsal fin. There are no finlets. The ventral fins are wanting. The sides of the tail are very strongly keeled. The tail-fin is large and forked. Only one species is known, *X. gladius*, plentiful in the Mediterranean, and in the warmer parts of the Atlantic; sometimes, but rarely, seen on the British coasts. It is bluish black above, and silvery white on the belly, the one colour passing gradually into the other. It is



Sword-fish (*Xiphias gladius*):
With section of a ship's timbers perforated by the sword.

highly esteemed as an article of food, especially when young. It is harpooned by the fishermen of the Mediterranean, and is powerful enough to drag a boat about for many hours after being struck. It has been said to attack the whale with its sword, but this is extremely improbable. Its food consists in great part of squids and cuttle-fish. The use of the sword is unknown. Instances not unfrequently occur of ships' bottoms being perforated by the sword of the S., but there is no good reason to think that an intentional attack is ever made.—Other species of S., belonging to genera closely allied to *Xiphias*, are found in the seas of different parts of the world.

SY'BARIS, and CRO'TŌN or CROTONA, two celebrated Greek colonies in Magna Græcia (q. v.). The former—founded 720 B. C., by Achæans and Trœzenians—was situated in the south of the Lucanian territory, between the rivers Crathis (*Crati*) and Sybaris (*Coscili*), about 3 miles from the Tarentine Gulf; and the latter—founded 710 B. C., by Achæans—about 50 miles south-south-east on the coast of Bruttium. All that is certainly known concerning these cities before the destruction of the former is, that they both rapidly increased in size, wealth, and power, extending their dominions across the peninsula, and founding other colonies, at the same time preserving the most friendly terms with each other. S. is said to have been 6 miles in circumference, and Croton 12 miles; the former being notorious for the excessive and fastidious luxury of its inhabitants (hence the term Sybarite), and the Crotoniates celebrated for the perfection they reached in athletic exercises—the famous athlete, Milo (q. v.), having been a native of Croton. Somewhere between 540—530 B.C., Pythagoras (q. v.) settled at Croton, and exercised very considerable influence over the aristocratic government. About 510 B. C., a democratic leader, Telys, deposed the oligarchy of S., banished 500 of the leading citizens, and assumed the tyranny of the city. The banished citizens having taken refuge in Croton, Telys demanded their surrender, and on being refused, declared war against that city. The Sybarites, with an army said to have amounted to 300,000, met 100,000 Crotoniates, commanded by Milo, at the river Træis, were completely routed, and their city obliterated by the latter changing the course of the Crathis, so as to sweep it away. About 443 B. C., Thurii was founded near the site of Sybaris. After the destruction of S., Croton appears to have gradually declined, suffering much from internal convulsions (see PYTHAGORAS), as well as from the disasters which befell it in its wars with the Locrians, Rhegians (480 B. C.), and Bruttians, and also in those of Dionysius (q. v.) of Syracuse and Pyrrhus (q. v.). Its ruin was completed in the second Punic war; and although, in 194 B. C., it was colonised by Roman citizens, it never again rose to be a place of any importance. Croton, in the time of Herodotus, and at a later period, was famous as a medical school.

The modern town of Cotronē, standing very near the site of the ancient town, has a population of 7168.

SY'CAMINE, a tree mentioned in Scripture, and supposed to be the Black Mulberry (q. v.).

SY'CAMORE, or SYCOMORE (*Sycomŏrus*), a genus of trees of the natural order *Moraceæ*, regarded by many botanists as a mere sub-genus of *Ficus* (see FIG), and differing from the true figs only in the elongated, straight, thickened, and club-shaped stigma. The species are chiefly African, but the geographical range extends also into the west of Asia. Some of them attain a large size and a great age. The EGYPTIAN S. (*S. Antiquorum*, or *Ficus sycamorus*) supposed to be the S. of the Bible, is a large tree, very abundant in Egypt and in some parts of the west of Asia, often planted near villages for the sake of its shade, its wide-spreading head sometimes covering a space of 40 yards in diameter. The figs are

Sycamore (*Acer pseudo-platanus*), shewing leaves, flowers, and fruit.

top-shaped, and grow in clustered racemes on the trunk and oldest branches. They are sweet, well flavoured, and somewhat aromatic. The wood is light, porous, and of little value. It has been supposed that the cases of Egyptian mummies are made of it, but this is disputed. Other species are found in Abyssinia, South Africa, &c.

The sycamore tree of Britain is a species of Maple (q. v.). In some parts of North America, the same name is given to the Plane (q. v.) of that country, *Platanus occidentalis*.

SY'DENHAM, a chapelry in the parish of Lewisham, county of Kent, with a station on the London and Croydon Railway, 8 miles south of London. It has become of world-wide celebrity in connection with the Crystal Palace, which was erected here in 1854, chiefly from the materials of the building of the Great Exhibition (1851). The cost of the erection and appointment of the Crystal Palace amounted to nearly £1,500,000. The building is 1600 feet long, 380 wide, and at the centre transept 200 feet high. The chief arts and sciences illustrated by the collections within the Palace and grounds, are Sculpture, Architecture, Painting and Photography, Mechanics and Manufactures, Botany, Ethnology, Palæontology, Geology, and Hydraulics. There are two concert-rooms, within the larger of which, performances have taken place at which there were 5000 vocalists and instrumentalists. The park and gardens occupy nearly 200 acres, and are adorned with sculptures, stone balustrades, &c., and fountains which are perhaps the finest in the world.

SYDENHAM, THOMAS, a great English physician, was born of good parentage, in 1624, at Winford Eagle, Dorsetshire, and was educated at Magdalen Hall, Oxford. According to the well known French surgeon, Desault, he afterwards studied at Montpellier. He graduated at Oxford as Bachelor in Medicine in 1640. Through the interest of a near relative, he obtained a fellowship of All Souls College, and there continued to prosecute his medical studies. He left the university without

taking a Doctor's degree, which, indeed, he did not obtain till some time afterwards at Cambridge. He settled as a practitioner at Westminster, and practised so successfully that, when only 36 years of age, he already enjoyed the reputation of being one of the first physicians of the period. In his later years, he was much afflicted by gout, which at length carried him off on December 29, 1689. He was buried in St James's Church. S. was not profoundly accomplished as a man of science; even in his own age, deficient as it was in the advanced development to which the researches on which medicine is based have now attained, he was inferior to several of his contemporaries; but in sagacity of observation and accuracy of diagnosis, he was unsurpassed. His skill and his philosophic cast of mind secured him the admiration and friendship of Locke; and his contributions to the literature of his profession received the praise of Haller and Boerhaave. His writings have been often republished both in England and on the continent, the edition entitled *Opera Medica*, which appeared at Geneva in 1716, being the best. Fevers were the department of medicine on which he first bestowed his attention; and before he had been many years in practice, he published, in 1666, his celebrated treatise entitled *Methodus Curandi Febres Propriis Observationibus Superstructa*. This was afterwards reprinted in 1675, with the observations accumulated in the interval. His treatment of the then destructive malady of smallpox was especially felicitous, substituting, as he did, for the stimulating regimen in vogue, the antiphlogistic method of cool air and salines. The most scholarly translation of his works into English is that of Dr R. G. Latham, published in the Sydenham Society's series, to which he gives its name.

SYD'NEY, the capital of New South Wales, and the oldest city in Australia, is situated on the southern shores of Port Jackson, in lat. 32° 52′ S., long. 151° 11′ E. The first party of British settlers that reached New Holland were landed at Botany Bay on January 20, 1788. The spot which they here selected being found ineligible, it was abandoned a few days afterwards, and the infant settlement was transferred to a point about seven miles further to the north, to the place where S. now stands. The choice of the new locality was chiefly determined by the circumstance of a stream of fresh water being found there, flowing into the deep inlet known as Sydney Cove, one of the numberless bays into which the basin of Port Jackson is divided. This last-mentioned magnificent expanse of water, completely land-locked, and admitting vessels of the largest size, extends for some 20 miles inland, ramifying in every direction. Its bold and rocky shores present a succession of picturesque and beautiful landscapes. The cliffs which form the general outline of the harbour often rise to a height of from 200 to 250 feet. In other points, the coast presents a lower level, consisting of a series of terraces and smooth sandy beaches. Perhaps there are few positions on the habitable globe more obviously suitable for the foundation of a great metropolis. Situated at a distance of about 8 miles from the sea, the whole circumference of the bay round which it is built forms a series of natural wharfs, where vessels of 2000 tons burden can be moored within a distance of 20 yards. The narrow entrance of Port Jackson — through what is called the 'Heads' — might easily be made inaccessible to any hostile fleet; whilst the central position of S. makes it necessarily the permanent emporium of the greater number of the British dependencies in the southern hemispheres. The immense coal formation of East Australia extends north and south for some 500 miles, with a breadth of from 80 to 100 miles. S. stands nearly in the centre of this great carboniferous basin; and at various points within a radius of from 30 to 100 miles, large quantities of coal are raised for colonial consumption as well as for export. The sandstone rock upon which the city is erected affords a valuable material for building.

Since the abolition of transportation, the growth of Sydney has been rapid, the population in 186 amounting to 93,596, and in 1881 to 220,427, including the suburbs. For many years, S. enjoyed a complete monopoly of the commerce of these antipodean regions. It has, however, now formidable rivals in Melbourne, Adelaide, and the settlements of Queensland. It must, however, always continue the exclusive outlet for the productions and commerce of extensive pastoral and mineral districts stretching to the north-west, west, and south-west.

The streets in the older parts of the town are narrow and irregular: in the newer portions, care has been taken to avoid these defects; and several of the modern streets, from their breadth and the size and style of the buildings, are not behind those of the principal towns of Europe. The shops, warehouses, and private buildings in George and Pitt Streets present long and compact lines of well-built stone edifices, often assuming a very ornate and ambitious style of architecture. The chief thoroughfares are paved, and lighted with gas, and a system of underground drainage has been carried out at a cost of nearly half a million sterling. There is also an abundant supply of pure water, the source of which is a natural reservoir known as the Botany Swamps.

The *climate* of S. is, upon the whole, temperate and healthy. The chief meteorological conditions during the year 1862 were as follows: The mean temperature for the year, 62·6° Fahr.; for February, 72·1°; for July, 52·5°. The mean maximum for the year, 69·8°; for February, 78·8°; for July, 59·6°. The mean minimum for the year, 55·3°; for January, 65·6°; for July, 45·5°. The rain-fall, 47·09 inches; number of rainy days, 152.

Public Buildings.—By far the most important edifice, not only in S. but in the whole of the Australian settlements, is the university, which stands on a commanding height, and in the centre of a domain of about 150 acres. The principal façade is 500 feet in length, and is flanked at its western end by the Great Hall, the proportions of which are such that, were it in England, it would rank as the third in point of size. Lectures are delivered daily during each term on classics, logic, history, chemistry, natural and experimental philosophy, and jurisprudence. The Museum contains a collection of Greek, Roman, and Egyptian antiquities presented by the former chancellor, Sir C. Nicholson. There are two suffragan colleges in connection with the university—that of St Paul's, belonging to the Church of England; and St John's, erected under the auspices of the Roman Catholic community. The university, erected out of public funds, has a permanent endowment of £5000 a year from the Civil List; and each of the suffragan colleges receives aid towards its building fund, and the stipend of the warden and rector. Eighteen free scholarships, of the annual value of £50 each, are established in the university, in addition to several others that have been founded by private benefactors. The university is incorporated under an act of the Colonial Legislature and by royal charter. It is only empowered, however, to confer degrees in arts, law, and medicine; and, so far as the university is concerned, instruction is limited to

purely secular teaching. The religious training of the pupils is left to the affiliated colleges. The metropolitan cathedral of St Andrew has been 50 years in the course of erection, and is still unfinished. Its style is that of the later perpendicular. Many of the churches, upwards of 60 in number, belonging to different religious denominations, are tastefully designed. Amongst the buildings devoted to secular purposes, the most imposing and effective, in point of size and architectural design, are the residence of the governor, the museum of natural history, the exchange, the custom-house, and the public grammar-school. The neighbourhood of S., with every nook in the adjacent bays, is studded with elegant villas and snug cottages, surrounded by their park-like grounds, and gardens of orange-trees, bananas, and numberless semi-tropical plants unfamiliar to the English eye of the newly-arrived immigrant. Several manufactories have been established in S.; but the gold discovery has hitherto arrested their progress or altogether destroyed them. S. has two theatres, several mechanics' institutes, a large hospital for the sick, an orphan asylum, and various other charitable and benevolent institutions, all of which are liberally endowed and supported by public grants or private munificence.

SYE'NE. See Assouan.

SY'ENITE, a granitic rock found near the city of Syene, in Egypt. It is composed of quartz, felspar, and hornblende, and differs from true granite in having the mica replaced by hornblende. The felspar is generally red (sometimes it is found of a white colour), and the hornblende gives a mottled red and dark green colour to the rock.

SY'LLABUB, a culinary preparation, formerly much more used than at present. It consists of sugar and cream flavoured with brandy, sherry, and lemon rind and juice, worked into a froth, and served up in that state in glasses.

SY'LLOGISM, a name expressing a principal branch or department of Logic. When we reason, or get at truth by means of inference, we are said to proceed either inductively (see Induction) or deductively. Deductive reasoning, when fully and methodically expressed, takes the form called the syllogism. 'This thing will sink in water, for it is a stone,' is a deductive argument, but not fully stated; the complete form is: 'Stones sink in water; this is a stone; therefore, this will sink in water'—which form is called a syllogism.

To a perfect syllogism it is necessary that there should be three, and no more than three, *propositions* (see Proposition); these are the conclusion, or the matter to be proved, and two others that are the means of proving it, called the premises. It is also necessary that there should be three, and no more than three, *terms*, namely, the subject and the predicate of the conclusion, and one, called the middle term, which must occur in both premises, being the connecting link for bringing the two other terms together in the conclusion. The *predicate* of the conclusion is called the major term, because it is in its scope the largest of the three; the *subject* of the conclusion is the minor term, as being the smallest in scope. The three terms enter into the premises in this manner: the major term and middle term make one premise, called the major premise; the middle term and the minor term make the minor premise. In the syllogism above stated, the terms are, 'a thing that will sink in water' (major), 'this thing' (minor), 'stone' (middle); the premises are, 'stones sink in water' (major), 'this thing is a stone' (minor); the conclusion is, 'this thing will sink in water.'

The form now given, although the regular and fundamental form to prove any affirmative conclusion, is not the only form that an argument may assume. The totality of syllogistic forms is divided into *figures*, and each figure into *moods*, which are the distinct syllogistic forms; the principle of division being as follows. The figure is determined by the position of the middle term; which may be the *subject* of the major premise, and the *predicate* of the minor (1st figure), the *predicate* in both (2d figure), the *subject* in both (3d figure), the *predicate* of the major and the *subject* of the minor (4th figure).

The word 'figure' is borrowed from rhetoric, where it means a departure from plain and ordinary speaking, as metaphor, hyperbole, &c. But, as remarked by Hamilton, only the last three of the foregoing enumeration should be called 'figures.' The first should be considered as embracing the regular forms of reasoning, and the others as properly figures—that is, forms more or less inverted, irregular, or unnatural, although still correctly representing reasonings that actually occur. These forms may be all *reduced* to forms in the 1st figure; their inversions or distortions being, as Hamilton would say, *redressed*, or restored to the primitive and fundamental type, namely, the syllogisms of the 1st figure.

The 4th figure did not belong to the original scheme of Aristotle, and it is usually considered as both unnatural and unnecessary, being only an awkward inversion of the first. There would then be the natural or standard syllogisms (the 1st fig.), and two sets of figurative departures from them (2d and 3d figs.).

The syllogisms of each figure are said to differ in *mood*, or according to the *quality* and the *quantity* of the propositions—that is, according as these are affirmative or negative (quality), universal or particular (quantity).

The entire scheme may be presented as follows: The symbols used are P (predicate of conclusion), major term; S (subject of conclusion), minor term; M, middle term. The general type of the first figure or standard is:

M is P.
S is M.
S is P.

When the quality and the quantity of the propositions are expressed, there arise four syllogisms of this form—two affirmative, and two negative:

$$\left.\begin{array}{l}\text{All M are P.}\\ \text{All (or some) S are M.}\\ \text{All (or some) S are P.}\end{array}\right\}\ \textit{Barbara, Darii}$$

All matter gravitates.
All (or some) air is matter.
All (or some) air gravitates.

$$\left.\begin{array}{l}\text{No M is P.}\\ \text{All (or some) S is M.}\\ \text{No S is P; some S is not P.}\end{array}\right\}\ \begin{array}{c}\textit{Celarent}\\ \text{and}\\ \textit{Ferio.}\end{array}$$

No matter is destructible.
All (or some) air is matter.
No air is destructible; some air is not destructible.

The general scheme of the 2d *figure* is:

P is M.
S is M.
S is P.

There are four syllogisms in all, which we may take in pairs thus:

$$\left.\begin{array}{l}\text{No P is M.}\\ \text{All (or some) S are M.}\\ \text{No S is P; some S are not P.}\end{array}\right\}\ \begin{array}{c}\textit{Cesare}\\ \text{and}\\ \textit{Festino.}\end{array}$$

'No destructible thing is matter,' &c., as in the last form.

All P is M.
No S is M; some S is not M. — *Camestres* and *Baroko.*
No S is P; some S is not P.

In this figure, there is a certain distortion of the previous or regular figure. In the first of the two pairs, the major is, No P is M, instead of the equivalent (1st figure), No M is P. In the first form of the second pair, the minor is, No S is M, instead of the equivalent, No M is S, which should be the major to be regular; the amended premises would then give, in conclusion, No P is S, equal to No S is P.

All matter is extended.
No mind is extended. — *Camestres.*
No mind is matter.

The last form, with a particular conclusion, is exemplified thus:

All matter is extended.
Some things are not extended.
Some things are not matter.

This is a form technically called *Baroko*, which is one of two that are especially difficult to reduce to the standard forms.

This figure proves only negatives.

The scheme of premises in the 3d *figure* is

M. P.
M. S.

Six varieties of syllogism come under this figure; we may arrange them in three pairs, the first two pairs having the same major, and the third the same minor:

All M is P.
All (or some) M is S. — *Darapti* and *Datisi.*
Some S is P.

All planets move.
All (or some) planets are heavenly bodies.
Some heavenly bodies move.

No M is P.
All (or some) M is S. — *Felapton* and *Ferison.*
Some S is not P.

No solid body is perfectly transparent.
All solid bodies gravitate.
Some gravitating things are not perfectly transparent.

Some M is P; some M is not P.
All M is S. — *Disamis* and *Bokardo.*
Some S is P; some S is not P.

The first of the two is merely a standard syllogism (Darii), with transposed premises; the second (Bokardo) is more complicated, as in the example:

Some men are not fit to rule.
But all men are liable to have dominion.
Some men, liable to have dominion, are not fit to rule.

In the 4*th figure*,

P is M,
M is S,

there are five syllogisms. The mere forms are enough to quote.

All P are M.
All M are S. — *Bramantip.*
Some S are P.

All P are M.
No M is S. — *Camenes.*
No S is P.

Some P are M.
All M are S. — *Dimaris.*
Some S are P.

No P is M.
All M are S. — *Fesapo.*
Some S are not P.

No P is M.
Some M are S. — *Fresison.*
Some S are not P.

The reasons why these syllogisms are true, and why no other of 256 possible combinations of propositions can give true conclusions, are certain laws, called the rules of the syllogism, which repose on first principles of the highest certainty.

Mr Mill has laid down the following fundamental axioms of the syllogism, as stated in its standard forms in the 1st figure. (1.) 'Attributes coinciding with the same attribute, coincide with one another.' M, the middle term, coincides with P, the predicate; S, the subject, coincides with M; therefore S and P coincide with one another. (2.) 'Any attribute incompatible with a second attribute, is incompatible with whatever that second attribute coincides with.' No M is P; M is incompatible with P; but S coincides with M, and therefore it also is incompatible with P.

All the syllogisms of the last three figures are reducible to the first, by conversion of propositions and transposition of premises, according to the nature of the case. The symbolic name of each syllogism contains instruction for this process, as well as stating the composition of the syllogism. To aid the memory, these symbols are put together in five Latin hexameter verses of very ancient but unknown origin:

'Barbara, Celarent, Darii, Ferioque prioris.
Cesare, Camestres, Festino, Baroko, secundæ.
Tertia Darapti, Disamis, Datisi, Felapton,
Bokardo, Ferison habet, quarta insuper addit
Bramantip, Camenes, Dimaris, Fesapo, Fresison.'

The first line gives the standard figure, and states the propositions entering into each syllogism. The three A's in Barbara are three universal propositions. The E, A, E, in Celarent, are a universal negative, a universal affirmative, a universal negative; in Darii, A, I, I, a universal affirmative and two particular affirmatives, &c. In the other figures the commencing letter (C, B, &c.) shews which standard syllogism each is to be reduced to (Baroko to Barbara, Cesare to Celarent, &c.). The consonant *s* means simple conversion of the proposition marked by the preceding vowel; *p* means conversion by limitation, or *per accidens; m* signifies the transposition of the premises; *k* occurs in Baroko and Bokardo, and denotes that these are to be reduced by supposing the conclusion false, and then shewing that on that supposition Barbara would be contradicted—from which it is inferred that the original form is true.

There are some species of deductive arguments that do not fall under the syllogistic figures. Thus, the major may state a conditional proposition, and the minor affirm the truth of the condition. 'If the witness is to be believed, the man is guilty' (major); now 'the witness is to be believed' (minor); therefore 'the man is guilty.' A true conclusion would also be obtained by a minor denying the consequent, 'the man is not guilty.' It would then follow that the witness (who affirms his guilt) is not to be believed. But no conclusion would follow from either denying the condition, 'the witness is not to be believed,' or affirming the consequent, 'the man is guilty;' for, in the first place, the man might be guilty whether this particular witness be credible or not; and secondly, the guilt of the man does not prove the credibility of the witness. This is called the *Conditional* Syllogism.

Again, the major may be what is called a Disjunctive or Alternative Proposition, from which also inferences may be drawn by supplying certain minors. 'This was done by either A or B;' now 'it was not done by A (or by B);' therefore 'it was done by B (or by A).' Should the major be understood to mean that it was done by one, and not by both, there would be two other possible inferences. 'It was done by A (or by B);' therefore 'it was not done by B (or by A).' There are other disjunctive pairs, as for example: 'Either A is B, or C is D;' now 'A is not B, therefore C is D,' &c. This is called the *Disjunctive* Syllogism.

A combination of the Conditional and the Disjunctive makes the *Dilemma*. For example:

> If A exist, then either B or C exists.
> Neither B nor C exists.
> Therefore A does not exist.

The following dilemma was given to refute the practice of torturing witnesses: 'A person able to endure pain will be likely to utter falsehood under torture; one unable will be equally likely; therefore, a person under torture will be likely to utter falsehood.'

A very great enlargement has been given to the doctrine of the syllogism, by Sir W. Hamilton (see QUANTIFICATION), Professor De Morgan, and the late Professor Boole of Cork. They have shewn that many more syllogistic pairs can be created, and have invented symbols for the purpose. It is, however, comparatively few, either of the old pairs or of the new, that are assumed by the ordinarily occurring arguments, either in the sciences or in common affairs. By far the most useful part of the syllogism is contained within the limits of the 1st or standard figure, which shews what premises are to be looked out for to prove any conclusion; namely, some *general assertion* of matter of fact, affirmative or negative (major), and a *particular assertion* that a given thing comes under the subject of the general assertion (minor), and therefore falls likewise under its predicate. When an argument is stated in a puzzling or perplexed form, with perhaps the omission of one of its essential propositions, it is well to know how to supply the suppressed premises, and put the argument into regular order: the truth or fallacy of the reasoning then becomes evident at a glance.

SYLPHS, in the fantastic system of the Paracelsists, are the elemental spirits of the air, who, like the other Elemental Spirits (q. v.), hold an intermediate place between immaterial and material beings. They eat, drink, speak, move about, beget children, and are subject to infirmities like men; but, on the other hand, they resemble spirits in being more nimble and swift in their motions, while their bodies are more diaphanous than those of the human race. They also surpass the latter in their knowledge, both of the present and the future, but have no soul; and when they die, nothing is left. In form they are ruder, taller, and stronger than men; but stand nearest to them of all the elemental spirits, in consequence of which they occasionally hold intercourse with human creatures, being especially fond of children, and of simple harmless people; they even marry with our race, like the Undines and the Gnomes, and the children of such a union have souls, and belong to the human race.

In common usage, the term sylph has a feminine signification, and is applied to a graceful maiden. How this curious change of meaning occurred, is not quite certain; but it is probably owing to the popularity of Pope's *Rape of the Lock*, which introduced the term into the world of fashion and literature. For although even in Pope, the sylph that guards Belinda is a *he*, yet the poet so refined and etherialised his spiritual agents, that they soon came to be associated with all our ideas of feminine grace and beauty; and this circumstance may have reacted on the popular idea—always loose and inaccurate—of their character and sex, and brought about the change of gender to which we have alluded. See Paracelsus's *Liber de Nymphis, Sylphis, Pygmæis et Salamandris et Cœteris Spiritibus* (Basel ed. of Paracelsus's works, 1590).

SYLVESTER, the name of two popes, and of a third who was an anti-pope. The pontificate of the first immediately succeeded that of Melchiades in 314, and is memorable for the great council of Nicæa, in which the heresy of Arius was condemned. S. himself did not attend the council, but sent two priests—Vitus and Vincentius—to take his place. His name is also celebrated in connection with the so-called donation of Constantine to the Roman Church, the spuriousness of which (although no doubt had been raised regarding it during many centuries) has long been admitted by critics. He died in 335.—Sylvester II., one of the most learned of the medieval popes, originally called Gerbert, was born at Aurillac, in Auvergne, early in the 10th century. He was educated in the monastery of his native village; but went early to Spain, where he learned mathematics, and afterwards to Rome. He was appointed abbot of the monastery of Bobbio, where he taught with much distinction and success. At a later period he went to Germany as preceptor of the young Prince Otho, afterwards Otho II.; and ultimately became secretary to the Archbishop of Rheims, and director of the cathedral school, which became eminent under his care. The archbishop having been deposed, S. was elected to the archbishopric; but he was afterwards set aside, the deposition of his predecessor having been declared invalid. In the year 998, however, he was appointed Archbishop of Ravenna, whence he was called to the pontifical throne, in the following year, under the name of Sylvester II. He was a man of rare acquirements for his age. He was an adept in mathematics, and in practical mechanics and astronomy, in which department his attainments acquired for him among his contemporaries the evil reputation of a magician. He is also believed to have been acquainted with Greek, and perhaps with Arabic. Of all his works, which were numerous, his letters (printed by Du Chesne in the *Historians of France*) have attracted most notice from their bearing on the history of an obscure period.

SYLVESTER, JOSHUA, was born in 1563. His life was divided between the somewhat incongruous pursuits of merchandise and poetry, in neither of which did he achieve a distinct success. Of his original works, the human memory retains no trace; but in virtue of the great, though fleeting popularity obtained by his English version of the *Creation* of Du Bartas, from which Milton is thought to have derived some hints, he lives in literary history as a sort of *nominis umbra*. He led a somewhat wandering life, and died at Middleburg, in Holland, in the year 1618.

SYLVI'ADÆ, a family of birds, of the order *Insessores*, and tribe *Dentirostres*, including a very great number of small species, among which are many of the birds most noted for sweetness of song, whilst something of this power is possessed by almost all the family, so that the name *Warblers* is often used as synonymous with Sylviadæ. The bill is sharp, slender, straight, and rather compressed towards the tip; the wings moderately long; the legs slender. To this family belong the Nightingale, the Blackcap, numerous species known by the name

or Warbler, the Redbreast, Redstart, Wheatear, Whitethroat, Stonechat, Whinchat, Golden-crested Wren, Hedge-sparrow, &c. The S. are diffused over all parts of the globe; and some of those found in tropical countries possess considerable musical powers, but are generally as silent during the great heat of the day as during the darkness of night, and are chiefly to be heard early in the morning.

SYMBO'LIC BOOKS, in the language of the church, is a phrase that signifies the same as Creeds and Confessions (q. v.). The name is derived from the Greek *symbolon*, a sign or mark by which anything is known—a creed being the distinctive mark of a religious community.

SYME, JAMES. See SUPPLEMENT in Vol. X.

SYMMACHUS, Q. AURELIUS, a distinguished Roman orator, scholar, and statesman who flourished towards the close of the 4th c., was educated in Gaul, and after holding several lesser offices, became prefect of Rome (384 A.D.). Seven years later he was raised to the consulship. The date of his death is unknown, but we know that he was alive in 404 A.D. The character of S. is a very fine one. A sincere pagan in an age when classic paganism was almost extinct, he proved in his own person a pattern of its choicest virtues, and manfully, if in vain, strove to regain for it a place of honour in the state. S.'s extant writings consist of ten books of letters (*Epistolarum Libri X.*) and the fragments of nine orations. The former were published after his death by his son, and contain not a little that is valuable in relation to the history of the period; but the style is in general a slavish imitation of Livy. The best editions of the Epistolæ are those of Juretus (Par. 1604) and Scioppius (Mainz, 1608). The fragments of the orations were first discovered by Cardinal Mai in a palimpsest of the Ambrosian Library, and were first published at Milan in 1815; afterwards, with some additions, at Rome in 1823, in *Scriptorum Veterum Nova Collectio.* See Morin's *Etude sur la Vie et les Ecrits de Symmaque, Préfet de Rome* (Par. 1847).

SY'MMETRY OF ORGANS. Throughout the animal kingdom, a symmetry of organs very generally prevails in the two sides of the body. This is the case in man and in all the *Vertebrata;* more perfectly, however, in the external than the internal organs, the two sides of the body presenting great diversities in the circulating, digestive, and other systems. Even the external organs, although similar on the two sides, are never perfectly so. On comparing the two hands, for example, the veins of the one will be seen to differ from those of the other. In *Mollusca*, the symmetry of the two sides sometimes exists, and is sometimes entirely lost, the one side remaining undeveloped in the growth of the animal. In the *Articulata*, the symmetry is in general as perfect as in the *Vertebrata*, and in the internal structure even more so. In the *Radiata*, the whole type is very different, and a very different kind of symmetry appears, not with reference to two sides, but to the rays into which the body divides.

In the vegetable kingdom, a symmetry is found, more or less perfect, but never completely so, between the two sides of leaves, fronds, &c. In flowers, a symmetry appears in the regular distribution of sepals, petals, stamens, &c., around the centre of the flower; and even those flowers which least exhibit it when fully blown, as papilionaceous flowers, possess it in the early stages of the bud as perfectly as others.

SYMPATHE'TIC INK. See INK.

SY'MPATHY (Gr. *sympătheia*, fellow-feeling) may be defined as the assumption by different individuals, or by different parts of the same individual, of the same or an analogous physiological or pathological state at the same time or in rapid succession. The late Dr Todd (art. 'Sympathy' in the *Cyclopædia of Anatomy and Physiology*) divides all the examples of sympathy which are included in the above definition into three classes; first, sympathies between different individuals; secondly, those which affect the mind, and, through it, the body; and, thirdly, those which are strictly organic, and therefore physical.

As examples of the *first class* may be mentioned the readiness with which the act of yawning is induced in a company, if a single person begins to yawn; the facility with which hysterical convulsions are induced in a female hospital ward by a single case; the fascination of its prey by the serpent, apparently by the power of the eyes; the similar power exerted by so-called electro-biologists and mesmerists, and by which some men can control even the fiercest carnivora. Of these sympathies the only explanation that can be given is that suggested in the article on ANIMAL MAGNETISM (q. v.). As examples of the *second class*, the following cases may be adduced. Certain odours—as of strawberries, mutton, cats, and other most diverse objects—will induce fainting in some people; the smell of a savoury dish will excite a flow of saliva in the mouth of a hungry person; and the excitement of the emotions of pity will produce a copious flow of tears. In these cases, an affection of the mind is a necessary link, but why that affection of the mind should produce its peculiar effect, is a question not easily answered; but it is plain that the portion of the nervous centre which is affected in such cases, must have a direct influence upon the parts in which the sympathetic phenomena appear, through commissural (or connecting) fibres, or the continuity of its gray matter with that of the centre from which its nerves immediately spring. Examples of the *third class* occur in the pain in the knee which arises from disease of the hip-joint; the pain in the right shoulder from disease of the liver; the pain over the brow on taking a draught of iced water into the stomach; the various spasmodic affections connected with intestinal irritation, or the irritation of teething; the vomiting that occurs on the passage of a biliary or renal calculus, &c. All these cases may be more or less satisfactorily explained by the known laws of the sensory and motor nerves. In some of these cases the explanation, however, cannot be regarded as altogether complete. For example, the pain over the brow from the ingestion of cold water or ice into the stomach, may be referred to irritation of the gastric branches of the pneumogastric nerves communicated in the medulla oblongata to the fifth nerve; but why the irritation should be confined to the frontal branch of the first (or ophthalmic) division of the fifth nerve, we are utterly unable to explain.

SY'MPHONY, in Music, a word used in two different senses: 1. The instrumental introduction and termination of a vocal composition, sometimes called *ritornello;* 2. A composition for a full orchestra, consisting of from three to six movements. It is for the orchestra what a Sonata (q. v.) is for a single instrument; but generally of greater length, and its movements more fully and richly developed, the subjects introduced being worked out in broader masses. The most usual though not unvarying order of movements is a brilliant allegro, ushered in by a slow introduction, an adagio or andante, a minuet with its trio, a short sportive movement called a scherzo, and a lively finale. The symphony is one of the highest of musical compositions, and one in which excellence is rare. Haydn, Mozart, Beethoven, and Mendelssohn are among the few successful composers of symphony; and the nine symphonies of Beethoven are generally acknowledged

to be the greatest works of their class. The Overture (q. v.) is in form not unlike a symphony, but much shorter; but the terms symphony and overture were at one time used almost synonymously, and several of Haydn's early symphonies are called overtures. At the present day the overture in the composer's score of an Italian opera is called *Sinfonia*.

SY'MPHYTUM. See COMFREY.

SY'MPTOMS (Gr. *sympiptein*, to concur), in Medicine, are the morbid phenomena by which the physician becomes aware that derangements of some kind have taken place in the economy; but it requires a mental effort to convert these symptoms into signs of disease. A symptom thus converted into a sign of some special disease or disordered condition, tends to constitute the *diagnosis*, or recognition of the disease. 'The interpretation of symptoms,' as Dr Aitken observes, 'can only be successful after a close observation of the patient—often prolonged and repeated for more complete investigation—so as to connect the results arrived at with his previous history. The utmost logical acumen is required for the due interpretation of symptoms. The individual value of each ought to be duly weighed; one symptom must be compared with another, and each with all, while the liability to variation of a similar symptom in different cases of a like kind must not be forgotten. Thus only can the nature of a disease be clearly determined, its severity and dangers fully appreciated, its treatment indicated, and the probability of recovery foretold.'—*The Science and Practice of Medicine*, 3d ed., vol. i., p. 9. Many writers, following the example of Laennec, confine the term *symptom* to the phenomena depending on vital properties; while those phenomena of disease which are more directly physical, they call *signs*. We thus have what may be called *physical signs* and *vital symptoms*. The form, size, colour, firmness or softness, heat and odour of a part of the body, the sounds which it yields on percussion or discultation, &c., afford *physical signs;* while *vital symptoms* may be exemplified in pain, uneasiness, altered or impaired sensations, spasm, vomiting, the accelerated pulse and hot skin of fever, the state of the tongue and of the alvine and urinary excretions, &c. The term *semeiology* (literally, *the theory of signs*) has been given by medical writers to the general study of this subject, which is admirably discussed in Williams's *Principles of Medicine*.

SY'NAGOGUE (Gr. = *ecclesia;* Heb. *beth-hakkeneseth*, house of assembly), a Jewish place of worship. The origin of this institution is probably to be traced to the period of the Babylonian captivity, although tradition finds it in the patriarchal times. When, at the time of Ezra, and chiefly through Ezra's instrumentality, the ancient order of things was re-established in Judea, synagogues were established in all the towns for the benefit of those who could not take part oftener than three times a year, or not even as often as that, in the worship of the temple at Jerusalem, and a special ritual of lectures and prayers was instituted. From the time of the Maccabees, we find them even in all the villages; and Josephus, Philo, the New Testament, the Mishna, and the Talmud, constantly allude to them. Common prayer and religious instruction were the purpose for which the people there met. The Sabbaths and feast-days were the principal times on which the faithful assembled in them; and they contributed more than anything else to the steadfast adherence of the people to their religion and liberty as long as there was any possibility of keeping both intact. At the same time, they gradually undermined the priestly and aristocratic element that gathered round the temple, its gorgeous worship and kingly revenues. Little is known of any special laws respecting the construction of these buildings, save that the faces of the worshippers should be directed towards Jerusalem (*misrach* = eastwards) (see MOSQUE); or that, in accordance with a verse in the Psalms, there should be a slight descent of a step or two on entering it, or that it should stand, if feasible, on a slightly elevated ground, or be somehow or other made visible far off. Erected out of the common funds or free gifts of the community, it had also to be supported by taxes and donations. All profane doings were strictly prohibited in it. No eating, drinking, reckoning, and the like, were allowed; and even as to dress and other things of general decorum, the reverence due to the place was enforced as rigidly as possible. It represented in miniature the form of the temple, itself an enlarged type of the tabernacle. At the extreme eastern end was the *Aron hakkodesh*, the holy ark, containing several copies of the Pentateuch, from which the periodical readings were chanted. In front of this was the stand of the public reader of the prayers, not far from which was suspended the everlasting lamp (*ner tamid*). On a raised platform in the middle of the synagogue, was the place of the reader or preacher. The women sat separated from the men by a low partition five or six feet high. The affairs of the synagogue were administered by a board of 'ancients' or 'elders,' at whose head stood a chief or principal (*Rosh hakkeneseth* = *archisynagogos*). This college managed the inner affairs of the synagogue, and had even the power of excommunication. The officiating minister, whose office it was to recite the prayers aloud, was called *sheliach tzibbur*—messenger of the community (*angelos ecclesias*, Rev.). His qualifications were, among others, to be active, to be father of a family, not to be rich or engaged in business, to possess a good voice, to be apt to teach, &c. The beadle, or *chazzan*, had the general charge of the sacred place, and its books and implements. He had to present the scroll to the reader, and assist on other occasions. During the week-days, he had to teach the children of the town or village. He too had to be initiated by a solemn imposition of hands. This name of chazzan, however, at a later period, came to designate the officiating minister, and it has retained that meaning until this day. Almoners or deacons, who collected and distributed the alms, possibly the same as the *Batlanim* or 'idle men,' whose office in relation to the synagogue cannot be exactly determined now, but who had always to be ready for the purpose of making up the requisite number of *ten* worshippers, were further attached to the general body of officials. Respecting the prayers used, we have spoken under LITURGY (JEWISH). As to the time of daily worship, we may observe that the third, sixth, and ninth hours of the day were the times appointed for it, and the more special days were the Monday and Thursday, when the judges sat, and the villagers came to town; and the Saturday, on which the forms of some of the prayers were altered according to the occasion.

On the connection between the Jewish synagogue and the Christian church, and their respective rites and modes of worship, we cannot here enlarge. Thus much, however, we may say, that it is obvious to the most superficial observation that the principal practices of the latter belong, with certain modifications, to the former; and it has been conjectured that even the melodies of certain hymns still sung in the Roman churches are to be traced to the temple and the synagogues. It is, moreover, well known that the early Christian churches were entirely organised after the pattern of the synagogues. As to the judicial

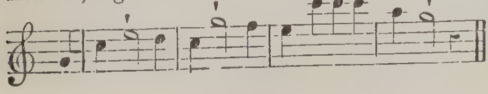
power exercised by the officers of the synagogue, we refer to SANHEDRIM. They had, there can hardly be a doubt, a kind of authority with regard to religious transgressions; but how far they were allowed to carry this authority, is not so easily determined. Modern synagogues differ but in some minor points—additional prayers and the like—from what we gather to have been the nature of those at the time of Christ, save that there are no more elders, but a simple board elected from the community, without any authority beyond that of, perhaps, a board of churchwardens, and that the chazzan, as we said, has now the functions of the 'sheliach.' See JEWS, TEMPLE, LITURGY (JEWISH), &c. The languages used in the early synagogues of Palestine and Alexandria, were Hebrew, Aramaic, and Greek respectively.

SY'NAGOGUE, THE GREAT (*keneseth haggedolah*), an assembly or synod, supposed to have been founded and presided over by Ezra, consisting of 120 men, said to have been engaged in remodelling the national and religious institutions of the Jews after the return from Babylon. The palpable chronological discrepancies that occur in the early accounts about this synod, together with other doubtful points, have led modern scholars to deny its existence completely. But the fact of Josephus not mentioning it avails very little against the positive assertions of the Talmud, and what is still more important, of the Karaites, the professed adversaries of all tradition. True, Ezra, the contemporary of Artaxerxes, can never have taken his place in it together with Zerubbabel and Joshua, who left Babylon under Cyrus, or with Simeon the Just, who lived at the time of Alexander the Great. These, however, are but apparent anachronisms. The tradition never meant anything else than that the institution founded by Ezra, and which lasted up to the time of Alexander, comprised 120 men, of whom Simeon was one of the last. Anyhow, there is absolutely no reason to doubt that Ezra and Nehemiah did a certain amount of work which they could not have done without being assisted by eminent collaborators. It was this body to which certain vital ameliorations in the administration of justice are ascribed. They developed public instruction, and fixed and enlarged the Mosaic laws by certain rules of interpretation. 'Be circumspect in judgment; make many disciples; and erect a fence around the law;' are some of the principal sayings ascribed to them. Above all, it seems to have been the office of Ezra and his coadjutors—the men of the Great Synagogue—to collect, purify, and redact the sacred books as much as in them lay. Whether, however, they really introduced the vowel-points, which have been handed down to us by the Masoretes, instituted the Feast of Purim, sanctioned the Eighteen Benedictions (see LITURGY, JEWISH), &c., is more than doubtful. They certainly disappeared before the Sanhedrim (q. v.) were instituted, but it may be that their legislative functions were no longer needed at that advanced period.

SYNA'NTHERÆ. See COMPOSITÆ.

SYNCLI'NAL AXIS is the line of curve in the trough of a series of beds from which the strata rise on either side. The ridge-curve is called the anteclinal axis.

SYNCOPA'TION, in Music. Notes which begin on the unaccented part of a measure, and end on the accented, are called syncopated or driving notes. Their effect is to invert the rhythm, and lay an emphasis on the usually unaccented part of the measure, e. g.:



SY'NCOPÉ. See FAINTING.

SY'NDIC (Gr. *syn*, with, and *diké*, justice), a name which has at different times and in different countries been given to various municipal and other officers. In Geneva, the chief magistrate was formerly called the syndic. The syndics of cities in France, under the old régime, were officers delegated by the municipality as agents or mandatories; the various trading companies in Paris and the university had also their syndics; and in the university of Cambridge the same name is applied to members of special committees of members of the senate, appointed by grace from time to time for specific duties. See UNIVERSITY.

SYNE'CDOCHÉ (Gr. literally an 'understanding one thing with another') is a term in rhetoric denoting that mode of expression by which a part is put for the whole, and *vice versâ;* as e. g., a door for a house, a sword for any weapon of war.

SYNE'RGISM (Gr. *synergeo*, to work together with), the name given to a doctrine of theology which teaches that in the work of conversion, the will of man is not wholly passive, but can co-operate, through consent, with the Divine Spirit. About 1557, the question was hotly discussed by the Protestant theologians, Pfeffinger, Flacius, and Strigel, and soon the whole theological world was wrangling over the point. The Wittenberg divines were in favour of, the Mansfeld divines against, synergism. Finally, the *Concordien formel*, in its third article, condemned it.

SYNGE'NESIA. See COMPOSITÆ.

SYNGNA'THIDÆ. See PIPE-FISH.

SY'NOD (Gr. and Lat., an assembly) in general signifies a meeting, but it is almost exclusively applied to ecclesiastical assemblies for the purpose of deliberating on doctrinal or disciplinary subjects. In church law, several kinds of synods—called also Councils (q. v.)—are enumerated: (1) ecumenical or general, of the entire church; (2) national—that is, of the church of an entire nation; (3) provincial—that is, of a province; (4) diocesan, or of a single diocese. Of these, the ecumenical council has been already described. Of the others, little explanation is needed beyond what is conveyed in the names themselves. By the law of the Roman Catholic Church, the decrees of a national or provincial synod must be submitted to the pope, and unless confirmed by him, or at least suffered to pass for two years without condemnation, are not held to have force. The diocesan synod is convened by the bishop, and consists of the members of the chapter, the beneficed clergy having the permanent care of souls, and the heads of the communities of regular clergy. Synods of the English Church are only held by the authority of the crown. A Presbyterian synod consists of only the ministers and elders within the particular district, generally one elder for each congregation. It is subordinate, however, to the General Assembly, when there is a General Assembly.

SYNO'DIC, the epithet applied to the period which elapses between a planet's appearance at one of the nodes of its orbit, and its return to the same node. See NODES and MONTH.

SY'NONYM. When any one of several words will serve to name or express the same thing, that thing is said to be *polyonymous*, or many-named, and the words are called *synonyms* (Gr. names together, or in company). In this wide sense, *man*, *soldier*, *general*, *Frenchman*, might be called synonyms, as they can all be applied to denote the same individual—e. g., Napoleon. See NOUN. But the term is commonly applied in a restricted sense to words having substantially the same meaning.

with only slight shades of difference—as *observe* and *remark*. In a settled and matured language, no two words can have exactly the same meaning; in such a case, one of them would be superfluous, and would be silently dropped. Words that were originally identical in application, have become differentiated by usage, each being appropriated to a special variety of the general notion.

The English language abounds in pairs of synonyms like *sharp* and *acute*, of which the one is Anglo-Saxon, the other borrowed from the Latin. It would be difficult to find a case of more exact correspondence of sense than *acutus* in Latin, and *sharp* (Ger. *scharf*) in Teutonic; but *acute* in English has become confined to the metaphorical sense of sharpness of the intellect or of the senses, the only case of its retaining the primary, physical signification being in the technical phrase, an 'acute angle.' *Sharp*, again, is applied both in the physical sense and also in the metaphorical; but metaphorical *sharpness* is not exactly the same thing as *acuteness*. A 'sharp' lad is one quick in apprehension and movement; an 'acute' intellect is one having great power of penetration and discrimination; while in a lawyer of 'sharp' practice, a reprehensible moral quality is implied.

SYNO'VIAL MEMBRANES AND FLUID. In every joint in which a considerable range of motion is required, the osseous segments (or contiguous extremities of bones) are separated by a space, which is called the cavity of the joint. The end of each of the bones entering into the composition of the joint is incrusted by a layer of articular cartilage adapted to its form, and the entire cavity of the joint is lined by a delicate membrane, which is termed the *synovial membrane*, which secretes a peculiar viscid matter, termed *synovia*, or *synovial fluid*, for the purpose of lubricating the inner surface. In its microscopical characters, a synovial membrane so closely resembles a serous membrane, that we shall content ourselves with referring the reader to the article on the latter structures. There are, however, certain points of difference, which are fully described in the article 'Serous and Synovial Membranes' in *The Cyclopædia of Anatomy and Physiology*. Like a serous membrane, a synovial membrane is always a closed bag, like the pleuræ, for example, with an attached and a free surface, the latter being smooth and moist. A very simple form of synovial membrane—anatomically known as a *bursa*—is employed to facilitate the gliding of a tendon of a muscle or of the integument over a projection of bone. It consists of a bag connected by areolar tissue with the neighbouring parts, and secreting a fluid in its interior. These bags are sometimes prolonged into *synovial sheaths*, which surround long tendons, such as those of the flexor and extensor muscles of the fingers and toes. In deep-seated Whitlow (q. v.), when inflammation extends to one of the sheaths, and gives rise to the formation of adhesions, the motion of the enclosed tendon is destroyed, and a permanently stiff finger is the result.

The *synovial fluid*, or *synovia*, derives its name from its resemblance to the white of an egg (Gr. *syn*, with, and *oön*, an egg). It consists of water, holding in solution mucin, albumen, extractive matters, fat, and inorganic salts. The analyses of Frerichs shew that the composition and quality of the synovia vary essentially according as an animal is at rest or leads a wandering life.

SY'NTAX (Gr. *taxis*, arrangement, *syn*, together) is the part of grammar that teaches the putting together of words for the expressing of thoughts; in other words, it treats of the construction of sentences. The first step is the analysis of sentences—the study of their anatomy and physiology, as it were (see SENTENCE). This important part of the subject is too often altogether overlooked. A clear perception of the mutual relations of the several members of a sentence makes the usual rules of syntax appear self-evident truths, and in most cases superfluous. Most of these rules fall under the heads of (1) Concord and Government, and (2) Order of Words, or Collocation. For details, we must refer to special works on the subject.

SY'NTHESIS (Gr. *synthĕsis*, making a whole out of parts) is a term employed in chemistry to designate the building up of a more or less complicated product from its elementary constituents. As the synthesis of inorganic compounds is usually very simple, we shall confine our remarks to organic compounds. To take a very common substance as an illustration, there is no difficulty in resolving sugar into its ultimate elements, or, in other words, in ascertaining its composition by analysis. If we heat a little sugar to redness in a glass tube, it leaves a black deposit, which is carbon, while a liquid, which is water, distils over; and on electrolysing this liquid, we resolve it into hydrogen and oxygen; so that we can thus shew that sugar is composed of the ultimate elements, carbon, hydrogen, and oxygen. An analysis of this kind shews that sugar may be represented by the formula $C_{12}H_{22}O_{11}$, and that one atom, or any given weight of it, contains 144 atoms or parts by weight of carbon, 22 of hydrogen, and 176 of oxygen. This pulling to pieces of the sugar is an easy matter, and has been known to chemists for more than half a century; but the putting together of the pieces, or, in other words, the synthesis of sugar, is a very much more difficult task. We may bring together carbon, hydrogen, and oxygen in the due proportions, and, to use the words of Professor Wanklyn (in a lecture delivered at the Royal Institution, February 12, 1864), 'we may shake them all together, or heat them, or cool them, and yet we shall never get them to combine so as to form sugar. Alcohol consists of 24 parts of carbon, 6 parts of hydrogen, and 16 parts of oxygen; but no alcohol ever results from making such a mixture. Neither sugar nor alcohol can exist at the temperature to which it is requisite to raise our mixture of carbon, hydrogen, and oxygen, in order to get chemical action to set in. At ordinary temperatures, the organic elements will not enter into combination, whilst at high temperatures they combine, it is true, but yield comparatively very few compounds.' There was a general belief that organic products, such as sugar, alcohol, urea, oxalic acid, taurine, leucine, &c., required for their production a mysterious so-called *vital force*, totally distinct from the ordinary forces acting on matter. The first blow to this now obsolete doctrine was struck by Wöhler in 1828, when he discovered that the organic base *urea* might be artificially obtained. See ORGANIC COMPOUNDS. Three years afterwards, Pelouze obtained *formic acid* from inorganic materials. In 1845, Kolbe, by a somewhat complicated process, effected the synthesis of *acetic acid*, and consequently, indirectly, of its derivatives, amongst which may be enumerated *acetone*, the product of the destructive distillation of acetates; *marsh gas*, obtained by distilling an acetate with a caustic alkali, and *ethylene;* and the electrolysis of acetic acid, which Kolbe accomplished a few years afterwards, yielded methyl and oxide of methyl, which latter could be transformed into any other methylic compound. During the last sixteen years, new and simpler methods have been suggested by various chemists, amongst whom Berthelot must be

especially mentioned, and enormous additions have been made to the list of so-called organic compounds which have been synthetically constructed. We shall give a description of the mode of producing alcohol synthetically, and shall then shew that from it, as a starting-point, an immense number of other organic compounds can be synthetically produced. To obtain this product synthetically, several distinct steps are necessary. The first is the formation of a transparent colourless gas, acetylene, C_2H_2, from carbon and hydrogen in the electric arc; by passing this gas through subchloride of copper, acetylide of copper is produced, which, in contact with nascent hydrogen, gives ethylene (olefiant-gas), C_2H_4; agitated with sulphuric acid, ethylene produces ethylsulphuric acid (sulphovinic), $(C_2H_5)HSO_4$ (discovered by Faraday and Hennell in 1820). On distilling this acid diluted with water, dilute alcohol comes over, which, on redistillation, in contact with quick-lime, yields pure *vinic or ordinary alcohol*, C_2H_6O. Having thus obtained ordinary alcohol from inorganic materials only, we may employ it to form by synthesis an immense number of other organic compounds. By means of what is known as 'the process of Mendius,' we can, as it were, step from one alcohol to the next above it. Thus, from ethylic alcohol (C_2H_6O) we obtain *propylic* (or *tritylic*) *alcohol* (C_3H_8O); from this we obtain *butylic* (or *tetrylic*) *alcohol* ($C_4H_{10}O$); from this, *amylic alcohol* ($C_5H_{12}O$), and so on. From the propylic alcohol thus obtained, we get by oxidation *propionic acid*, from which *lactic acid*, the acid of sour-milk, may be obtained; similarly, butylic alcohol yields butyric acid, every alcohol, in short, yielding a corresponding fatty acid by oxidation. *Glycerine*, the base of the fats, may also be obtained by a somewhat circuitous process. By combining glycerine with propionic acid, and with the other fatty acids which may be synthetically formed, we obtain several oils and fats similar to those which occur as natural products. The case of *taurine*, $C_2H_7NSO_3$, is even more striking; it is a product of various glandular metamorphoses, but its chief source is the bile, where it exists in conjugation with cholic acid as tauro-cholic acid. This highly complex substance can readily be formed in the laboratory from sulphuric acid, alcohol, and ammonia, each of which is capable of being built up from its constituent elements.

Sugar has been obtained by Berthelot from glycerine, a substance which is obtainable by purely inorganic means; but as he effected the conversion of the glycerine into sugar by the action of putrefying animal tissue, we can hardly regard the sugar thus formed as being of purely inorganic origin, although the animal tissue only acted catalytically, or as a ferment, and did not contribute any actual material to its formation. There is, however, no doubt that an unexceptional means of producing this important alimentary substance will soon be devised, since bodies strictly allied to sugar have been already obtained.* Another artificial compound of great interest in an industrial point of view, is *toluene*, C_7H_8, which has recently been obtained from phenyl, and which can itself be produced synthetically from alcohol. 'Starting,' says Dr Odling, 'from these two bodies, we may procure all the so-called coal-tar colours, with the brilliancy and variety of which most of us are now familiar. The red base or rosaniline, $C_{20}H_{19}N_3$, the violet base or triethylrosaniline, $C_{26}H_{31}N_3$, and the blue base or triphenylrosaniline, $C_{38}H_{31}N_3$, being producible in this way from their constituent elements, furnish admirable illustrations of the constructive powers of modern organic chemistry.'

We cannot conclude without adverting briefly to the possibility of economically replacing natural processes by artificial ones in the formation of organic compounds. On this subject, one of our most distinguished organic chemists, Dr Frankland, observes, that 'at present, the possibility of doing this only attains to probability in the case of rare and exceptional products of animal and vegetable life. By no processes at present known, could we produce sugar, glycerine, or alcohol from their elements at one hundred times their present cost, as obtained through the agency of vitality. But although our present prospects of rivalling vital processes in the economic production of staple organic compounds, such as those constituting the food of man, are exceedingly slight, yet it would be rash to pronounce their ultimate realisation impossible. It must be remembered that this branch of chemistry is as yet in its merest infancy; that it has hitherto attracted the attention of but few minds; and further, that many analogous substitutes of artificial for natural processes have been achieved.'

For further details on this subject, the reader is referred to Berthelot's *Chimie Organique fondée sur la Synthèse* (2 vols. Paris, 1860); to the same author's lectures on the *Leçons de Chimie professées en* 1860 *et* 1862; to various lectures by Wanklyn, Frankland, and others, delivered during the last two years at the Royal Institution; and to Odling's lectures *On Animal Chemistry*, delivered at the College of Physicians in 1865.

SYNTONIN, or **MUSCLE FIBRIN** (Gr. *synteinein*, to render tense), contains in 100 parts: carbon, 54·06; hydrogen, 7·28; nitrogen, 16·0?; oxygen, 21·50; and sulphur, 1·11. It is the principal constituent and the essential basis of all the contractile tissues. It may be obtained from muscular fibrin in the form of a coherent, elastic, snow-white mass; but whether it exists in the living body in a solid form or in solution, is undecided. Many recent physiological writers hold the latter view, and maintain that the phenomenon of cadaveric rigidity (*rigor mortis*) is due to its spontaneously coagulating after death.

SYPHILIS is, according to Dr Farr's system of nosological classification, to be regarded as belonging to the enthetic order of zymotic diseases (see NOSOLOGY and ZYMOTIC DISEASES). These diseases have the common property of being developed in the system after the introduction by inoculation or implantation of specific poisons. The poisons which produce diseases of this order may be introduced through any abraded cutaneous surface, or through mucous membranes, especially if any solution of continuity occurs. A morbid poison thus introduced into the system produces a specific effect both on the tissue at the place of insertion and on the blood, as soon as the poison begins to become absorbed; or, in other words, it produces both a constitutional and a local change. The absorbed virus seems to undergo the following changes in the living and infected body—viz. (1) Increase, (2) Transformation, and (3) Separation or Excretion. Taking our illustrations from the disease to which this article is specially devoted, the *increase* is shewn by the fact, that the pus from a single syphilitic sore may by inoculation be made to spread the disease a thousand-fold. The *transformation* is indicated by the successive phenomena which

* Carius, a trustworthy chemist, has announced that he has succeeded in forming *Phenose*, a kind of sugar, possessing all its chemical characteristics, from benzol. —*Ann. d. Chem. u. Pharm.*, December 1865.

supervene during the course of the disease. For example, syphilis is followed, as we shall presently shew, by a series of secondary and tertiary phenomena, which follow a tolerably uniform course in different patients. The *separation* or *excretion* of the poison may be accomplished in several ways. While in some of the more intense poisons—such as those of certain serpents—the whole mass of the blood seems rapidly affected, in others, as syphilis, 'a double process of the zymotic-like action seems to take place before the full effects which the poison is capable of producing are completed. The multiplication of the venereal poison, and its effects upon the system, seem to become developed during the existence of the hardening process which surrounds the infecting venereal sore. This is the first zymotic-like process, and is attended with a local papule, and perhaps an ulcer. From this local sore the system becomes contaminated, and in the blood a second process (of zymosis?) appears to be completed, by which the original poison becomes intensified, its pernicious influence more complete, and its specific, secondary, and tertiary effects are more fully developed.'—Aitken's *Science and Practice of Medicine*, 3d ed., vol. i. p. 666.

From this brief sketch of the nature of enthetic diseases, we turn to the consideration of the special disorder known as *syphilis*—a word whose origin is unknown. The terrible ravages of this disease amongst our soldiers and sailors, to say nothing of the fearful misery which it occasions in private life, afford more than sufficient apology for our introducing into these pages some of the most important details regarding this repulsive form of disease.* It is almost unnecessary to observe that syphilis is a contagious disease usually propagated by impure sexual intercourse. The following is a brief history of the course of the disease, if its progress is not checked by proper remedial agents. At an uncertain period, varying from three to ten days, after exposure to the infection, one or more venereal ulcers (commonly known as *chancres*) appear upon the generative organs. These ulcers present many varieties, which have been variously classified. The following arrangement, by Mr Henry Lee, Surgeon to the Lock Hospital, is an eminently practical one—viz. (1) The Hunterian or indurated or infecting chancre; (2) The non-indurated or suppurative chancre; (3) The ulcerative chancre; and (4) The sloughing chancre. These local affections are so different in their characters, and in their action on the constitution, that each must have a brief separate notice. (1) The *indurated*, or, as it is frequently termed, the *Hunterian chancre*, from its having been first accurately described by John Hunter, is the only one of these local affections that can be associated with constitutional syphilis. Its natural course is thus described by Mr Lee. 'At an uncertain period, but generally from three to four days after exposure to infection, attention may be drawn to the part by a slight itching. On examination, a red spot, surrounded by a little induration, will perhaps present itself, or a vesicle about the size of a millet-seed will not unfrequently form upon the infected part. The cuticle covering this vesicle is so thin that it usually gives way at a very early period; and this commonly happens before the disease has been carefully examined. The base of the vesicle then becomes indurated, and the induration (whether preceded or accompanied by a pimple or a vesicle, or independent of either of these) assumes a circular form, extending equally in every direction, and terminating quite abruptly in apparently healthy parts. A sore generally follows; this is excavated, without granulations, sometimes glazed, at other times having some adhesive matter on its surface. The colour of the chancre will depend often upon the amount and character of the substance which adheres to it, and will frequently present a fawn hue, or different shades of brown and red. When this adventitious matter is removed, the sore will usually again assume its original smooth and red glazed appearance.'—'Syphilis' in Holmes's *System of Surgery*, vol. i. p. 400. This variety of sore frequently gives rise to a chronic enlargement of one of the glands of the groin (forming what is termed a *bubo*), which does not involve the skin or the cellular membrane. It is followed by certain constitutional symptoms known as *secondary symptoms*, and requires, both in its primary and secondary forms, mercurial treatment. (2) The *suppurating chancre* usually begins as an abrasion, which, when fully developed, often presents the same appearance as if a piece of skin had been removed by a circular punch. The sore is covered with ill-formed granulations, and extending equally in all directions, maintains its circular form. After continuing three or four weeks, it generally heals, without leaving the hardness which is so characteristic of the Hunterian, infecting or indurated sore. Another important diagnostic difference is furnished by the microscopico-chemical examination of the fluid secreted by the sore. In this suppurating sore, the secretion consists of pus, which, on the addition of acetic acid, exhibits the characteristic compound nuclei; while in the infecting sore the secretion resembles turbid serum, presenting none of the characters of the pus. It does not give rise to bubo, nor is it followed by secondary symptoms. (3) The *ulcerative chancre* is a ragged worm-eaten ulceration; secreting an ill-formed pus, and presenting an irritable surface. Soon after the appearance of this sore, one of the glands of the groin will become enlarged and painful. This may be preceded by a shivering fit, more or less marked. The enlarged gland or bubo becomes very tender to pressure, and as the swelling increases, the skin becomes red, especially at the centre, and the general symptoms of suppuration present themselves. Great relief is afforded by the discharge of the pus. It is never followed by secondary symptoms, and, like the preceding form, requires only local treatment. (4) The *sloughing chancre* is fortunately rare in this country, but in many foreign ports, in warm and

* Dr Aitken observes that 'no statistical nosology gives any idea of the number of men lost to the public service from syphilis. The loss of strength from venereal diseases alone (gonorrhœa being included with syphilis in this term, and forming about 40 per cent. of the cases) is equal to the loss of more than eight days annually of every soldier in the service.' Dr Balfour in his *Medical, Sanitary, and Statistical Report of the Army Medical Department* for 1860, relates that 'more than one-third of all the admissions into hospital have been on account of venereal diseases (369 per 1000), and the average number constantly in hospital is equal to 23·69 per 1000 of strength (2315 men), each remaining in hospital on an average 23½ days. Thus the inefficiency is constantly equal to about 2½ regiments.' In 1861, these diseases caused a loss equal to 8·69 days for every soldier serving at home, there being a daily inefficiency of 2077 men; and the numbers are nearly the same for the succeeding years. The daily loss of service in the navy, in 1862, was about that of 586 men per day. How far these data apply to our civil population, it is hard to say; but it is much to be feared they apply pretty closely. 'It is a question,' says Dr Parkes, 'whether a large majority of the young men of the upper and middle class do not suffer in youth from some form of venereal disease. In the lower classes, it is perhaps equally common.'—*Practical Hygiene*, p. 453. For a comparison between the amount of venereal disease in our own and other armies, the reader may consult the same work, pp. 502, 503.

hot countries, this form of syphilis commits great ravages amongst our sailors, who have given to it certain characteristic names, such as the *black-pox*, the *black lion*, &c. It does not affect the inguinal glands, and is not followed by constitutional symptoms, and requires only local treatment.

Before noticing the constitutional or secondary symptoms which follow the Hunterian or infecting sore, we shall very briefly describe the treatment required for the last three forms, in which no constitutional symptoms occur. A suppurating sore should at once be thoroughly cauterised, so as to destroy all the tissues which have imbibed the poison. To secure this result, strong caustics are desirable; and as they sometimes extend further than is desired, an antidote should be at hand, which not only checks the further extension of the caustic, but deadens the pain. The agents most used in these cases are caustics and the mineral acids, and the *potassa cum calce*, a combination of potash and lime, which is prepared in the form of small rods for this purpose. The last of these is on the whole the best, as the extent to which it acts may be accurately regulated. When the action is sufficient, the application of a dilute acid will relieve the pain. Nitrate of silver, which is often employed, is not sufficiently energetic in its action to eradicate the disease. In the ulcerative sore, which is often irritable and painful, opium is useful both locally and internally. In other respects, the same treatment must be adopted as in the preceding variety. As the various means that have been suggested for preventing the suppuration of the bubo, which always accompanies this sore, are of no avail, it is useless to mention them. If, after the bubo has burst, the remains of an indolent, enlarged gland, incapable of forming healthy granulations, are left, caustic must be applied, so as to cause them to slough away. In sloughing sores, the great object is to check the destructive process; for which purpose, fomentations and poultices are applied locally, and large and repeated doses of opium are given internally. The nitric acid lotion, or a solution of potassio-tartrate of iron (10 grains to an ounce of water), is often an efficient local application in these cases.

We now return to the consideration of the Hunterian or indurated chancre, the only variety of venereal sore that gives rise to secondary or constitutional symptoms. If the patient seeks medical assistance as soon as he perceives the sore, it is possible that the application of a caustic will destroy the poison, and prevent any constitutional symptoms. If, however, four days or more elapse before treatment commences, the best local application is some form of mercury, as mercurial ointment spread on lint, or the application of black wash (see LOTIONS) steeped in the same material. When the poison has once entered the circulation, and become diffused throughout the body, it is desirable to neutralise it, if possible, before the appearance of any secondary symptoms. A very large number of drugs have at different times possessed an anti-syphilitic reputation, and a few are doubtless useful; as, for example, iodide of potassium. 'There is one medicine alone,' says Mr Henry Lee, one of the highest British authorities on the subject, 'which, through good report and evil report, in spite of the strongest prejudices of some against its use, and the no less adverse influence of others, who have employed it to an unjustifiable extent, has maintained its general reputation.'—*Op. cit.*, p. 418. In these remarks on the value of mercury (if judiciously given) we fully concur; but the mercurialists and non-mercurialists are almost equally divided. It may be given internally in pills or in solution; or it may be introduced into the system through the skin, in the form of ointment; or lastly, it may be employed in the form of vapour and thus applied to the skin. Of these three methods, none is equal to mercurial fumigation by calomel vapour, either in the readiness with which it removes the symptoms, or the slight disturbance it excites in the constitution, or in its certainty in preventing relapse. This process is a very simple one. A piece of brick must be heated to a dull red heat, and placed in a pan having a little water at the bottom. A quantity of calomel, varying from 10 to 20 grains, is placed on the top of the brick; and the patient then sits over the pan in a cane-bottomed chair, enveloped from his neck downwards in a large blanket.* The operation is best performed at bedtime; it is complete in a quarter of an hour; and when the patient is sufficiently cool to put on his night-shirt, he should go to bed without disturbing the calomel on the surface of the skin. It is almost impossible to produce salivation by this means of administering mercury; and all that is requisite is to produce a slight tenderness of the gums. The system must be kept under this gentle influence of the mercury till the induration in the primary sore has disappeared. At a period usually varying from one to two months after the first appearance of the induration (which is regarded by some writers as the first of the secondary symptoms), slight febrile symptoms, usually followed by an exanthematous eruption of the skin, often accompanied by sore throat, will occur. This eruption is a variety of *roseola;* it is of a rose-red colour, which disappears on pressure, and is not raised above the surface. It generally disappears in a few days, but if it persist, it will gradually change to a copper colour, which is characteristic of all syphilitic eruptions which remain for a considerable time without suppurating or ulcerating. The syphilitic eruptions which usually follow this primary rash may assume the varied forms of lichen, syphilitic tubercle, lepra, and psoriasis; and the best mode of treating them is by applying local mercurial fumigation, and at the same time giving iodide of potassium (in five-grain doses thrice a day) internally. Occasionally, in persons with impaired constitutions, syphilitic eruptions assume a pustular character. For a description of these eruptions, we must refer to Cazenave's *Manual of Diseases of the Skin*, translated by Burgess. Similarly, there are cases in which, from some constitutional peculiarity, or, as Mr Lee suggests, from some want of power in carrying out the natural processes of the disease, the syphilitic eruption may be accompanied by an effusion of serum only; or, in other words, may be of the vesicular type. Thus, we hear of syphilitic herpes, syphilitic eczema, &c. These forms must be treated as the others.

Amongst the secondary syphilitic diseases of the mucous membrane, may be especially noticed (1) mucous tubercles, (2) deep ulcer of the tonsils, and (3) syphilitic laryngitis. *Mucous tubercles* appear as small tense eminences inside the cheeks, on the arches of the palate, on the lips, on the generative organs, and on the rectum. A solution of corrosive sublimate applied locally (one or two grains to the ounce of water), or calomel, proves an effective local application. *Deep ulcer of the tonsils* is best treated by corrosive sublimate given internally, in doses of $\frac{1}{12}$th of a grain three times a day, in compound tincture of bark and water; and also used as gargle (in the proportion of 2 grains to a mixture of 7 ounces of

* A simple apparatus for mercurial fumigation, consisting of a kind of tin case containing a spirit-lamp, may be procured from Messrs Savigny and Co., St James' Street, by those who object to rough bricks and coarse pans. A special fumigating cloak, in place of the blanket, is sold with the apparatus.

water and 1 of honey). *Syphilitic ulceration of the larynx*, commonly known as *Syphilitic laryngitis*, is characterised by pain or tenderness in the region of the thyroid cartilage (see LARYNX), huskiness of the voice, a hacking cough from attempts to expectorate, with occasional expulsion of purulent matter mixed with blood. If the disease is not checked, enervation, night-sweats, and dangerous exhaustion, ensue, and life is often terminated by suffocation.

In noticing the secondary symptoms, *syphilitic iritis* must not be overlooked; its symptoms and treatment are described in the article IRITIS.

Our limited space precludes more than a very brief allusion to the more important *tertiary syphilitic affections*. The most important of these are those which attack the bones and their coverings. They may be included under the heads of acute and chronic periostitis (the latter being very common), nodes and exostosis, inflammation of bone, caries and necrosis; next to these are tertiary affections of the skin and mucous membrane, which consist mainly of intractable ulcerations attacking the face (especially the nose and lips), nails, ears, and mucous membranes of the various openings of the body; and diseases of the glands. In many of these cases, a modified form of mercurial fumigation is most useful; but if mercury, even in this form, is thought inexpedient, in consequence of the general debility of the system, iodide of potassium, combined with any of the preparations of sarsaparilla, may be employed. Bark, iron, and the mineral acids are also of service in restoring the strength; and opium, by relieving the nocturnal pains which are so frequently present, will also prove most useful. The reader who wishes to pursue this subject further, may be referred to Aitken's *Science and Practice of Medicine*, in which he will find an account of the tertiary syphilitic affections of the nails, heart, brain, lungs, liver, and tongue.

The SYPHILIS OF CHILDREN is a subject which must not be omitted in an article on this disease. If the constitution of either the father or mother of an infant is saturated with the syphilitic poison, the child may be born with certain symptoms indicating that it is suffering from *congenital syphilis*. Moreover, the child of a mother having a primary sore, but no constitutional symptoms, may be inoculated with syphilis during the act of delivery; or the disease may be communicated in vaccination (if the matter be derived from an impure source); or by contact with syphilitic sores on the persons of wet-nurses or others. All these cases are included in the *infantile* variety of the disease. One of the most striking symptoms of true congenital syphilis is that which is popularly known as the *Snuffles*, in which a discharge collects in the nose, and sometimes blocks it up so completely that the infant is unable to suck for any length of time. The skin presents an eruption of spots, which are usually somewhat coppery, but sometimes of a rose-red tint; while on the soles of the feet and the palms of the hands, the cuticle scales off, and an appearance like that of psoriasis is presented; and flat mucous tubercles occur at the parts where the skin and mucous membrane merge into one another. White ulcers of a crescentic form often occur in the mouth; and with these symptoms there is nearly always observed 'the wizened and shrunken look, the anxious expression, and the dirty hue of the skin (a kind of dirty greenish yellow), which imparts to the infant a peculiarly repulsive aspect of old age.'—Holmes, 'On the Surgical Diseases of Childhood;' *op. cit.*, vol. iv. p. 830. Congenital syphilis frequently causes the death of the fœtus at about the fourth or fifth month; and if a woman is repeatedly delivered of dead children from the fourth to the seventh month, the practitioner may fairly conclude that a syphilitic taint is *probably* present. In other cases, the child is born alive with the 'snuffling' and eruption; but in the majority of cases, the infant when born is apparently healthy, and the disease does not shew itself till about six weeks after birth.

When congenital syphilis is diagnosed with certainty, the medical attendant has a very important duty to perform, from which he must not shrink from any feelings of delicacy. He must discover which of the parents is affected, and must prohibit further cohabitation until the secondary symptoms have been completely removed by the treatment which has already been described. 'Neglect of this precaution,' says Mr Holmes, in his excellent memoir on Congenital Syphilis (contained in the 4th vol. of his *System of Surgery*), 'may not only entail on the couple the misery of a family of deformed, puny, and ailing children, but to the woman at least is fraught with grave personal danger. Whatever may be the case amongst the poor, there is no doubt that, in the better classes, congenital syphilis is usually derived from the father, the mother being unaffected except through the fœtus.' There is scarcely a doubt that a woman carrying a syphilitic fœtus may become thus infected with secondary syphilis by the exchange of fœtal and maternal blood in the placenta; and this explains how it is that women who have never had the primary infecting sore, occasionally shew all the symptoms of secondary syphilis after living for some years with husbands similarly affected.

Allusion has already been made to the fact, that *infantile* (not *congenital*) syphilis may be communicated by vaccination. There is undoubted evidence that in the year 1861, in a thinly populated district of Piedmont, in which syphilis is virtually unknown, 46 children of various ages were simultaneously attacked with syphilis proceeding from chancres in the arm, and followed by buboes (enlarged glands) in the armpits; and that all these children had been vaccinated directly or indirectly from a single child, who was subsequently proved to have contracted syphilis from a wet-nurse; and further, that these children transmitted the same disease to a number of women, their wet-nurses, mothers, &c., and even to children who nursed and played with them; that the women so infected communicated the disease to their husbands; and finally, that the disease yielded in all cases to the ordinary treatment adopted in syphilis. This, as Mr Holmes observes, is by far the most convincing instance of the propagation of syphilis by vaccination; but several others are recorded by Mr Lee (*Lectures on Syphilitic Inoculation*, 1863) and other writers.

Cases in which the nipple of the wet-nurse has been infected by a syphilitic infant are by no means rare, and have in various instances given rise to litigation.

Congenital syphilis and infantile syphilis generally must be treated with mercury—either in the form of inunction, by keeping a flannel band, smeared twice a day with mercurial ointment, in constant contact with the thigh or arm for about six weeks; or internally, by the careful use of Gray Powder (*Hydrarg. c. cretâ*), in doses of a grain and a half or two grains, twice a day; combined with a little compound chalk-powder, if any irritation of the bowels occurs. The snuffles will be relieved by syringing the nostrils with lukewarm water, and then introducing a couple of drops of almond or olive oil.

In a foot-note to an early paragraph of this article, we gave abundant evidence of the appalling

prevalence of this disease. In his valuable treatise on *Practical Hygiene*, Dr Parkes discusses the question of the prevention of this disease amongst soldiers; as, however, his remarks for the most part are applicable to other classes, we shall briefly notice them. The means of prevention which he discusses are—1. *Continence*, which is promoted by (*a*) The cultivation of a religious feeling and of pure thought and conversation; (*b*) The removal from temptation and occasions to sin; (*c*) Constant and agreeable employment, bodily and mentally; and (*d*) Temperance. 2. *Early marriages*. At present, only six per cent. of the soldiers of the British army are allowed to marry. 3. *Precautions after the risk of contagion*. In some French towns, the use of lotions and washing is rigorously enforced, with the effect of lessening disease considerably. 4. *Cure of the disease in those affected by it*. Health-inspections, in special reference to venereal diseases, are made weekly in the British army by the surgeon or assistant-surgeon; and although similar inspections of all recognised prostitutes have long been made by legal authority in many parts of the continent, no attempt at legal interference with the disease in women was made in England till 1864, when the 'Contagious Diseases Bill' was passed, by which, in the neighbourhood of certain places (Portsmouth, Plymouth, Woolwich, Chatham, Sheerness, and Aldershot), prostitutes who are found diseased may be taken to a hospital, and there detained till cured. A committee appointed by the British government to report upon the best means of checking the disease in the army and navy, made a report in Feb. 1866, and issued their recommendations; the most important of which are—(1) The periodic inspection of all known prostitutes in the garrison towns placed under the provisions of the act of 1864; (2) the appointment of a surgeon vested with the necessary powers; (3) punishment for infringement of the act; (4) the extension of its operation to all garrison and seaport towns used by troops or ships; (5) the prohibition of the residence of public women in beer-shops; (6) that the lock hospitals be placed under government control; and lastly, that the police supervision of the women in the streets of such towns be more stringent. The evidence taken by this committee unquestionably proved that the working of the act of 1864 was decidedly useful, although its application was so limited. For an account of the various plans which are adopted on the continent for the prevention of this disease—such as the registration of brothels and of prostitutes, and the enforcement of periodic examinations at short intervals—the reader is referred to the various works of Parent-Duchatelet, Acton, Sanger, and others on Prostitution; and to two articles on the same subject by Dr Holland (of Cork) in the *British and Foreign Medico-chirurgical Review* for 1852.

Without entering into any prolonged details regarding the history of this disease, we may briefly mention that, towards the close of the 15th c., a great epidemic of syphilis pervaded Europe, and that it was supposed to have been imported from the New World; and that, in the 16th c., syphilis was recognised as the result of a specific virus. During last century, the history of this disease is divisible into three distinct periods, in each of which very different views have been prevalent. These may be described as—1. *The Period and Doctrine of Hunter*, who believed that the various forms of syphilis and gonorrhœa depend upon one and the same poison—a view taught by Carmichael in Dublin, Cazenave in Paris, and others. 2. *The Period and Doctrine of Ricord*, who proved that gonorrhœa was quite distinct from syphilis, and that inoculation with gonorrhœal matter will not cause a chancre; and that there are *two* classes of chancres, the *soft* and *hard*, originating from the same source. 3. *The Present Period*, commencing in 1856, in which it is held that, exclusive of gonorrhœa, there are *two* forms of the syphilitic poison. It has been judiciously advised by Mr Longmore, the Professor of Military Surgery in the Army Medical School, that in accordance with our present knowledge of this disease, the term *syphilis* or *syphilitic* should be restricted to such cases as are believed to be of a specific infecting kind, while the term *local venereal sore*, or *venereal ulceration*, should be applied to those cases which require merely local treatment, and are not followed by constitutional symptoms.

SYPHILISA'TION is the term used to designate an operation which has the double object of eradicating syphilis already existing in the system, and of securing permanent immunity from any future attacks, by means of repeated inoculations of syphilitic poison. As long ago as the year 1844, a French physician, Auzias Turenne, undertook a number of experiments, with the view of testing whether John Hunter's view, that syphilis could not be communicated to the lower animals, was correct. After some failures, he succeeded in producing venereal sores (chancres) in monkeys, by inoculating them with the human virus; and he found that rabbits cats, and horses might be similarly infected from the chancres of the monkey. He likewise found that the chancres produced by inoculation became less and less in each animal, until a period at length arrived at which the poison seemed to have lost all its power, and no further sores could be produced; and he was thus led to believe, that by prolonged inoculation, the system became protected. The subject was next taken up by Sperino of Turin, who inoculated patients suffering from syphilis by virus from a chancre, and repeated the inoculation once or twice a week, till the poison—as in the case of Turenne's animals—ceased to produce any effect; and when this point was reached, all the other sores had healed. In 1851, Professor Boeck of Christiania, when travelling through Italy, had his attention drawn to the doctrine of syphilisation; and from that time to the present, he has devoted himself unremittingly to it, and is now the great authority on the subject. He believes that syphilisation is the proper mode of treating syphilis in all its stages, and that—to use his own words—'in no disease have we a more certain method of cure. During the summer of 1865 Dr Boeck visited London, and took active steps to make his views on the subject accurately known in England, and the surgeons of the Lock Hospital admitted a series of cases to his mode of treatment; and Mr James Lane, one of the surgeons to that institution, in a discussion (February 1866) on this subject at the Harveian Society, observed, that 'if syphilisation would do what its advocates professed it would, we should have a remedy which, although undoubtedly severe in its operation, would do its work without any injurious effect on the system, and we should thus escape, in a very great measure, if not entirely, from all the more serious effects of the disease. Hitherto, as far as he had seen, it had effected everything which had been promised for it. The progress of the cases in the Lock Hospital had in almost every detail corresponded to the predictions of Professor Boeck respecting them. In several of those who had been longest under treatment, immunity from inoculation with primary syphilitic matter had been arrived at.' As almost all the speakers both at this meeting and at a late meeting of the London Medical Society

at which the same subject was discussed, spoke in favour of the system in so far as they had yet personally seen its effects, and advocated its further trial, there can be no doubt that if syphilisation has the claims upon our notice which Dr Boeck maintains, these claims must be soon universally recognised by the medical profession.

SY'RA (anc. *Syros*), the most important, though not the largest member of that group of islands in the Ægean Sea known as the Cyclades (see GREECE), lies 13 miles south of Andros. It is about 10 miles long by 5 broad, bare, hilly, and not very fertile. The products are wine, some wheat, barley, figs, honey, and vegetables; but the greater portion even of the common necessaries of life have to be imported from Greece and foreign countries. Its prosperity is of quite modern growth. During the War of Independence, S. remained neutral, and, in consequence, numerous fugitives flocked thither from other parts of Greece, especially from Chios and Psara, who, besides adding largely to the population, brought with them a spirit of political activity and commercial enterprise, the beneficial effects of which are now strikingly visible. Pop. 35,000. The capital, *Syra*, or *Hermopolis*, is situated on a bay on the east side of the island. It rises terrace-wise from the shore, is well built, and is the seat of government for the Cyclades, and the residence of foreign consuls. It has numerous educational institutions, 4 printing-presses, and 3 weekly newspapers. S. has become the great commercial entrepôt of the Ægean. Nearly one-half of all the imports of Greece reach it through this port. It builds more ships than any other town in the Levant, and owns one-third of all the Greek merchantmen. It has likewise regular steam-communication with all the principal trading-towns in the Levant. Pop. of the town of S. 20,000.

Ancient notices of S. are scanty. Homer praises it in the *Odyssey* as 'rich in pastures, in herds, in wine, in wheat;' but it has no history.

SY'RACUSE, anciently the most famous and powerful city of Sicily, situated on the south-eastern coast of the island, 80 miles south-south-west of Messina, was founded by a body of Corinthian settlers under Archias, one of the Bacchiadæ, 734 B.C. The original colonists seem at first to have occupied nothing more than the little isle of Ortygia, about one mile long, and half a mile broad, which lies near the shore. It rapidly rose to prosperity, and was enabled to establish sub-colonies of its own: Acræ (664 B.C.), Casmenæ (644 B.C.), and Camarina (599 B.C.). Nothing definite is known of the early political state of S.; but before 486 the political power had passed into the hands of a few leading families, or perhaps *clans*, who constituted an oligarchy, while the great body of the citizens formed a malcontent democracy. In that year a revolution took place. The oligarchic families—*Geomori* or *Gamori*, 'landowners;' probably the descendants of the original colonists, like the patrician *gentes* of Rome—were expelled, and the sovereign power was transferred to the citizens at large. Before a year passed, however, Gelon (q. v.), 'despot' of Gela, had restored the exiles, and at the same time made himself master of Syracuse. He was a great ruler, and under him the city increased in size and wealth. It is believed to have been in Gelon's time that the adjoining mainland was first built upon. The locality of the new settlers was the slopes and heights of Achradina, or the 'outer city,' a triangular table-land north of the island of Ortygia, and subsequently connected with it by a mole. It ultimately became the most extensive and populous quarter of S.—contained the Agora, a temple of *Zeus Olympios*, the Prytaneum, with a splendid statue of Sappho, the fine monuments to Timoleon and the elder Dionysius (q. v.), &c. It may be convenient to mention here the other two quarters of the city, especially as the date of their settlement is not known. These were Tyche—so called, according to Cicero, from an ancient temple of 'Fortune' erected there—occupying a plateau to the west of Achradina; and Neapolis (New City), stretching along the southern slopes of the plateau, and overlooking the marshes of the Anapus and the 'Great Harbour,' a spacious and well-sheltered bay, about five miles in circumference. Neapolis became one of the finest parts of Syracuse. Here were situated the theatre, amphitheatre, and numerous temples, of which hardly a relic remains, except of the first mentioned. Ortygia contained the castle or citadel which immediately fronted the mainland, and overlooked the docks or *navalia* in the 'Lesser Harbour.'

Reverting to the history of S., which we must touch upon only in the most cursory manner, a noticeable characteristic of the reign of Hiero (q. v.), the successor of Gelon, is his cultivation of the fine arts, and his liberal patronage of men of genius, as Æschylus, Pindar, &c. In 466 B.C., the democracy again got the upper hand—Thrasybulus, a 'tyrant' of the baser sort, being expelled; and for sixty years a free and popular government was enjoyed, under which S. flourished more than it had ever done. During this period occurred its great struggle with Athens (415—414 B.C.), in which it came off victorious, and its renown at once spread over the whole Greek world. But a new power appeared on the stage—the Carthaginian, whose conquests in Sicily, towards the close of the 5th c., threatened the supremacy of Syracuse. Meanwhile, Dionysius (q. v.) restored the 'tyranny' of Gelon, and during a reign of 38 years greatly increased the strength and importance of the city. It was he who constructed the docks in the Greater and Lesser Harbours, and surrounded the city with fortifications. His fierce and victorious war with Carthage (397 B.C.) raised the renown of S. still higher. The reigns of the younger Dionysius (q. v.) and of Dion were unsettled; but after the restoration of public liberty by Timoleon (344 B.C.), a brief season of tranquillity ensued, during which the prosperity of the city rapidly revived. Under Agathocles, however, the despotic form of government was again established (317 B.C.), and continued, with scarcely an interruption, down to the conquest of the city by the Romans (212 B.C.) during the Hannibalic war—the ruler of S., Hieronymus, a rash and vain young man, having abandoned the prudent policy of his grandfather, Hiero (q. v.), broken the alliance with Rome, and joined the Carthaginians.

Under the Romans, S. slowly but surely declined, though it always continued to be the capital and first city of Sicily. Captured, pillaged, and burned by the Saracens (878 A.D.), it sunk into complete decay, and is at present confined to its original limits, Ortygia, which, however, is no longer an island, but a peninsula. Pop. 19,400. The streets of the modern town are, with few exceptions, narrow and dirty. S. has a cathedral, a museum of classical antiquities discovered in S. and the neighbourhood, a public library, with some curious MSS., numerous churches, monasteries and nunneries, and carries on a trade chiefly with Malta in wine, oil, salt, and salt-fish. It has several remains of ancient and medieval edifices, which are much visited by travellers.

SYRACUSE, a city of Central New York, U. S. at the head of Onondaga Lake on the Erie Canal,

and at the junction of the New York Central and Oswego railways, 148 miles west-by-north of Albany. It contains a handsome court-house, state arsenal, state asylum for idiots, 37 churches, 3 daily, 10 weekly, and 2 semi-weekly newspapers, 13 banks, 18 public schools, and several libraries. Here are the largest salt works in America, which produced, in 1870, 8,748,113 bushels of salt; 5 iron furnaces, 14 machine-shops, manufactories of silver- and tin-ware, sheet-iron, coach- and wagon-factories, and breweries. Pop. in 1860, 28,199; 1870, 43,051; 1880, 51,791.

SY'RIA (Arab. *E'sham*, Turk. *Soristan*), a division of Asiatic Turkey, bounded on the N. by portions of Asia Minor, on the W. by the Levant, and on the S. by Arabia Petræa; on the E. and S.-E., its boundary is rendered indefinite, in great part, by the sands of the desert, but at length becomes fixed by the course of the Euphrates. It is divided into three governments: 1. That of Saïda (subdivided into 9 *livas*); 2. Scham (subdivided into 5 *livas*); and 3. Haleb (subdivided into 3 *livas*). Area estimated at about 146,000 sq. m.; pop. about 2,750,000. The whole region is traversed by a double mountain-chain—of which Lebanon (q. v.) forms the highest part—touching in its northern extremities the Alma Dagh (anc. *Mons Amanus*), and in its southern forming the Sinaitic range. The central part of this mountain-system, which in many places exhibits the characteristics of a plateau, presents on the west a steep front towards the Mediterranean, but on the east rolls gradually away into the level uplands of the Syrian wilderness. The most noticeable features of the long *furrow* between the double ridge, beginning at its southern end, the Gulf of Akaba, are, the waterless wady of Arabah, the narrow, deep-sunken region known as *El Ghur*, through which the river Jordan flows, and which embraces the Dead Sea and the Sea of Galilee, and the vale of Cœle-Syria (q. v.), and its great continuation northwards, watered by the Nahr-el-Asy (anc. *Orontes*). The western ridge is broken through in three places: in the north by the lower Orontes; in the middle near Tripolis—where the chain of Lebanon properly terminates—and further south, near Tyre, by the Leontes. South of Tyre, it recommences in the hill-country of Western Palestine (q. v.), which finally passes into the desert plateau of El Tyh, in the Sinaitic peninsula. The eastern ridge is less sharply defined; its most conspicuous elevations being Anti-Libanos, the mountains of Moab (east of the Dead Sea), and Mount Seir, overlooking the wady Arabah. The principal rivers are the Orontes (q. v.), the Leontes, the Jordan (q. v.), the Barada or Abana, the river of Damascus. The only lakes worth mentioning are the Dead Sea (q. v.) and the Sea of Galilee.

Although S. belongs to the countries comprised within the Asiatic rain-zone, yet in general the climate is excessively dry and hot, differing little from that of Arabia. Drought and scantiness of vegetation characterise almost equally the uplands and the valleys. Only where the mountains are lofty, the streams abundant, and the atmosphere somewhat maritime, as in the terraced slopes of Lebanon, do we find some approach to tropical luxuriance in flower, and fruit, and tree. Forests of evergreens, beautiful grassy pastures, and meadow-tracts are found there; and wheat, maize, rice, &c., are largely produced. The cultivation of the vine, the cotton-tree, the mulberry, and also the finer sorts of fruits, as the olive and fig, is considerable, while indigo and sugar-cane are raised in the valleys of the Jordan and the regions round about the Dead Sea. The fauna of S., like its climate and vegetation, is similar to that of Arabia. The camel is of almost as much importance as further south; and the Syrian deserts, particularly towards the north, are the home of gazelles, hyænas, jackals, bears, buffaloes, and other wild animals.

The greater part of the Syrian mountains is limestone; mountain limestone in Lebanon, chalk in Anti-Lebanon, and Jura limestone in Palestine. In the last of these, volcanic formations occur, especially in the region of the Jordan and the Dead Sea, where hot springs, beds of bitumen and sulphur, the shapes of the hills, and the frequent earthquakes, afford unmistakable evidence of volcanic activity. Salt is the only mineral of much consequence, and is exported in considerable quantities; coal, however, is worked near Beirût. Sheep, goats with hanging ears and silky hair, cattle, mules, and asses, form, as in ancient times, a great part of the wealth of the inhabitants.

Silk is the chief article of manufacture—at Aleppo, Beirût, Damascus, &c.—but cotton and woollen fabrics, gold and silver thread-stuffs, glass, earthenware, leather, soap, &c., are also manufactured in different parts of the country. The want of roads is a great hindrance to the development of industrial activity. Up to 1863, there was not a single carriage-road in the whole of Syria. In that year, one was opened between Beirût and Damascus. The other roads are mere mule and camel tracks. In 1862, S. exported grains, seeds, cotton, galls, wool, &c., to the value of £126,242; and imported cottons, woollens, copper, tin, iron, coals, indigo, pepper, coffee, &c., to the value of £603,513.

The *religious* sects of S. are numerous. Most of the people are Mohammedans; but Christians of the Greek Church number 350,000; Maronites (q. v.) and Roman Catholics, 260,000; Jews, 175,000; Druses (q. v.), 48,000; lesser sects about 17,000. The inhabitants are in some sense a mixed people, for the country has experienced many political vicissitudes; but by far the greatest number, whether Christians or Mohammedans, are of Shemitic origin, either Phœnician, Aramæan, or Arabic. Their Turkish rulers, however, and such Turkomans and Kurds as we find settled in the north of S., belong to the Turanian race. Arabic is everywhere spoken, and may be considered the national language, since the old Syriac or Aramaic tongue is wholly dead, except among the Nestorians of Kurdistan.

The *history* of S. stretches far back into remote antiquity. In the time of Abraham (2000 B. C.), Damascus was a city; in the oldest literature of Greece, Sidon figures as the capital of a rich, populous, and civilised state; and in the Hebrew Scriptures, Canaan or Palestine is crowded with towns at the period of its conquest by Joshua; but, like most other so-called nations in early times, S. did not form a single state; it was rather a congeries of independent states whose inhabitants belonged to the same race. Every important city had its king, whose normal occupation was fighting with his neighbours. Under David and Solomon, something like political unity was achieved; yet it does not appear that these great rulers dispossessed of their territories the princes whom they subdued, but only made them tributary, and after their death things reverted to their previous condition. Rezin, a slave, then made himself master of Damascus, and extended the Damascene monarchy over all Northern and Central S.; but the conquests of Tiglath-Pileser resulted in its becoming a province of the Assyrian Empire. Subsequently, the whole land, including Palestine, became part of the successive empires of Babylonia, Media, Persia, and Macedonia. Then followed the dynasty of the Seleucidæ (q. v.). After their fall, S. passed into the hands of the Romans,

who retained it, though not continuously — for on several occasions the Persian Sassanidæ (q. v.) managed to wrest it from them—until the Arab conquest (7 c. A. D.). During the Crusades (q. v.) of the middle ages, several Christian principalities were established here, but endured only for a short period. S. now became a possession of the sultans of Egypt, in whose time it was frightfully devastated by the Mongols. In the 16th c., it was conquered by the Turks, and has ever since formed part of the Turkish Empire.

SY'RIAC VERSIONS. Apart from the Peshito (q. v.), there were other Syriac versions of the Old Testament current among the Syrian Christians, although they did not acquire canonicity among them. These were chiefly translated from the LXX., and the best known among them is one drawn up from the text of the Hexapla (q. v.; compare also ORIGEN), which it follows most slavishly, without any regard for Syriac idiom or grammar. It contains the critical marks of Origen, and is moreover furnished with numerous variants, fragments from other Greek versions, and exegetical scholia. Bishop Paulus of Tela is supposed to have composed it at the instigation of Bishop Athanasius, 617 A.D. There are now only a few (imperfect) MSS. extant of it—one in Paris, one in the Ambrosian Library (a third, once in the possession of T. Masius, has disappeared), and further portions are found in the Nitrian collection in the British Museum. The greater part of the Biblical books has been edited from it, but in separate publications. A complete edition is still a desideratum. An attempt is now being made towards a more complete edition of the Hexapla itself by a reconstruction of lost portions of the Greek, through the medium of the parallel Syriac passages preserved in this translation. Two other MSS. in the Paris Library contain fragments of another Græco-Syriac version, by Jacob, Bishop of Edessa, who, in 703 and 704 A.D., composed it from the Peshito and the above translation, which is probably to be understood in the sense of his having made a new recension of Paulus of Tela's work, corrected after the Peshito.

SYRIAN RITE, CHURCH OF, that portion of the oriental church which had its seat in Syria, and which was anciently comprehended in the patriarchate of Antioch, and (after that of Jerusalem obtained a distinct jurisdiction) in the patriarchate of Jerusalem. The Syrian Church of the early centuries was exceedingly flourishing. Before the end of the 4th c., it numbered 119 distinct sees, with a Christian population of several millions. The first blow to the prosperity of the Syrian Church was the fatal division which arose from the controversies on the incarnation. See MONOPHYSITES, NESTORIANS, EUTYCHES, JACOBITES. The Eutychian heresy, in one or other of its forms, obtained wide extension in Syria; and the usual results of division ensued in the corruption and decay of true religion. The Moslem conquest accelerated the ruin thus begun; and from the 7th c. downwards, this once flourishing church declined into a weak and spiritless community, whose chief seat was in the mountains, and whose best security from oppression lay in the belief on the part of the conquerors of their utterly fallen and contemptible condition. Under the head MARONITES has been detailed the most remarkable incident in the later history of the Syrian Church. This branch of the eastern Christianity, although for the most part divided from the orthodox Greek Church by the profession of monophytism, took part with the Greeks in their separation from the west, under Michael Cerularius; and the reunion of the Maronites to Rome had the remarkable result of establishing side by side, within the narrow limits occupied by the Christians under the Moslem rule in Syria, two distinct communities, speaking the same language, using the same liturgy, and following the same rites; and yet subject to two different patriarchs, and mutually regarding each other as heretics and apostates from the ancient creed of their country.

The chief peculiarity of the Syrian rite, as contradistinguished from the Greek, consists in its liturgy, and the language of that liturgy, which is Syriac, and with which the people, and in many cases the priests, are entirely unacquainted. The liturgy is known as the Liturgy of St James. The Syrians agree with the Greeks in the use of leavened bread, in administering communion under both heads, in permitting the marriage of priests (provided they marry before ordination), and in administering the unction of confirmation at the same time with baptism, even to infants.

The Christian community of Syria may at present be divided into four classes: the Maronites, the Greeks (who are also called Melchites), the Monophysites, who are called Jacobites, and the primitive Syrian Christians (not Maronites), who are in communion with Rome. This last-named community forms the small remnant of the ancient Syrian Church, which remained orthodox during the controversy on the Incarnation, at the time of the general lapse into Monophytism. To these are to be added the Christians of the Latin rite. The Maronites number about 150,000; the Greeks are said to be about 50,000; the Jacobites of Syria and of Armenia Proper are said to reckon together about 40,000 families, of whom, however, but a small proportion (probably scarcely 10,000 in all) can be set down to the account of the Syrian Church. The non-Maronite Syrians who follow their national rite, but are in communion with Rome, are supposed to amount to about 4000. The resident Latins are chiefly members of the religious orders who from immemorial time possess convents in the Holy Land, and European Catholics, who have settled permanently, or for a time, at Jerusalem, Beirût, and Damascus. None of these can in any way be regarded as belonging to the Syrian Church. It may be well to add, that the belief, and in most particulars the disciplinary practice of these several classes coincide substantially with those respectively of the same communities in the other churches of the East. All (with the exception of the Maronites and the few United Syrians, reject the supremacy of the Roman see. The Syrians of the Greek communion reject the double precession of the Holy Ghost; and the Jacobites firmly maintain their old tenet of Eutychianism. Among them all are to be found monks and religious females. All enforce celibacy on their bishops, and refuse to priests the privilege of contracting a second marriage, or of marrying after ordination. The practice of fasting prevails among all alike. They receive and practise the invocation of saints and prayers for the dead, and the use of painted, although not of graven images. Many particulars regarding them are to be gleaned from the memoirs of recent missionaries of the several denominations, among which the letters published from time to time by the French Society for the Propagation of the Faith, although naturally tinged with some sectarian colouring, are particularly full and interesting.

SY'RINGE (Gr. *syrinx*, a pipe,), a hydraulic instrument, consisting of a cylinder of metal or glass, having a conical nozzle at one end, and the other fitted with an air-tight piston. The nozzle being inserted in a liquid, the retraction of the piston draws the liquid into the cylinder, on the principle of the Pump (q. v.), and by its forward

pressure the liquid is expelled from the nozzle in the form of a jet.

SYRRHA'PTES, a genus of birds of the Grouse family (*Tetraonidæ*), of which only one species is known (*S. Pallasii*), a native of the deserts of Tartary, abundant in the neighbourhood of Lake Baikal. From its peculiar characters, which led Pallas to call it *Tetrao paradoxus*, it has received the somewhat pedantic name of *Heteroclite Grouse*. (A word is called *heteroclite* by grammarians which departs from the ordinary forms of declension.) The legs and toes are short, and densely feathered; and the toes are joined together for the greater part of their length. The bird walks with difficulty, but flies very well, although in general only for short distances. The wings and tail are very long, terminating in remarkably long, slender, pointed plumes.

SY'RTIS MA'JOR AND SYRTIS MI'NOR, the ancient name of two gulfs of the Mediterranean Sea, on the north coast of Africa. The former (now called the *Gulf of Sidra*) lies between Cape Mesurata, in Tripoli, and the table-lands of Barca, and forms the most southern part of the Mediterranean. The latter (now called the *Gulf of Cabes*) lies to the north-west, between Tunis and Tripoli. The shores of both are inhospitable, and abound in quicksands, which, carried by the wind, are said by the ancients to have frequently overwhelmed ships, and the reports of modern travellers to some extent confirm these old traditions. Their waters are (or were) dangerous to sailors, on account of the shallows, sandbanks, and sunken rocks that abound in them.—The name Syrtis is derived from an Arabic word *Sert*, meaning a desert.

SY'RUP. *Syrup*, *sherbet*, and *shrub* are all derived from the Arabic *srb;* the first through the Latin, the second through the Persian, and the third through the Hindu. Syrup, in its simplest meaning, is a saturated solution of sugar boiled to prevent fermentation; but it also means the juice of fruits saturated with sugar and many flavoured liquids, treated in the same way. Generally speaking, the finest refined sugar is used; and every effort is made to get the syrup very clear and free from all feculent matter. Syrups of fruits are much used on the continent to mingle with water for drink, and are very wholesome. They are also used in Britain, but not much, except in medicine—there being many medicinal syrups.

SY'STYLE, an arrangement of classic columns in which the intercolumniation is equal to twice the diameter of the column.

SYZRA'N, a town of Central Russia, in the government of Simbirsk, on the right bank of the Volga, about 150 miles below the town of Simbirsk. It owes its foundation to its advantageous commercial position on the Volga, and in the middle of a district teeming with agricultural produce. From the wharfs of S., 150 vessels, laden with corn, are annually despatched to Rybinsk and St Petersburg. Pop. 20,525.

SZATHMA'R-NEME'THY, a town of Hungary, on the Samos, 60 miles north-east of Debreczin. Pop. 14,288.

SZE-CHUE'N (Four Streams), a vast province of Western China, and the largest of the eighteen. It has an area four times greater than that of England, but the population is scanty. The Kincha-kiang, or 'Golden Sanded River,' which rises in the southern slopes of the great Tibetan range, flows through S., and after receiving several tributaries, it becomes, before leaving the province, the famous Yang-tze-kiang. In its course, it passes at right angles, and by narrow gorges, through a succession of ranges of hills, which have a direction from north to south. The people of S. cannot always force a subsistence from their stubborn soil. Famines are not uncommon, when whole families are starved to death, and thousands subsist on a mixture of rice, roots, and common earth. Coal is abundant, but of inferior quality; seams of from three to five feet in thickness are laid bare in the gorges cut by the Yang-tze, and gold is found in small quantities, grains of the precious metal being brought by the Kincha river from the mountains of Tibet.

SZEGEDI'N, the second largest town in Hungary, is situated on the right bank of the Theiss, at the point where it is joined by the Maros, 118 miles south-east of Pesth by railway. S. is fortified, and has some fine buildings. It manufactures great quantities of soda, tobacco, coarse cloth, &c., has the largest wharfs on the Theiss, and carries on an extensive river-trade in wood and corn with Transylvania and the Banat. Most of the Turkish cotton imported into Austria passes through Szegedin. Its markets rank next to those of Pesth and Debreczin. Pop. 69,041.

SZEGSZA'RD, a town of Hungary, near the right bank of the Danube, 80 miles south-south-west of Pesth. Here excellent red wine is made. Pop. 10,500.

SZE'NTA. See ZENTA.

SZENTE'S, a market-town of Hungary, 30 miles north of Szegedin, near the left bank of the Theiss. The *commune* contains 26,000 inhabitants, who are chiefly engaged in the wine-culture.

SZOLNO'K, a town of Hungary, on the Theiss, 66 miles east-south-east of Pesth. It contains important salt-magazines, and is the centre of the traffic by steamers on the Theiss, and an important railway station. Pop. 13,936.

T

T THE twentieth letter of the English alphabet, is the sharp or mute of the lingual series *t*, *d*, *th* (*dh*). The name in Shemitic, where it stands last in the alphabet (*Tau*), signifies a mark (in the form of a cross). The Shemitic tongues had another *t*-sound, which became the Greek *θ* (*th*). This aspirated *t* is wanting in Latin and its derivatives; it is also foreign to High-German, although the Gothic and other Low-German tongues (English) possess it. The Gothic *th* has become in High-German *d*. In the *spelling* of High-German, *th* occurs not unfrequently; but it is never pronounced, and the introduction of it being considered by students of the language an aberration, there is a tendency to drop the *h*. There is evidence that in Latin, at an early period, *t* before *i* was sibilated so as to sound like *ts* or *z*. See letter C. Before *s*, *t* was frequently dropped; as *fons* for *fonts*, *sors* for *sorts*. Final *t* was in Latin pronounced but faintly, and inscriptions shew that in popular speech it was often dropped; e. g., *fece* for *fecit*, *vixse* for *vixit*. Thus the modern Romanic languages have inherited the loss of the pronominal ending *t* from their common mother. In French, *t* between two vowels has been elided; as *père*, *mère*, from *pater*, *mater*. In the corresponding words of the allied languages, *t* is often interchanged with other letters. T in Sanscrit, Greek, and Latin becomes *th* in Gothic and English, and *d* in High-German; thus Lat. *tres* (Sans. *trayas*), Goth. *thrais*, Eng. *three*, Ger. *drei;* Lat. *tectum* (Gr. *tegos*), Goth. *thak*, Eng. *thatch* or *thack*, Ger. *dach;* Lat. *frater*, Goth. *brothar*, Eng. *brother*, Ger. *bruder*. In German, the *t* of the English is often represented by *z*, as Eng. *two* = Ger. *zwei;* Eng. *toll* = Ger. *zoll;* while German *t* or *th* becomes Eng. *d*, as Ger. *tag*, *thau* = Eng. *day*, *dew*. A more remarkable interchange is seen in Lat. *lacrima* = Eng. *tear*. See PHILOLOGY.

TABA'NIDÆ, a numerous family of Dipterous insects, of the section *Proboscideæ*, which live by sucking the blood of horses, oxen, and other animals, and are popularly known by the name of GAD-FLY, which, however, is often given also to some of the *Œstridæ* (see BOT). The insects called CLEG (q. v.) are of this family. The proboscis is exserted, and is generally terminated by two lips; the palpi are also exserted; the antennæ are three-jointed, the third joint consisting of a number of rings. The T. fly with a buzzing noise. They are very annoying to cattle in the end of spring and early part of summer; and where they abound, the skins of cattle are often streaked with blood from their bites. The LARGE GAD-FLY (*T. bovinus*) is more common in some parts of the continent of Europe than anywhere in Britain, and is rarer in Scotland than in England. But the British T. are numerous. The species are widely distributed. Some of them

Gad-fly and larva (*Tabanus bovinus*).

inhabit the deserts of Arabia and Africa, and attack camels in prodigious numbers.

TA'BARD (Fr. *tabarre*, from *tabardum*, Low Lat.), a military garment in general use in the latter half of the 15th and beginning of the 16th c., which succeeded the *Jupon* and *Cyclas*. It fitted closely to the body, was open at the sides, had wide sleeves or flaps reaching to the elbow, and displayed the armorial ensigns of the wearer on the back and front, as well as on the sleeves. About the middle of the 16th c., the tabard ceased to be used except by the officers of arms, who have down to the present time continued to wear tabards embroidered with the arms of the sovereign.

TABASHEE'R, a substance sometimes found in the cavities or tubular parts of the stems of bamboos and other large grasses. It consists chiefly of silica, with a little lime and vegetable matter, or sometimes of silica and potash, in the proportions of about 70 parts of silica and 30 of potash. It appears to be formed by extravasation of the juices of the plant, in consequence of some diseased condition of the nodes or joints. It is in high repute among the Hindus as a tonic, and is prepared by imperfect calcination and trituration. The powder is often chewed with betel, in order to renovate the constitution. There are several varieties of tabasheer, one of which, of very rare occurrence, is extremely beautiful, of a delicate azure colour by reflected light, and of a faint yellowish hue by transmitted light, easily crushed between the fingers, and of 'an aërial and unsubstantial texture, which we look for in vain in any other solid.' Other varieties are yellowish, white, and much like some varieties of opal. Tabasheer is very porous, and absorbs water and oil very rapidly; effervescence taking place when it is plunged in water. By absorption of oil, the opaque varieties become transparent. When the greater part of the oil is expelled by heat, the

structure of the tabasheer becomes apparent; it is beautifully veined, the veins being sometimes parallel, and sometimes curved. The optical properties of tabasheer are remarkable. Of all known substances, it has the lowest refractive power.

TABBY, or TABBYING, another name for watering fabrics. See MOIRE. It is usually applied to stuffs or worsted cloths instead of silks.

TA'BERNACLE (Heb. *Ohel Moed* = tent of meeting, *scil.*, between God and man; LXX. *Skene*, Vulg. *Tabernaculum Fœderis*), or, more fully, 'Tabernacle of the Congregation,' was the tent first erected by Moses in the desert as a visible symbol of the Divine Presence in the midst of the people. It was the place where he went to receive his inspirations as their representative, when they 'came to seek Jehovah.' A cloudy pillar descended and stood at the door of the Tabernacle while 'the Lord spake to Moses.' The detailed description of the Tabernacle contained in Ex. xxv. seqq., xxxvi. seqq., renders more than a brief outline superfluous in this place. Suffice it to mention that it was divided into the 'Sanctuary' proper—which formed the front part, and the dimensions of which were 20 cubits in length, 10 in width, and 10 in height—and the 'Holy of Holies,' which was 10 cubits square, and 10 high. A kind of court-yard, formed by curtains suspended between columns, ran round the Tabernacle, 100 cubits long, and 50 wide. The entrance was towards the east—the rising of the sun—and closed by another costly curtain, into which, like unto the first covering, figures of 'cherubim' were woven. The surrounding court was much larger on this eastern than on the western side, for here it was that the people assembled for the purpose of worship. Here also stood the altar, made of acacia-wood, upon which a perpetual fire was kept burning, and the brazen laver. The *Sanctuary* contained the gilded table with the shewbread to the right, the golden candlestick with the seven branches to the left, and between both the 'golden altar,' or the 'altar of incense,' upon which the high-priest burned incense in the morning and evening. In the Holy of Holies, the holy ark, or Ark of the Covenant, alone was kept: a box of acacia-wood, plated with pure gold both in and outside, containing the two tables of the Ten Commandments. On the top of it were the two cherubim, their faces turned towards each other; and between them there was the symbolical presence of Jehovah (the Shechinah), to which Moses appealed for guidance.

Only once a year, on the Day of Atonement, the high-priest was allowed to enter the Holy of Holies, while the Sanctuary was the ordinary place of the priests, and the court that of the Levites. The tribe of Levi was also that to which the place nearest to the Tabernacle, around which the twelve tribes were grouped, was assigned, as it also was the duty of its members to convey the building from place to place during the migrations.

The Tabernacle, after the people had settled in Canaan, was erected at Shiloh, where it was still found at the time of Saul, although the Ark of the Covenant itself had been carried away by the Philistines, in the time of Eli, and when restored, placed at Kirjath-jearim. Nor was the Tabernacle of Shiloh the only sanctuary, as it was intended to be. We find other local sanctuaries with priests—at Bethel, Nob, Sichem, Mizpah, &c.—at which even Samuel worshipped, as in legally instituted places. When David is reported to have removed the Ark from Kirjath-jearim to Jerusalem, nothing is said about the Tabernacle of Shiloh; on the contrary, David erected a new one on purpose for the Ark. It seems probable that it was removed at some time or other from Shiloh to Nob, and thence to Gibeon, from whence Solomon seems to have fetched it away, with all its vessels, thus putting an end to the double worship that under David had divided the faithful between Gibeon, where Zadok officiated, and Jerusalem, with Asaph's worship. Nothing is further known of the Tabernacle, which, besides being a symbol of God's presence, had also served the purpose of a visible political and religious link between the tribes. As a safeguard against idolatry and unlimited sacrificial worship, however, it did not prove effective enough.

TABERNACLE (Lat. *tabernaculum, armarium*), in the Roman Catholic Church, is the name given to the receptacle in which the consecrated elements of the Eucharist are retained. The name is derived by analogy from the tabernacle of the Old Law, and in form the Roman Catholic tabernacle bears a general resemblance to the Jewish original. By the present discipline, the tabernacle is commonly a small structure of marble, metal, or wood, placed at the posterior part of the altar, and of costly material and workmanship. Even when the exterior structure is of marble or metal, there is commonly an inner receptacle of wood (properly cedar), lined with silk. The tabernacle is appropriated exclusively to the reservation of the Eucharist, and it is prohibited to keep within it any other object, however sacred, as the chrism, relics of saints, the altar-vessels, &c. A lamp is constantly kept burning before the tabernacle, which is ordered to be kept at all times carefully locked, the key being retained by the clergy, to whom it is forbidden to intrust it to any lay person, even the sacristan or other official of the church.

TABERNACLE, FEAST OF (Heb. *Succoth*, LXX. *Heorte skenon*, Vulg. *Feriæ Tabernaculorum*), a Hebrew feast of seven days' duration, beginning on the fifteenth day of the seventh month (Tishri), and instituted principally in memory of the nomad life of the people in the desert, and the booths or tents used on their march. Besides this signification, it also had an agricultural one, like the other two pilgrimage festivals, the Passah and the Feast of Weeks. It was emphatically the Feast of 'Ingathering'—i. e., the close of the labours of the field —the harvest of all the fruits, of the corn, the wine, and the oil. During this feast, the great bulk of the people were enjoined to dwell in booths, which we learn from Nehemiah viii. 15, were made of olive, pine, myrtle, palm, and other branches, and were erected on the roofs of houses, and in the courts and streets. The scriptural injunction, to take trees and 'boughs of goodly branches of palm-trees,' &c., was by tradition explained to mean a bunch made of palm, myrtle, and willow branches, and the esog-fruit, a species of citron, which the faithful carried in procession during these seven days in the Temple; while those who did not visit the Temple only said a benediction over it on the first day. The Sadducees and Karaites, however, demurred to this explanation, taking the passage merely to refer to the construction of the booths. Special sacrifices, and a greater number of burnt-offerings than on any other festival, were offered up on this; and on it also the law was to be read to the people every seventh year. It was emphatically called *the* festival, and was the most joyous of them all. There was especially, during the time of the Temple, the 'joy of the libation,' consisting of the priest's fetching, during the morning sacrifice of each day, water from the well of Siloah, and pouring it out, with the accompaniment of music and hymns. There was further a grand illumination in the evening in the court of women, which is said to have lighted up

the whole city of Jerusalem; and during and after which, dancing and singing took place. On each day the trumpets were sounded 21 times. At the end of the seven days' joy, an eighth day of solemn rest was celebrated, which was perfectly distinct from the other days both in its sacrifices and in its general service. The bunch was laid aside, the booths were relinquished, and a sin-offering—in expiation of transgressions that might have taken place during the hilarity of the previous feast-days —was slaughtered.

Three distinct times we find the inauguration of the Temple celebrated on this important festival, by Solomon, Ezra, and Judas Maccabæus, although with regard to the festival itself, it would seem from Nehemiah viii. 17, that it never had been properly celebrated before the Exile. The observances of the booths and the harvest-bunches are still in force with the strict adherents of traditional Judaism, although the agricultural signification of the festival to them can only be a historical or poetical reminiscence. It has been well observed of old, that no festival could have been more apt to inculcate the fundamental principle of Judaism—viz., the equality of all men, than this, which enjoined that every one should live for a time in primitive dwellings, without distinction of rank, or station, or fortune, and should rejoice in the fruits of the last harvest on the hallowed spot, together with the whole people of the land, 'before the Lord.'

TABE'RNÆMONTA'NA. See COW-TREE and FORBIDDEN FRUIT.

TA'BES DORSA'LIS is a term that was formerly used in medicine to designate a series of morbid phenomena, arising from excessive exercise or abuse of the generative functions. Subsequently, it has been used by some writers of eminence as synonymous with *Tabes mesenterica*, or mesenteric disease. Romberg, in his *Manual of the Nervous Diseases of Man*, translated from the German by Dr Sieveking, under the auspices of the Sydenham Society, applies the term to a diseased condition of the spinal cord, giving rise to a diminution or loss of the continuance and vigour of motion and sensation. The first symptom is loss of power of the muscles of the legs, the patient complaining of weakness and inability to perform any movement, or endure any position for a continuance. The sense of touch and the muscular sense are soon found to be diminished. The feet feel numb, and the patient has a sensation as if they were covered with fur. The following symptom is characteristic of this affection. If the patient is ordered to close his eyes while in the erect position, he at once begins to totter and swing from side to side, and it is quite impossible for him to step boldly and firmly forward; he will reel and tumble like a drunken man. The loss of power, after a time, extends to the sphincter muscles. As the disease progresses, the loss of power extends to the arms, the sphincter of the bladder becomes completely paralysed, and the virile powers become extinct. Paralysis of the muscles of the eyeball often comes on comparatively early in this case, and occasions squinting, double vision, and other distressing symptoms. Towards the close of the disease, the patient becomes utterly incapable of holding himself erect or moving; the urine and fæces pass off involuntarily; and bed-sores, terminating in gangrene, often precede death.

The duration of this disease is from six months to ten or fifteen years, but it is often shortened by the intervention of phthisis. It is a disease of middle age, and is for the most part restricted to males.

The disease is one of so hopeless a character that it is almost unnecessary to say anything regarding treatment. Duchenne, who has recently described the disease under the name of *Ataxie locomotrice progressive*, recommends *localised electricity* in the form known as 'Faradisation,' which consists in the employment of the electricity of the induced or secondary current in the helix round the magnet. It should be practised at least three times a week for from five to ten minutes each time, and continued for a month at least.—For the best and fullest account of this disease, the reader is referred to Trousseau's *Lectures on Clinical Medicine*, translated by P. Victor Bazire, M.D., Part i. (Lond. 1866).

TABINE'T, a rich kind of cloth, chiefly used for window-curtains. It consists of a warp of silk and a weft of wool-yarn, of the same kind as that used in making poplin. It has the appearance of a fine damask, and is usually enriched with diaper patterns.

TABLEAUX VIVANTS (i.e., Living Pictures), representations of works of painting and sculpture, or of scenes from history or fiction, by living persons. They are said to have been invented by Madame de Genlis, when she had charge of the education of the children of the Duke of Orleans. They have long been common in theatres, and have more recently become an amusement of private circles. In an æsthetic point of view, they are of no value whatever, but rather are of injurious influence, and contrary to just principles of taste.

TABLE-LANDS, or PLATEAUX, are extensive plains at a considerable elevation above the sea, whose boundaries are either ranges of mountains much higher on the side away from, than on the side next to, the table-lands; or steep acclivities, sloping from the level of the plateaux to the surrounding country. They are often traversed by mountain chains, and occasionally even lose the character of plains altogether, being mere conglomerations of hills. The chief table-lands are—in Europe, Central Spain; in America, the territories of the plains, the great salt plain of Utah, and the north and centre of Brazil; in Africa, the interior of Barbary; while in Asia, almost the whole of the south and centre of the continent consists of plateaux, which rise terrace above terrace till they culminate in that of Tibet. Of the Asiatic plateaux, the principal are: that of Asia Minor (3280 feet above sea-level), Armenia (7000 feet), Persia or Iran (3000 feet), Mysore (4000—5000 feet), Deccan (1500—2000 feet), Tibet (12,000—17,000 feet), and Chinese Tartary (3000—4300 feet). These table-lands are generally accounted for by the supposition of a more extensive and uniform action of the upheaving force than that which produced mountains; and satisfactory indications of the former action being quite recent, and long subsequent to the latter, are occasionally discovered.

TABLE-MONEY is an allowance granted to general-officers in the army, and flag-officers in the British navy, to enable them to fulfil the duties of hospitality within their respective commands. It varies according to the locality or importance of the appointment, £3, 3s. a day being the maximum, except under very unusual circumstances.

TABLE MOUNT. See CAPE TOWN.

TABLES, LUNAR, are tabular lists of the values of the elements of the moon's orbit, as planetary tables are those of the elements of the planets' paths; but the term is also occasionally employed to denote the tabulated angular distances of the moon from certain stars at fixed epochs, as given in the *Nautical Almanac* (q. v.). See LATITUDE.

TABLE-TURNING. See ANIMAL MAGNETISM; SPIRITUALISM.

TA'BOR, a celebrated mountain of Northern Palestine, rising solitarily in the north-eastern part of the plain of Esdraëlon, to about the height of 1000 feet, and commanding the most extensive and probably the most magnificent prospect in the Holy Land. Eastward, the eye catches a gleam of the waters of the Galilean Sea, 15 miles distant; while the whole picturesque outline of its deep-sunken basin, of the rolling trans-Jordanic plateau, and the course of the sacred river itself, is clearly traceable; westward, stretch away into the dim horizon the rich plains of Galilee, rising up into the dark-green ridges of Carmel, overhanging the Levant; on the north and north-east, the snow-covered heights of Hermon (see LEBANON) glitter pale over the intervening hills; while to the south, the view embraces the fatal heights of Gilboa and the confused landscapes of Samaria. T. itself is at present thickly clad with forests of oak, pistacias, &c., the haunt of wolves, wild-boars, lynxes, and various kinds of reptiles. Its beauty alone would be sufficient to insure it distinguished mention among the mountains of Palestine, but it owes its celebrity even more to its having been regarded from an early period as the Mount of Transfiguration. This opinion, however, is now all but universally abandoned, as there is strong evidence of its summit having been then occupied by a city; and travellers are disposed to look for the scene of this supernatural incident further north, in the neighbourhood of Hermon. In the times of the Crusaders, T. was studded with churches and monasteries, relics of which, as well as of Roman and Saracenic structures, still remain.

TA'BORITES (a sect of the Hussites in Bohemia) derived their name from their fortress of Tabor, near the river Luschnitz, an affluent of the Moldau, 49 miles south-south-east of Prague. There is now a small town at the place, which has a pop. of 4300, and carries on some woollen manufactures, &c.—The first leader of the T. was John Ziska (q. v.) of Trocynow. Under him was Nicolas von Hussinecz, who repelled the imperial army from Tabor in 1420. The Calixtines, desirous of the peace of the country, offered the throne of Bohemia first to King Ladislas of Poland, then to the Grand Duke Witold of Lithuania, and afterwards to his brother Coributt. Ziska refused his consent, and thus these parties became completely separated. In the years 1420 and 1421, both of them set forth their creed in a number of articles. The T. absolutely rejected all ordinances of the church not expressly appointed in the Holy Scriptures. Both parties were united by common danger in opposition to a common enemy. In 1422, Ziska defeated the Imperialists at Deutschbrot, and thereafter with uninterrupted success in a number of minor conflicts; and in 1424, Prague was saved from destruction only by submitting to hard terms of peace. After Ziska's death, Procop (q. v.) the Greater, or Procop Rasa (the Shaver), and Procop the Less were their leaders. In 1427 and in 1431, they gained great victories at Miess and Tachau over the mercenary crusaders of the German Empire, and till 1432 their incursions were the dread of the neighbouring countries. The Council of Basel, finding them still unconquered in 1433, proceeded to treat with them; and the Calixtines entered into an arrangement, known as the *Prague Compact*, which, however, was despised by the T. and the Orphans, as that section of the T. who considered Ziska as irreplaceable, had come to be termed. The T. and Orphans were completely defeated at Böhmischbrot on May 30, 1434, by the now united forces of the Roman Catholics and the Calixtines. In the treaty of Iglau, in 1436, the Emperor Sigismund confirmed the compact, and promised religious and political liberty. The civil war, however, continued till King Ladislas in the Diet at Kuttenberg, in 1485, established a religious peace, securing both Roman Catholics and Calixtines in their possessions. The T. were eventually lost in the sect of Bohemian Brethren (q. v.) which arose from amongst them.

TA'BOUR, a small drum, played with one stick in combination with a fife. It was formerly used in war, but has now given place to the kettle-drum.

TABRI'Z (pronounced and frequently written *Tabreez*), a great and ancient city of Persia, capital of the province of Azerbijan, 40 miles east of Lake Urumiah, and on the Aji, which flows south-west into that lake. The town is surrounded by a ditch and a brick wall, pierced by 7 gates. It forms an oblong of gardens and houses, 2¼ miles long; stands 4000 feet above sea-level, but nevertheless has the appearance of being shut in by mountains. The streets are broader and cleaner than in most eastern cities, but they are flanked as usual by the pits from which the earth required for their houses was taken; the houses are infested with noxious insects; and the bazaars are roofed with sticks, and are dark and dirty. Water, however, is comparatively plentiful. The chief buildings of T. are not specially striking. Perhaps the principal architectural feature of the town is the fine ruin, Kabûd Masjid, or 'blue mosque,' about 300 years old, and in part covered with blue tiles beautifully arabesqued. The citadel is a noble edifice of burned brick, the walls of which, however, have been cracked in many places by earthquakes. T. is the seat of a varied industry, in which leather and silk manufactures and gold and silver smith's work alone are of importance; recently it has also become the emporium of an extensive trade, the exact value of which, however, is not known, owing to the careless manner in which the custom-house officials transact their business, and to the prevalence of smuggling. Merchandise, to the value of £400,000, is exported through the regular channels from T. to Russia; but it is estimated that, in 1859, a quantity of equal value was conveyed to that country by smugglers. Since 1859, this illicit traffic has very much diminished, although it still exists along the whole Russo-Persian frontier of Azerbijan. Silk is by far the most important article of export; in 1862, it amounted to 851,925 lbs., value about £393,778. The principal imports are cotton fabrics, dyed, printed, white, and gray, and mostly from English looms, value, in 1862—1863, £815,000; refined sugar, £150,000, chiefly from Holland and France; woollen cloths from Germany, Belgium, and France, and teas (value £42,000). There is little prospect, in the meantime, of any improvement in English commerce at this town.

T., the ancient *Tauris*, became the capital of Tiridates III., king of Armenia, in 297 A.D., and was probably at that time an old city. In 791 A.D., it was enlarged and greatly embellished by Zobaidah, the wife of Harûn-al-Rashid. In 858, and again in 1041, the city was devastated by an earthquake. It was taken and sacked by Timur in 1392, and was soon after seized by the Turkomans, from whom it was taken by the Persians in 1500. In 1721, it was again visited by a dreadful earthquake, and on this occasion 80,000 persons are said to have perished. It has been several times in the hands of the Turks, but was finally taken from them by Nadir Shah in 1730. T. is a city of Turks, and Turkish is the language spoken. Pop. variously estimated at 150,000—200,000.—Eastwick's *Three Years' Residence in Persia* (Lond. 1864), and *commercial Reports from Her Majesty's Consuls* (1864).

TA'BU, TAPU, or TAMBU, a Polynesian term, denoting an institution found everywhere, and always essentially the same, in the Polynesian islands and in New Zealand. Its primary meanings seem to be exactly the same as those of the Hebrew *to'ēbah.* This word, like the Greek *anathema*, the Latin *sacer*, and the French *sacre* (and the corresponding and similar terms in most languages), has a double meaning—a good sense and a bad; it signifies on the one hand, sacred, consecrated; on the other hand, accursed, abominable, unholy. It results from a thing being held sacred, that certain acts are forbidden with reference to it, and from any act being deemed abominable, that it is forbidden; a notion of prohibition thus attaches to the word tabu, and this is, in many cases, the most prominent notion connected with it. The term is often used substantively in the sense of a prohibition, a prohibitory commandment. If a burial-ground has been consecrated, it is tabu; to fight in it is then an act sacrilegious and prohibited, and this also is tabu; moreover, those persons are tabu who have violated its sanctity by fighting in it, and they are, loosely and popularly, said to have broken the tabu. This example illustrates all the uses of the word. It has furnished to the English language the now familiar phrase of being 'tabooed' = forbidden.

The extent to which, among the Polynesians and New Zealanders, things and acts are tabu, must appear almost incredible to Europeans unaware of the facts of savage life. Without much detail, it is impossible to convey any idea of it. The prohibitions, however, divide into two classes: one consisting of traditional rules, binding upon all, acting through religious terror equally upon chiefs and people; the other, of prohibitions imposed from time to time, obviously with the view of maintaining or extending the authority of the chiefs. Those of the first class are by far the most remarkable. Of the most important of them—those bearing upon what are called sacred things, those relating to the person of the chief, and those relating to intercourse between relatives—a few examples may be given.

Any house or piece of ground consecrated to a god is tabu; and thus affords an inviolable shelter to men fleeing from an enemy. *A fortiori*, all temples are tabu. To sit upon or to touch the threshold of a temple, is tabu to all except chiefs of the first order; the lesser chiefs may stride over the threshold, but common persons pass over it on their hands and knees. It is tabu to eat the plant or animal believed to be the shrine of one's tutelary god. To come in the way of a funeral procession is severely tabu, for it is believed that the gods accompany the procession; if any person were to disregard the warning chant of the mourners, they would rush at him and put him to death. Again, to touch the person of a chief, is tabu to his inferiors; also, to touch anything belonging to him, to eat in his presence, to eat anything he has touched, or to mention his name. And a chief's threshold is as sacred as that of a temple, and must be passed over in the same manner. It is strictly tabu to touch a dead chief or anything which belonged to him, or any of the clothes or utensils employed in his interment; even those employed in laying out the body pay the penalty of infringing this prohibition. The interdict upon family intercourse varies in extent in different places. In the Tonga Islands, it was tabu to mention the name of father, mother, father-in-law, mother-in-law; also to touch these relatives, to eat in their presence (unless with the back turned, when constructively the person was not in their presence), or to eat anything which they had touched. In the Fiji Islands, generally, it is tabu for brother and sister, first-cousins, father-in-law and son-in-law mother-in-law and daughter-in-law, brother-in-law and sister-in-law, to speak together, or to eat from the same dish. Husband and wife, too, are forbidden to eat from the same dish. In some places, a father may not speak to his son after he has passed his 15th year. In an immense number of cases, equally extraordinary, the tabu is used to enforce the prevailing ideas of social propriety. It interferes with cooking, eating, dressing, speaking: scarcely anything is too minute to be regulated by it.

The traditional tabu also supplies to some extent the place of laws and a police. In many places, exposed property of some kinds is always under its shelter. In some cases, it appears to have been worked in the interest of the priests; thus, certain foods—for example, turtle—are always tabu, and cannot be eaten until a portion has been set aside for the gods. There is a purely superstitious use of it, too, in relation to common things, as when a canoe is made tabu that it may go more safely.

The chiefs have a large discretionary power of declaring articles or actions tabu; indeed, their power is unlimited, but they are expected to keep within precedent. In many cases, they use it for purely public purposes—thus, when a feast is coming on, they lay a tabu upon pigs and nuts, and other articles, that there may be abundance for the feast. And when a scarcity of anything is apprehended, they place a temporary tabu on its use. Speaking generally, any article of food—fish, flesh, fowl, grain, or fruit—may be rendered tabu. A coast, a river, a hunting-ground, may be declared tabu; and then there is an end of fishing, and sailing, and hunting, until the chief has withdrawn the prohibition. The tabu is obviously a powerful instrument of government; and the chiefs are very adroit in using it for their own advantage.

When a man has accidentally infringed the tabu against touching a chief, or a relative, or things immediately connected with him, he is freed from the state of tabu by a ceremony called *moë-moë;* this consists in pressing, first the palms, then the back of the hands, to a superior chief's foot, and afterwards washing the hands with water. If a man has accidentally eaten food which a relative or chief has left, he goes through a ceremony called *Fota*, which consists in pressing a superior chief's foot against the stomach. Any breach of the laws relating to sacred places, must be atoned for by sacrificing to the offended god. A person, when he is tabu, must not use his hands in feeding himself or in working; were he to feed himself, it is believed that he would die; he must be fed by others until the tabu is removed. In many cases, the tabu can only be removed by time. Thus, a common person, who has touched a dead chief, remains tabu for ten lunar months; a chief for four or five months, more or less, according to the deceased's superiority over him. In several cases, breach of tabu is punished with death; in many, it involves a sort of outlawry—the neighbours of the offender being free to carry off or to destroy his goods.

It is obvious that the effect of breaking a tabu—at anyrate, one effect of it—is to produce uncleanness. The offender has done something unholy, accursed; his hands are not clean; if he has not sinned in the last degree, he must make atonement or undergo purification. The chief, holding a divinely appointed rank, recognised as a semi-divine person, descended from the gods, is the medium of purification; he has authority to loose as well as to bind. The offence consists in a thing having been done displeasing to the supernatural powers, for which, it is believed, they will not fail to take vengeance. It is not, in the general case, an offence against any particular

god; nor is the punishment of it looked for from one god more than from another. Tabu is certainly older than most of the Polynesian gods; it must have existed for ages before the mythologies took their present shapes; it might have existed before any name for god had become current. It has no connection with fetishism. The Polynesians do not worship natural objects; their belief that certain plants and animals are the shrines of gods, would naturally lead to the worship of those; but in fact, they merely do not eat the plant or animal which is the shrine of their tutelary god. And though this is enforced by a tabu, the tabu is evidently distinct from the belief in the god's connection with the plant or animal; it is only the means of enforcing that belief—being the customary means used to prevent any act which would provoke a god to anger. The origin of tabu seems to be a vague fear of superhuman powers; this has become associated with certain things and acts: thus practically, tabu is a system of divinely appointed restraints—religion, in the primary sense of the word. The religious horror has attached itself—or, through the policy of priests and rulers, has become attached—to every prohibition supported by a strong expediency; which it is apt to do among rude peoples, especially where the prohibition relates to the family, or to the relation of tribesmen to their chief. It must have been through a long process of construction, carried on by the governing classes—the chiefs and the priests—that tabu became the system it now is. The extensive political application of tabu is sufficient evidence that the Polynesian chiefs have been adepts in the art of turning the religious feelings of their countrymen to their own account.

TACAHOUT is the name given, in Algiers, by the Arabs to the small gall formed on the Tamarisk tree, *Tamariscus Indica.* Since the discovery of photography, these galls have become of considerable importance as a source of gallic acid, of which they contain a large proportion. The French chemists import considerable quantities; and the same gall, under the name of Mahee, is imported for the same purpose by British chemists from India.

TA'CAMAHAC, or **TACAMAHA'CA**, a name which, from the number of its applications, has produced considerable confusion in the history of commercial products. No less than four different resins are known under this designation. One, from Mauritius, is obtained from a tree common in India and its islands, called the Poon-wood Tree, *Calophyllum inophyllum.* Another, from South America and the West Indies, is obtained from *Zanthoxylum* (*Fagura*) *octandra*—this is usually called Shell Tacamahac. A third, also from South America, is yielded by a tree called *Icica tacamahaca;* it is supposed to be the Mexican Copal. And the fourth is from North America, and is the produce of the Carolina or Tacamahac Poplar; it is collected in small quantities, and has only a small value for supposed medicinal properties. The others are chiefly used for varnishes.

TA'CCA, a genus of plants of a small natural order called *Taccaceæ*, nearly allied to *Araceæ.* They are large perennials with tuberous roots. The species are few, and are found in maritime places and woods in the South Sea Islands and the warmest parts of Asia and Africa. Some of them (*T. pinnatifida*, &c.) are much cultivated for the sake of their tubers, which are used as an article of food, although they are acrid, and require maceration in water to remove their acridity, on account of which also they are generally eaten with vinegar, or some acid substance. They contain a large quantity of starch, which is wholesome and nutritious, and is imported into Britain as a substitute for West Indian arrow-root. It is known as *Tahiti Arrow-root.* Dr Seemann says that it is an effectual cure for dysentery, which other arrow-root is not.—The boiled leaf-stalks of the plants of this genus are also used in China and Cochin-China as an article of food.

TA'CIT RELOCA'TION, in the Law of Scotland, is a phrase borrowed from the Roman law, signifying that when a tenant continues in possession of the lands after his lease or term has ended, there is an implied or tacit renewal of the lease, whereby he continues bound to pay the same rent and observe the same stipulations.—The same doctrine exists in English law, though the above phrase is not used.

TACITU'RNITY, in the Law of Scotland, is a mode of extinguishing an obligation by mere silence, and making no claim upon it within a long time. It is a distinct ground, and embraces a shorter period than the ordinary prescription or Limitation (q. v.); for if a creditor never apply for payment or performance of the obligation, a presumption arises either that there never was such an obligation, or that he has abandoned it. Much depends on the circumstances of each case whether such a doctrine is applicable; and, as a general rule, the periods of prescription are adopted as superseding the common law doctrine of taciturnity.

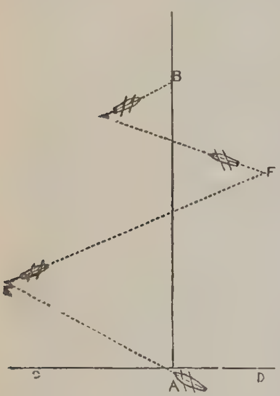
TA'CITUS, Caius Cornelius, the historian. Of his parentage, or of the time and place of his birth, we can only conjecture that his father was probably Cornelius Tacitus, a Roman eques, who is mentioned as a procurator in Gallia Belgica, and who died in 79. From the emperors Vespasian, Titus, and Domitian, he received promotion and other marks of favour; and in 78, he married the daughter of Caius Julius Agricola. In 88, when Domitian was emperor, and T. prætor, he assisted as one of the quindecemviri at the celebration of the *Ludi seculares.* Agricola died in Rome in 83, while T. and his wife were absent; and nothing further is known of the historian till 97, when, in the reign of Nerva, he was appointed consul suffectus, succeeding T. Virginius Rufus, whose funeral oration he delivered. T. had already attained distinction as an orator when the younger Pliny was entering upon public life; and both of them were appointed, in Nerva's reign, in 99, to conduct the prosecution of Marius, then proconsul of Africa. T. became one of the most intimate friends of Pliny, of whose letters 11 are addressed to him. The time of T.'s death is unknown, but he most probably survived Trajan, who died in 117. His extant works are: (1) *Vita Agricolæ*, written after the death of Domitian in 96, and universally admired as a masterpiece of noble sentiment and pregnant epigram. (2) *Historiæ*, written after Nerva's death in 98, and before the *Annales*, and embracing the period from the second consulship of Galba in 68 to the death of Domitian in 96. Only the first four books have reached us in a perfect state, but there must have been many more. (3) *Annales*, commencing with the death of Augustus in 14, and closing with the death of Nero in 68. These also have reached us only in an imperfect state. (4) *De Moribus et Populis Germaniæ.* This treatise is trustworthy only as regards those Germans who were best known to the Romans from their proximity to the Rhine. For the provinces beyond that river, it has no value, whether geographical or political. (5) *Dialogus de Oratoribus*, if the work of T. at all, must be his earliest. T. is one of the greatest of historians. In love of truth and integrity of purpose, he is equalled by few; in conciseness of phrase and power of saying much and implying more in one or two strokes

of expression, he is rivalled by none. The best editions are those of Orelli and Halm.

TACK, the Scottish law-term synonymous with Lease (q. v.).

TACK, TACKING. The *tack of a sail* is the lower windward corner. The *tack* is the rope employed in hauling down that corner to its proper position. The *tack* of a fore-and-aft sail is its lower forward clue or corner; it also designates the rope for hauling down that corner. A ship is said to be on the *starboard* or *port tack* when she is close-hauled with the wind on the starboard or port side.

Tacking is the practice of beating up against an adverse wind by a zigzag course. If a vessel at A require to sail due north to B, and if the wind be either north, or from any point north of the line CAD, it is obvious that the wind will not carry her directly to her destination. As an extreme case, let the wind be north, or dead against her. By setting her sails obliquely, as at A, it will be possible to beat up in the direction AE. If the master consider that at E he has passed sufficiently from his straight course to B, he will then put his helm a-lee, which brings the ship's head straight to the wind, the tacks of the sails being at the same time set free. The after-sails are then smartly braced over to the opposite side, and the ship's head falls off from the wind in an opposite direction to that previously held, until the course is EF. This process is repeated on each side of the line AB, until at length the ship makes her port, B. The length of each tack, as EF, is called a *board*. When the wind is straight ahead, as in the above example, the several boards should obviously be equally on each side of the line AB. If, however, the wind were not so direct, it would be necessary that the boards in one direction should be shorter than those in the other. Sometimes, from the nature of the channel, as an estuary, &c., it is necessary to take a long tack one way, say to starboard, and a very short one to port. This is known as 'sailing with a long and a short leg.'



TACKING OF MORTGAGES, in the Law of England, is a practice that sometimes occurs in the course of mortgage securities, when one person acquires more than one mortgage over the same estate. Thus, though mortgages, according to the general rule, rank according to the order of date, yet, if a third mortgagee, who became so without notice of a second incumbrance, purchase the first mortgage even after notice of the second mortgage, so as to acquire a legal title, and if he holds them both in his own right, he can tack the one to the other, and so obtain priority for the third mortgage over the second mortgage. This is on account of an old technicality, scarcely intelligible to other than lawyers.

TACO'NIC SYSTEM, an extensive series of rocks in the United States, described by Dr Emmons. They consist of two divisions, the Upper having a thickness of 25,000 feet, and containing Lower Silurian fossils; and the Lower, with 5000 feet of thickness, in which, as yet, no fossils have been found, but which is generally considered to be the equivalent of the Cambrian rocks of Britain.

TA'CTICS, MILITARY. Strategy (q. v.) is the art of manœuvring armies with reference to the objects of the whole campaign—the securing of communications, the cutting off an enemy from his base, throwing him into a position where he must fight at a disadvantage, or surrender, &c. Tactics has regard to the evolutions of an army in the actual presence of an enemy. It is the strategy of the battle-field; the science of manœuvring and combining those military units which drill, discipline, and the regimental system have brought to the perfection of machines. It was admirably described by Napoleon as *the art of being the stronger*—that is, of bringing an overwhelming force to bear on any given point, whatever may be the relative strength of the entire armies opposed.

The earliest records of battles are those of mere single combats, in which the chiefs, fighting either on foot or in chariots, performed great deeds; and the commonalty, who apparently were without discipline, were held in profound contempt. With the growth of democracy arose the organisation of the Phalanx (q. v.), the advance of which was irresistible; and its firmness equally so, if charged in front. It, however, changed front with great difficulty; was much deranged by broken ground; and failed entirely in a pursuit, or if attacked in flank. Far lighter, and more mobile, was the Roman Legion (q. v.). Among Roman tactics was also the admirable intrenchment, which they scarcely ever omitted as an additional source of strength for their position.

'Events reproduce themselves in cycles;' and with the decay of Roman civilisation came again the mail-clad heroes and cavaliers—mounted this time on horses—who monopolised the honours of battle, while the undisciplined footmen had an undue share of the dangers. Later in the feudal period, this disparity between knight and footmen was diminished by the employment of bodies of archers, whose shafts carried distant death. The adoption of gunpowder for small-arms altogether neutralised the superiority of the armoured knight. This change brought infantry into the front place in battle, and threw cavalry into the status of an auxiliary. The French revolutionary wars tended much to the development of artillery as a field-weapon, and Napoleon employed this terrible engine to its fullest extent, a practice followed by the best modern generals, who never risk a man where a cannon-ball can do the work. Frederick the Great was considered an innovator for fighting with infantry four deep. During the French War, the formation of three deep became general, and still obtains in several European armies. Before the battle of Waterloo, the British leaders had acquired sufficient confidence in their troops to marshal them in a double line. It is doubtful whether the advance in arms of precision will not soon necessitate the formation in a single line, or even in a single line in open order.

It is impossible, in an elementary article of this character, to give even an approach to an essay on modern tactics, which is an intricate science. We can only notice briefly a few of the more important principles.

First, as to the art of being the stronger, which is undoubtedly the highest recommendation in a general, we may cite the example of the battle of Rivoli. In 1796, Napoleon was besieging Mantua with a small force, while a very much smaller army

operated as an army of observation. The Austrian commander had collected at Trent a force powerful enough to crush completely the French army, with which he was marching south. Parallel with his course lay the Lake of Garda, and to prevent the enemy escaping up one side, as he marched down the other, the Austrian leader divided his army into two powerful corps, and marched one down each side of the lake. The instant the young French general knew of this division, he abandoned the siege of Mantua, collected every available man, and marched against one body of the enemy. Though far inferior on the whole, he was thus superior at the point of attack, and the victory of Rivoli decided virtually the whole campaign. This corresponded in principle with Napoleon's general plan in battle. He formed his attack into column, tried to break through the centre of the enemy's line; and if he succeeded, then doubled back to one side, so as to concentrate the whole of his own force against one half of the enemy's, which was usually routed before the other half of the line could come up to the rescue.

Taken collectively, the tactics of the three arms may be thus summarised: The infantry form the line of battle, and probably decide the day by a general advance over the enemy's ground. The cavalry seek to break the opposing infantry by frequent charges in front, or on any flank which may be left exposed. If a part of the line wavers, a charge of horse should complete the disarray. When the rout commences, the cavalry should turn it by furious onslaught into utter discomfiture. The province of the artillery is to cannonade any portion of the line where men are massed, or where a charge is about to be made; to demoralise cavalry, and generally to carry destruction wherever it can best disconcert the enemy.

Adverting now very briefly to the tactics of the several arms individually, we have—

Infantry.—This force has four formations—skirmishers, line, column, and square. The skirmishers precede and flank an advancing line or column, picking off the enemy, whose masses offer good mark, while their own extended order gives them comparative impunity. If resistance be encountered in force, the skirmishers retreat behind their massed supports. The line is a double or treble line of men, firing or charging. For musketry purposes, it is the most formidable formation, and is the favourite British tactic in every case where the officers can depend on the steadiness of their men. For bursting through a line, the deep column is the most effective. It is the favourite French formation, and during the Revolutionary and Napoleonic wars, the British and Russians alone succeeded in resisting it. At Vimiera, the 50th Regiment, 700 strong, stood in line: it was attacked by a column of 2000 French. The English colonel threw back his left (which was the end attacked), and advanced his right, delivered a volley at point-blank range, charged the column in flank, and utterly routed it before the French could deploy into line to resist the onslaught. The column is therefore the best formation on a march; the line, when in actual collision with the enemy. The formation in Echelon (q. v.) to a great extent combines these advantages. See SQUARE.

Cavalry.—The function of heavy cavalry is limited to the charge in line. The light cavalry form in small sections, to scour the country, collect supplies, and cut off stragglers.

Artillery.—No distinct tactics exist for this arm beyond the fact, that a concentrated fire is vastly the most effective, and that the artillery should always have a support of infantry at hand, to protect it from a sudden incursion of hostile cavalry.

Tactics of position depend on the moral energy of the commander-in-chief. Few would dare as Cæsar did, an invasion in which there was no retreat if defeated. It is a military maxim not to fight with the rear on a river, unless many bridges be provided for retreat, in case of disaster. A convex front is better than a concave front, because internal communication is more easy. The flank should be protected by cavalry, or preferably by natural obstacles. In battle, a long march from one position to another, which exposes the flank to the enemy, is a fatal error. By such, the French won Austerlitz, and lost Talavera. In a pursuit, a parallel line is better than the immediate route the retreating enemy has taken, as supplies will be more readily procured, and he may by celerity be attacked in flank. This was strikingly exemplified in the Russian pursuit of Napoleon's army retreating from Moscow.

TACTICS, NAVAL. With the advent of steam iron-plated ships, and rams, the tactics under which Rodney and Nelson fought and conquered have passed away, while the principles of the new warfare have scarcely been sufficiently established for reduction to theory. A glance at the obsolete tactics of bygone times must therefore suffice in the present article.

In ancient naval engagements, where the vessels fought on the comparatively smooth waters of the Mediterranean, and where the use of oars rendered the commanders nearly independent of the wind, the attack consisted of a charge with the beaked prows, followed, if that failed, by the use of balistæ and a hand-to-hand struggle. See NAVIES, ANCIENT. The introduction of gunpowder, with broadside ordnance, necessitated a change, and the great desideratum of each admiral was to present as long a line of broadsides as possible to the enemy, to take care that none of his ships was masked by the intervention of another between it and the foe, and to endeavour in each ship to oppose its broadside to the bow or stern of a hostile ship, so as to obtain the preponderance of force, and to rake his decks. The ships of two decks and upwards formed the line of battle, while frigates and smaller vessels served as look-outs and skirmishers. A fleet in one line would, however, have been of inconvenient length for sailing, and it was usual to sail in three, six, or nine parallel lines while traversing the ocean, the ships of the rear lines tacking into their places in the line of battle on the signal to form for action. The great principle of manœuvring was to get the weather-gage, i. e., to be to windward of the enemy, both for facility of navigation, and because the smoke would inconvenience him most. The standing attempt during the French war was to double the enemy's line (see CLERK, JOHN, of Eldin) by piercing it, or passing it at the van or rear, and then, by tacking in its rear, to place his ships between two fires. This was first practised in Lord Rodney's action of 1782, and was successfully repeated by Nelson at the battle of the Nile. Under steam, and with ships carrying colossal ordnance, naval tactics have entirely changed. It used to be the object to avoid being raked; it is now to avoid being hit at all. The projectiles used are so tremendous that a few hits involve destruction. Ships are consequently constructed so as to offer the least mark to ordnance; and with the same view, they are kept constantly in rapid motion. Actions are fought, not, as in old time, within pistol-shot, but at a mile or two miles' distance. The loss of life is less; for the battle is no longer decided hand to hand by the cutlass and the boarding-pike, following a furious cannonade;

but after a few long shots with ponderous missiles, one or other vessel becomes disabled, and being helpless, yields the victory to her foe. The ships will be steamed end on if they act as rams, and also to offer less mark to shot. Rival fleets have never yet met on a large scale to fight under the conditions of modern war.

TA'DMOR. See PALMYRA.

TA'DPOLE. See FROG.

TAEL, a money of account in China, is equivalent to about 5s. sterling, or to a thousand of their sole coin, the 'tsëen,' or 'cash.' It is also a weight, and is equivalent to about 1⅓ oz. avoirdupois.

TÆ'NIA, the band over the epistylium or architrave in Doric architecture.

TÆNIA AND TÆNIADÆ. See TAPEWORM.

TÆNIIDÆ, or TÆNIOI'DÆ. See RIBBON-FISH.

TAE-PINGS, the name given to the Chinese rebels who made their appearance in 1850, and (see CHINESE EMPIRE) desolated some of the best cultivated provinces of China. Pekin was taken by the English and French on 12th October 1860. Its capture was followed by the ratification of the treaty of Tien-tsin, which, granting important privileges to European merchants, made it the direct interest of the English, French, and American governments to re-establish order in China. The repulse of the rebels at Shanghai in August 1860 had been followed by several engagements between them and the imperialists, in which they were defeated. Ward, an American, who had taken service under the emperor, and who shewed a remarkable talent for organising irregular troops, had wrought a wonderful improvement in the imperialist army, and he was the chief means of their success. In the beginning of 1862, the T. again advanced on Shanghai, and were twice defeated. In the autumn of the same year, Ward was killed. Some time previously, English officers were permitted, by an order in Council, to take service under the emperor of China; and 'Ward's force,' handed over to an English officer, took the name of Gordon's brigade. Permission was also granted to Captain Sherard Osborne to organise in England a small fleet of gun-boats, to ascend the Chinese rivers and re-establish order. Gordon's brigade rendered essential service to the imperial government. The rebels were defeated in upwards of 16 engagements; and in 1864, almost every important city was taken from them. Captain Sherard Osborne's expedition was less successful. He found that the jealousy of the Chinese officials would not permit him to take the steps necessary to discharge properly the duty he had undertaken, and he therefore threw up his commission, and returned to England. The conduct of the imperial authorities at Su-chow, where a horrible massacre took place, led to the withdrawal of the English military force; but the rebellion had been effectually checked. Towards the end of 1864, the T., however, still offered an opposition to the Imperialists in Kiang-tsu, all the more formidable in consequence of the prevalence of brigandage and insurrectionary movements in parts of the empire not affected by the Tae-ping rebellion. In January 1865, the Mohammedan Tartars of Songaria, on the Siberian frontier, assisted by the free Kirghis tribes, took the town of Tarbagatai and afterwards Kouldja. In the following June a still more serious insurrection broke out in China proper, that of the Nien-fei or rebels of the north, whose special object was to overturn the reigning dynasty. One body of them, in the beginning of 1866, caused serious alarm at Hankow, and would have attacked the European settlement but for the arrival of some English gun-boats. It is believed that the last embers of the Tae-ping rebellion were trodden out in February 1866, when from 30,000 to 50,000 rebels were routed by the imperial army at Kia-ying-chou in Kwei-tung. The victorious general then set out to attack the Nien-fei, or northern rebels, at Hankow, and the imperial troops were several times defeated by them in 1867; but late in 1868 their operations became unimportant.

TA'FFETY (or Taffeta), a term of somewhat general application in silk-mercery. It was formerly applied to all plain silks simply woven by regular alternations of the warp and weft, and is by some writers supposed to be the first kind of silk-weaving known even to the Chinese, from whom it came to us. Modifications have, however, been introduced, by varying the quality of the warp and weft, and by the substitution of various colours for the single one of the original taffety. It has therefore become a sort of generic term for *Plain Silk*, Gros de Naples, Gros des Indes, Shot or Chameleon silk, Glacé, and many others, and even for some combinations of silk wool, and other materials.

TAFFRAIL, in a Ship, is the rail over the heads of the stern-timbers, extending across the stern from one quarter-stanchion to another.

TA'FIA, a name used in the sugar-producing colonies for a kind of rum distilled from molasses. The term is only in general use in French colonies.

TAFILELE'T (or Tafilelt), one of the four territorial divisions of Morocco (q. v.).

TAGANRO'G, an important seaport of South Russia, stands on the north shore of the Sea of Azov, 20 miles north-west of the chief mouth of the Don. It was founded by Peter the Great in 1696, was lost to Russia from 1712 till 1774, when it again reverted to the people who founded it, and since that time it has increased in importance yearly. The port of T. is so shallow that large ships cannot approach within half a mile of the quay, and at this distance from shore they load and unload by the help of barges. The harbour is wholly unprotected. Owing to its position on the shore of a very fertile country, it is able to export wheat in large quantities (933,295 quarters being exported in 1864), as well as linseed, hempseed, skins, wool, butter, iron, copper, and Russian leather. Of these articles, the last four are obtained from the governments of Perm and Orenburg, and are exported chiefly to Turkey, Greece, and Italy. In 1868, 1359 vessels, of upwards of 415,830 tons, entered and cleared the port; and the exports for that year, according to the British consul's report, amounted to £5,877,200; the imports, chiefly wine, agricultural implements, and machinery, tea, fruits, and porter, amounted to £590,464. Pop. 42,304.

TAGLIONI, MARIE, a celebrated *danseuse*, born at Stockholm 23d April 1809, of Italian parents, her father (Filippo T., born at Milan, 1777) having been successively ballet-master at several opera-houses in different parts of the continent. Mademoiselle T. made her début in Paris in 1827, where she created a perfect *furor*, and her position was at once recognised as the first of ballet-dancers. In 1832 she married Count Gilbert de Voisins, and in 1847 retired from the stage, having amassed a large fortune, and afterwards resided in Italy. Died in 1884.

TA'GUS (Span. *Tajo*), the largest river of the Spanish Peninsula, rises on the frontier of New Castile and Aragon, between the Sierra de Albarracin and the Sierra de Molina, about 45 miles north-east of the city of Cuenca. It first flows north-west for about 30 miles to its union with the Gallo, at which point it curves to the south-west, and flows

in that direction to Toledo, whence it flows west to Abrantes in Portugal. From Abrantes the river flows south-west, and passing Lisbon, enters the Atlantic about 10 miles lower down. At Peralejos, a few miles from its source, it is 1 foot deep, 15 paces broad, and confined between rocky walls 400 feet high. At the city of Toledo, it breaks through a romantic rocky pass, the walls of which are upwards of 200 feet high. From Villavelha, 18 miles within the Portuguese border, the T. is navigable to its mouth, a distance of 115 miles. Above Lisbon, the river widens like an estuary, being in some places 5 miles broad; opposite Lisbon, however, it is only one mile broad. The principal affluents are the Jarama, Guadarrama, Alberche, Alagon, and Zezere from the north, and the Guadiela and Rio del Monte from the south. Total length, 540 miles.

TAHI'TI, or OTAHEITE, the chief of the Society Islands (q. v.), is 32 miles long, about 120 miles in circumference, and consists of two peninsulas, connected by an isthmus about 3 miles broad, but which is submerged at high water. Pop. (1862) 13,800, of whom more than 13,000 are natives. The chief town is Papiete, with a safe harbour, a patent slip for vessels of 400 tons, and careening quays. For the trade, history, &c. of T. see SOCIETY ISLANDS.

TAIL, ESTATE, is, in English Law, an estate given to A and the heirs of his body, or A and the heirs-male of his body, or some other class of heirs less extensive than the class of heirs-at-law. It was anciently a question whether in such a case A, the father, could defeat the right of the children, and break the entail. In England, it was early decided that A could, by a sham process, called a fine or Recovery (q. v.), break the Entail (q. v.); while in Scotland a mode of preventing A, or any of his successors, from breaking it, has been legalised since 1685. In all the states of the United States, entail-estates have been declared or have become estates in fee-simple.

TAILOR-BIRD (*Orthotomus*), a genus of birds of the family *Sylviadæ* (q. v.), with a long graduated tail, the feathers of which are narrow. The species are numerous, natives of the East Indies and of the Indian Archipelago, and haunt cultivated grounds,

Tailor Bird and Nest (*Orthotomus longicaudus*).

where they are commonly seen in pairs. Their flight is rapid and undulating, and they seldom ascend above the lower branches of trees. The name *Tailor-bird* is derived from the way in which the nest is formed. Two leaves are taken at the extremity of a twig, and are sewed together by their edges, or a large leaf is sewed together; the necessary holes being made by the bill, and vegetable fibres forming the thread. Within the hollow thus made, a quantity of a cottony substance is placed to receive the eggs.

TAI'LZIE, the ancient term in the law of Scotland to denote a deed creating an entailed estate. See ENTAIL.

TAIN, a royal, parliamentary, and municipal burgh in the county of Ross and Cromarty, on the south shore of the Dornoch Firth, and 24 miles north-north-east of Inverness. There is no proper harbour. The most interesting building is a small ruined chapel, remarkably rude and simple in architecture, and said to date from the 13th c.; and there is also a collegiate church, founded in 1471, and an endowed academy incorporated by royal charter. Brewing and iron-founding are carried on. Pop. of parliamentary burgh about 2500.

TAINE, HIPPOLYTE ADOLPHE, a French critic, was born at Vouziers in Ardennes, 21st April 1828, and studied at Paris, where in 1853 he obtained the diploma of *docteur ès lettres*, for two essays, *De Personis Platonicis*, and *Essai sur les Fables de Lafontaine*. They were followed by his *Essai sur Tite Live* (1854), crowned by the French Academy; *Voyage aux Eaux des Pyrénées* (1855), *Les Philosophes Français du dix-neuvième Siècle* (Paris, 1856), *Essais de Critique et d'Histoire* (Paris, 1857), *Histoire de la Littérature Anglaise* (Paris, 1864), *Philosophie de l'Art* (Paris, 1865; Eng. transl., Lond. 1866); and *Voyage en Italie* (1866). Of these works, by far the most important in itself, and the most interesting to Englishmen, is the *Littérature Anglaise*, in which the author surveys and criticises our whole literature from a point of view which is conceived to be rigorously scientific. According to T., there are three things to be borne in mind when writing the history of a nation's literature: first, the *race* to which the nation belongs; second, its *position* both geographical and in civilisation in the different phases of its literary development; and third, the *period* or duration of these. Under this view, the history of literature assumes the character of a psychological problem, and as such, it is discussed by T., whose speculative ingenuity is as wonderful as the brilliancy and acuteness of his criticism. Every page affords matter for reflection, overflows with the finest eloquence, or sparkles with the keenest wit. Whether or not we agree with the theories and critical *dicta* of the writer, we cannot fail to be struck with their novelty, force, and coherency.

TAI-WAN-FOO, the capital of the island of Formosa (q. v.), on a large alluvial plain on the south-west coast, in lat. about 23° N. It is a large straggling town, contains many park-like spaces with fine trees and green lanes, and is surrounded by a high battlemented wall, six miles in extent. Its chief edifices are the residences of the mandarins and the temples. The commerce of the town was once considerable, but owing to the silting up of the harbour, trade has entirely departed, and no European vessel of the smallest burden can enter the so-called port. Sugar is raised and refined in large quantities in the neighbourhood. The number of inhabitants is not stated, but it is probably large, and certainly decreasing.

TAI-YUAN, China. See SUPPLEMENT in Vol. X.

TALAVE'RA DE LA REY'NA, a town of Spain, in New Castile, in the modern province of Toledo, is charmingly situated on the Tagus, 75 miles south-west of Madrid. It is ancient, straggling, dirty and inconvenient, is surrounded by interesting old

walls, and abounds in antique picturesque fragments. It was formerly a flourishing town; but of its manufactures, only that of silk is now carried on. Fruits are extensively produced in the vicinity. Here, on the 27th and 28th July 1809, Sir Arthur Wellesley, with 19,000 English and German troops, and about 34,000 Spaniards, who, however, with very trifling exceptions, were not engaged, defeated upwards of 50,000 veteran French troops, under Joseph Bonaparte and Marshals Jourdan and Victor. Pop. 7000.

TALBOT, perhaps originally a name equivalent to Blood-hound (q. v.), but afterwards applied to a race of hounds, now extinct, or nearly so, which seem to have been kept for show rather than for use. The T. was of a pure white colour, with large head, very broad muzzle, long pendulous ears, and rough hair on the belly. The White St Hubert Dog was either the T. or a nearly allied breed. The T. is the badge of the ancient House of Shrewsbury (surname Talbot), and the crest of some of the princely Houses of Germany.

TALBOT, WILLIAM HENRY FOX, celebrated in connection with photography, was the son of William D. Talbot of Locock Abbey, Wilts, and was born in 1800. He was educated at Harrow, and afterwards at Trinity College, Cambridge, where he took his degree with honours, and obtained the junior Chancellor's Medal in 1821. In the first parliament summoned after the passing of the Reform Bill, T. sat for Chippenham; but scientific investigation being more to his taste, he gave up politics, and devoted himself to the problem of fixing shadows, ignorant at the time of what had been effected in this department by Wedgwood and Davy. Step by step he discovered for himself a method of obtaining and fixing sun-pictures, and on the dissemination of a report as to Daguerre's successes in the same field, secured his just rights by publishing a paper (*Phil. Mag.* March 1839), in which the successive steps of his investigation and their result were detailed. See PHOTOGRAPHY. This process, by which a *Negative* (q. v.) was primarily obtained, was subsequently improved by his invention (patent dated February 8, 1841) of the Calotype (q. v.) process. Soon afterwards he obtained fresh patents, for an 'instantaneous process' (which seems to have well deserved the name, as by it a legible picture was obtained of a printed bill fastened to the rim of a wheel revolving 200 times per second), a mode of 'photographic engraving,' and a 'polyglyptic process.' His last invention in photographic art was *Photoglyphic Engraving* (q. v.), which was patented April 21, 1858. In 1842, T. obtained the medal of the Royal Society for his previous discoveries. In later years, he devoted himself to the study of general physics; he also occupied himself with the cuneiform inscriptions of the East; and wrote several works, as *Hermes, or Classical and Antiquarian Researches; Legendary Tales; Illustrations of the Antiquity of the Book of Genesis;* and a work on *English Etymologics.* He died September 17, 1877.

TA'LBOTYPE, a photographic process, called by the inventor, Mr Fox Talbot, the Calotype Process (q. v.). Its essential features consist in the production in the camera of an image by light *on* the *surface* of chemically prepared paper, and this distinguishes it from other *paper* processes, and by consequence from other photographic processes.

TALC, a mineral allied to Mica (q. v.), and, like it, easily separated into very thin flakes, which are transparent and flexible, but not elastic, like those of mica. T. is composed almost entirely of silica and magnesia, in the proportions of 57—63 silica, and 30—35 magnesia, with 2—6 water. Its colours are silvery white, greenish white, and green. It has a pearly or semi-metallic lustre, and is unctuous to the touch, in which it differs from mica. It occurs crystallised, generally in hexagonal tables, or in long prisms: the primary form is a rhomboid. It is also found massive, in beds chiefly in micaceous schists, gneiss, and serpentine.—A kind called *Indurated T.*, or *T. Slate*, has a curved slaty structure, and is not separable into laminæ, like common talc. It approaches in character to steatite, and is used for similar purposes.

TALEGA'LLA, a genus of Gallinaceous birds, of the family *Megapodidæ*, having a strong, thick, and very short bill, the upper mandible curved and pointed; the head and neck almost quite naked; the wings short and round; the tail rather long, rounded on the sides; the legs strong, feathered a little below the joint of the tibia and tarsus; the tarsi covered with scales in front; the toes long and strong; the claws large and sharp. The species

Brush Turkey (*Talegalla Lathami*).

are natives of Australia and New Guinea. The best known is the BRUSH TURKEY (*T. Lathami*) of Australia, also known as the WATTLED T. and the NEW HOLLAND VULTURE, the latter name being given to it on account of its naked head and neck, covered in part with fleshy wattles. It is pretty common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavours to escape by running through the thickest *brush*, or by leaping to the lowest branches of a tree, from which it ascends higher and higher, branch by branch. It thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the heat of the day, and although several of a flock are shot, the rest keep their place undisturbed. The T. is generally seen in small flocks, and they make their nests together, the males heaping up, by means of their feet, mounds of several cart-loads of earth and decayed leaves, which are used from year to year, new materials being added every year. The eggs are hatched by the heat of the sun and of the fermenting mound, each egg being separately buried. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, covering them up partially in the mound at night for warmth. The flesh of the T. is excellent, and the eggs are also very delicate and eagerly sought after. It is thought that this bird might easily be added to the list of our domestic poultry.

TALENT (Gr. *talanton*, from a root to balance or

weigh), a word used by Homer to signify indifferently a balance, and a definite weight of some monetary currency. But the weight of money to which Homer applies the term talent was very different from that to which it was applied in later times. Tradition assigns to Pheidon, king of Argos, the introduction of the talent as a standard of money and weight. The *exact* identity of the Æginetan talent with that known as the Babylonian, and generally employed in the East, points to its true origin. It was in all probability introduced into Greece by the Phœnicians, who also introduced a smaller monetary measure and weight, which was by the Greeks known as the Euboic talent. The names Æginetan and Euboic indicate that the talents to which these epithets apply were first used in Ægina and Eubœa; and though, in the East, the larger talent was used for silver, and the smaller for gold, after their introduction into Greece all such distinctive application was soon done away with. The use of the Euboic talent was mostly confined to Athens, Chalcis, and the Chalcidian colonies; while the Æginetan prevailed over the rest of the Greek world. In the 6th c. B. C., Solon introduced at Athens a new talent, which, as the *Attic talent*, succeeded, partly through its superior purity, and partly on account of the greater commercial activity of Athens, in supplanting the other two standards. These several talents were similarly subdivided into 60 minæ, the mina into 100 drachmæ, and the drachma into 6 oboli; and their relative proportions are, Æginetan T. : Euboic T. : : Attic T. : : 30 : 25 : 18, both with respect to their values as weights, and as measures of monetary amount. The following are the values as compared with English standards:

		AS WEIGHT.		AS MONEY (SILVER).
		lbs. avoirdupois.		£ s. d.
Æginetan talent	=	95·	=	406 5 0
Euboic "	=	79·16	=	338 10 10
Attic "	=	57·	=	243 15 0

But by the same decree of Solon, a new commercial talent, of increased weight, was introduced, but only as a weight for goods, not for money.

Talipat Palm (*Corypha umbraculifera*).

TA'LIPAT PALM, or Great Fan Palm (*Corypha umbraculifera*), the noblest palm of the East Indies, a native of Ceylon, Malabar, &c. It grows to the height of 60, 70, or even 100 feet, and has a straight cylindrical trunk, crowned with a tuft of enormous palmate plaited leaves, which are divided near the outer margin into numerous segments, and are united to the trunk by spiny leaf-stalks. The leaves are usually about 18 feet long, exclusive of the leaf-stalk, and 14 feet broad; a single one being sufficient to protect 15 or 20 men from rain. At the age of 30 or 40 years, the tree flowers, and after ripening fruit, generally dies. It produces a long conical erect spadix, rising to the height of 30 feet from the midst of its crown of leaves, and dividing into simple alternate branches, the lower of which sometimes extend laterally 20 feet, the whole covered with whitish flowers, and forming a very beautiful and magnificent object. The fruit is very abundant, globose, and about an inch and a half in diameter. The leaves are used for covering houses, for making tents, and for many other purposes. On occasions of ceremony, every Singhalese noble is followed by an attendant, who carries above his head a richly ornamented T. P. leaf, which is capable of being folded up like a fan, and is then not thicker than a man's arm, and wonderfully light. The leaves of this palm are used in Malabar for writing upon, characters being traced upon them with an iron style. They are prepared for this purpose by boiling, drying, damping, rubbing, and pressing. The soft central part of the stem, pounded and made into bread, has often been of great use in times of scarcity.

TA'LIPÉS, the scientific name for CLUB-FOOT (q. v.). It is derived from the Latin words *talus*, the heel, and *pes*, the foot.

TA'LISMAN (Arabic, but supposed to be derived from the Gr. *telesma*, in the sense of celebration of religious ceremonies), a species of charm, consisting of a figure engraved on metal or stone when two planets are in conjunction, or when a star is at its culminating point, and supposed to exert some protective influence over the wearer of it. The terms Talisman and Amulet (q. v.) are often considered nearly synonymous, but the proper distinctive peculiarity of the former is its astrological character. Talismanic virtues have often been attributed to a peculiarly marked or formed egg, and instances are recorded, by various authors, of eggs hatched with figures of comets or eclipses on them. A species of talisman, which has acquired considerable celebrity, is the Abraxas Stone (q. v.). A species of talisman, at present in use in Asia, is a piece of paper on which the names of the Seven Sleepers and their dog are inscribed. Pasted on the walls of houses, it is believed to be a protection against ghosts and demons.

TA'LLAGE (said by Lord Coke to be from Fr *tailler*, to share or cut out a part), a name which has been sometimes applied generally to subsidies or taxes of every kind, but which, in its more proper and restricted sense, denotes those taxes to which, under the Anglo-Norman kings, the demesne lands of the crown and all royal towns were subject, which were far more rigorous and irregular than the taxes imposed on the gentry.

TALLAHA'SSEE, the capital of Florida, U. S., situated on a high plain, 180 miles east of Pensacola, a well-planned, and so far well-built embryo city. It is celebrated for its salubrious semi-tropical climate, and abundant springs of soft pure water. It is connected by railway with St Marks, 23 miles distant on the coast, and Pensacola. Pop. (1871) 2023; (1880) 2494.

TALLEYRAND-PERIGORD, CHARLES MAURICE DE, Prince of Benevento, the most subtile, shrewd, and unprincipled of all modern diplomatists, was born at Paris, February 13, 1754, of an ancient and distinguished family. His father, CHARLES DANIEL, COMTE DE TALLEYRAND-PERIGORD (b. 1734, d. 1788), was an officer in the French army, and fought all through the Seven Years' War. CHARLES MAURICE being the eldest son, would in all probability have been designed for a military career, had not an accident, which he met with when only a year old, rendered him lame for the rest of his life. He was, in consequence, trained for the church, and studied at St Sulpice, the Sorbonne, and Rheims, but at no period did he

betray the least inclination towards a Christian, or even a moral life. At the age of 20, he came to Paris, and rapidly acquired a reputation for licentiousness. This, however, did not prevent him from obtaining several ecclesiastical benefices, among others, the Abbacy of St Denis, in the diocese of Rheims (1775). Appointed *agent-général* for the clergy in 1780, a lucrative and important post, which brought him into close connection with the heads of the administrative in France, he now began a serious apprenticeship to public business, without, however, pausing in his career of gallantry. So notorious was his *infâme conduite* (as Mirabeau calls it), that, for some years, Louis XVI. shrank from conferring on him further ecclesiastical preferment, and it was only on account of his administrative abilities, that, in 1788, he obtained the bishopric of Autun. When the convocation of the *Etats-généraux* took place, in the year following, he was elected by the clergy of his diocese to represent it, and pronounced in favour of an amalgamation with the *Tiers Etat*, which, on the 17th June, had constituted itself the *Assemblée Nationale*. His attitude and speeches recommended him to the notice of the popular party, and along with Mounier, Sieyès, and Lally-Tolendal, he was appointed to draw up a constitution for the nation. In this capacity, he took an active part in framing the famous Declaration of Rights, and he was one of those selected (after the destruction of the Bastille) to investigate the causes and peculiar features of the revolutionary movement. It was T. who proposed (October 10, 1789) the startling measure for the confiscation of church property, arguing that such property did not really belong to the church, but to the nation, and that if the rights of the existing clergy were secured, the nation, or its representatives, were at liberty to apply it to any purpose they saw fit. On February 13, 1790, a decree for the suppression of religious orders was carried, in spite of a vehement opposition, and three days after, T. became President of the Assembly. He was one of the first among his order to take the oath to obey the constitution (December 28, 1790), and eagerly urged the clergy of his diocese to follow his example. About the same time, he demitted his bishopric of Autun, yet, in the following February, we read of his consecrating two new bishops (those of Aisne and Finisterre), and although denounced in pontifical briefs as a schismatic, declaring his sincere attachment to the Holy See!

Our space does not permit us to describe the important share that T. had in the financial deliberations of this first period of the Revolution, but we must specially note the sagacity he displayed in pointing out the perils attending the issue of assignats, his skill in preparing the way for the adoption of the principle of uniformity in weights and measures, and of an arc of a meridian as the basis of the new metrical system; and above all, the luminous intelligence shewn in the Report which he gave in to the Assembly (September 10 and 11, 1791) upon Public Instruction—a Report conceived in the liberal and comprehensive spirit of the times, and which was undoubtedly the model followed in all the great changes that subsequently took place, when France reorganised her educational system.

In 17*92*, when the old European despotisms were obviously preparing to coerce the young republic, T. was sent to London—but not in an official character —to negotiate with the English government. He did not make a favourable impression on George III. or on Pitt. Thrice, in that year, he essayed to procure a recognition of the republican government, but in vain. The 'September massacres' (see SEPTEMBRISTS) made even the stanchest admirers of the Revolution shudder. Nothing, therefore, could be done; and T. would doubtless have returned to France, had not a letter of M. de Laporte, *intendant* of the civil list of Louis XVI., been discovered, in which T. was noted as a man 'disposed to serve' the king. He was immediately placed on the list of *émigrés*, i. e., proscribed (December 1792); and thus his connection with the Revolution—fortunately, we believe, for his reputation—was suddenly brought to a close. His career as an exile was (as is generally the case) one of hardship and insignificance. He remained in England till forced to leave by the 'Alien Bill,' when he sailed for the United States (February 1794), where he lived for more than a year. After the fall of the Terrorists, he procured the revocation of his banishment; and in March 1796, re-entered Paris, having paved the way for a favourable reception by a series of the most adroit and judicious intrigues. We may first note, *en passant*, that in private life he continued to play the *rôle* of a gay Lothario.

T. attached himself to the *cercle constitutionnel* that gathered round Madame de Staël, and so dexterously did he comport himself, that, in 1797, he was named Minister of Foreign Affairs in place of C. Delacroix. The rise of Bonaparte was a phenomenon which so penetrating a politician as T. could not overlook. He cultivated the friendship of the young general with a sagacious assiduity, keeping him constantly *au courant*, when away from Paris, of the situation of parties, and became his confidant in those designs, the execution of which resulted in the overthrow of the Directory, Brumaire 18 (q. v.), 1799. After this *coup d'état*, the subtle finesse of T. was constantly in requisition. He divined, with a sort of miraculous cleverness, the ideas of Bonaparte, and his whole policy was directed to consolidate the power and authority of his master. In all the diplomatic negotiations that followed the victories of France under the Consulate, he had the principal part; but Bonaparte thoroughly understood his man, and T. was quite conscious, as M. Thiers remarks, that he could never impose on his superior. It was he who proposed the kidnapping of the Duke d'Enghien (q. v.); and it was by his instructions that the crime was consummated, in spite of the vehement opposition of Josephine, whose honest indignation led her to denounce him, as a *maudit boiteux* (cursed cripple). T. took an active part in preparing the way for the establishment of the Empire (1804); and when, in the following year, England, dreading a French invasion, formed a powerful European coalition against France, it was by the ingenuity of T. that it was partially broken up. To him, as much as to Napoleon, was owing the organisation (1806) of the famous *Confederation of the Rhine* (q. v.), which so effectually served the ambitious designs of the emperor. In conducting the negotiations that brought about this Confederation, he exhibited a truly Macchiavellian art. Napoleon was not ungrateful. T. received the principality of Benevento, which he held as an imperial fief.

When the views of the emperor in regard to Spain became apparent, T., who, for more than a year had rather fallen into disfavour with Napoleon, came forward with a plan of his own, which, however, was not adopted; but his presence at the interview between Alexander and Napoleon at Erfurt (1808), proved that his influence was as yet undiminished. The ill success of the Spanish war (at first) induced T. to pronounce against it, and occasioned violent invectives on the side of his sovereign, to which the accomplished cynic (who

retained to the last the manners of the old noblesse) only replied by the sarcasm: '*Quel dommage qu'un si grand homme soit si mal élevé!*' (What a misfortune that so great a man should have been so badly educated!). T. declared in favour of the Austrian marriage; but already the *entente cordiale* between him and Napoleon was ruptured, and he began to look forward to a future in which his own schemes might be hostile to those of the emperor. In a word, he was meditating treachery against the power by which he had risen. The victories of Wellington in Spain, and the reverses of Napoleon in Russia and Germany, widened the breach between them, and T. now only waited the decisive moment in which to ruin the cause of his master. He became the centre of a group of Parisian malcontents, whose influence grew with the advance of the allied armies, and finally, communications were opened up with the latter and with the Bourbons. It was T. who dictated to the senate the terms of the deposition of Napoleon; and on the restoration of the Bourbons, he became Minister of Foreign Affairs in the first government of Louis XVIII. He was also head of the French legation in the celebrated Congress of Vienna; but after the battle of Waterloo, a coldness sprung up between him and the Bourbons, and he was relieved of all his offices. Henceforth, his career is uninteresting to the student of history. He caballed to regain power, but in vain; and during the reigns of Louis XVIII. and Charles X., he was merely a discontented senator, who never lost an opportunity of injuring the court and the government. After the July Revolution, Louis Philippe employed him as ambassador at the English court, where he contrived to bring about a friendly feeling between the new monarchy and the English government. During the brief remainder of his life, nothing externally notable occurred. He died at Paris, 17th May 1838. T. was neither a wise, nor a great, nor a good man; but he was infinitely cunning, dexterous, and supple. He had a larger share than most men of what Carlyle calls 'vulpine understanding;' and if this world had had nothing but knaves and fools in it, the policy and principles of T. might have enjoyed a perpetual triumph; but there were forces in the world, both intellectual and moral, of which he took no account, but which took account of him, and with all his amazing cleverness, dropped him into obscurity and disgrace. T. was an 18th c. sceptic, over whom the Revolution had exercised little influence, while France, and indeed all Europe, had been roused into earnestness by the outburst; and when the ideas of political liberty began their swift, irresistible march, this *diable boiteux* inevitably lagged behind, and sunk out of sight. T. left *Mémoires*, which, however, were not to be published till 1868. For estimates of his character and policy, see the *Mémoires Politiques* of Lamartine; the *Histoire de Dix Ans* of Louis Blanc, where T. is rigorously criticised; the *Mémoires* of Guizot, where he is handled with equal severity and justice; *Notices et Portraits*, by Mignet; and *Vie Religieuse et Politique de Talleyrand* (Par. 1838), by L. Bastide.

TALLICOO'NAH OIL. See CARAPA.

TALLIEN, JEAN LAMBERT, a French Revolutionist, was born at Paris in 1769, and first became notable in the beginning of 1792 as the editor of a Jacobin journal, called *L'Ami des Citoyens*, meant to be a friendly rival of Marat's *Ami du Peuple*. From this date, his influence over the lower orders of the city steadily increased. He was conspicuous in the events of the 10th August, and in consequence received the appointment of secretary to the *Commune Insurrectionelle*. He promoted, and afterwards defended the massacres of September; and on account of his unscrupulous zeal, was elected to the Convention by the department of Seine-et-Oise. There he became the apologist, if not the advocate of Marat, denounced the minister Roland, urged with savage emphasis the condemnation of Louis XVI., and was rabidly eager for the ostracism and annihilation of the Girondists (q. v.). Towards the close of 1793, he was sent to Bordeaux, charged with the mission of destroying every trace of the party he hated. His career in the south-west was a mixture of reckless cruelty and shameful vice. To the odious tyrannies of a proconsul, he added the luxurious profligacy of a satrap. Fortunately for his countrymen, a passion which he conceived for one of his victims, Madame de Fontenay (*née* Cabarrus), led him to pause in his bloody course. He was called to Paris to account for this singular change in his disposition, satisfied his associates (by paroxysms of patriotic vehemence) that it meant nothing particular, and on the 22d March 1794, was chosen president of the Convention. Robespierre, however, had found out the sort of man that T. was. He hated him for his insincerity and immorality, felt instinctively that he could not be trusted, denounced him severely in the Convention, and on the 14th of June got his name erased from the list of members at the Jacobins. T. recognised his danger, and taking advantage of the reaction against the Terrorists (though himself one of the basest of the set), already beginning to shew itself in France, he dexterously rallied the Dantonists, Hebertists, and others against the rigorous government of Robespierre, St Just, and Couthon, and brought about the events of the 9th Thermidor (27th July 1794), which caused the fall of the triumvirate. T. now became for a short time one of the most notable and influential men in France; lent his aid to suppress the Revolutionary Tribunal and the Jacobin Club, and drew up the accusations against Carrier, Le Bon, and others of the Terrorists! But France could not long tolerate this affectation of virtue on the part of one so infamous; his past life was perpetually held up to scorn and reproach; and finally, on the 20th of May 1798, he was forced to leave the Council of Five Hundred. Henceforth, his career is pitiably insignificant. He accompanied Bonaparte to Egypt as *savant* (!), quarrelled with General Menou; and on his return to France, was captured by an English cruiser, and brought to England, where the Whig Opposition was stupid enough to make a hero of him (1801). Soon after, he returned to France, and was contemptuously dismissed as consul to Alicante by Talleyrand, outlived (in utter obscurity) the Empire of Napoleon, and died at Paris, 16th November 1820, supported in his last days by the heirs of the monarch for whose death he had inhumanly clamoured.

TALLOW. See OILS AND FATS.

TALLOW, MINERAL. See MINERAL TALLOW.

TALLOW TREE, the name given in different parts of the world to trees of different kinds which produce a thick oil or vegetable tallow, or a somewhat resinous substance, which, like tallow, is capable of being used for making candles. The T. T. of Malabar (*Vateria Indica*) is a very large tree of the natural order *Dipterocarpaceæ*. It has leathery leaves of 4—10 feet long, and panicles of white, fragrant flowers, with five petals. The stem is often 16 feet in circumference. By incisions in the stem, East Indian copal is got; and by boiling its seeds, there is obtained a firm, white, vegetable tallow, which, as it has no unpleasant smell, is particularly

suitable for making both candles and soap.—The T. T. of China (*Stillingia sebifera*) belongs to the natural order *Euphorbiaceæ*. The capsules are internally divided into three cells, each containing a nearly hemispherical seed, which is covered with a beautifully white vegetable tallow. This the Chinese collect for the manufacture of candles, in order to which, the capsules and seeds are crushed and boiled, and the fat skimmed off whilst in a melted state. To give it a firmer consistency, wax is added to it, in the proportion of three parts to ten of the vegetable tallow. Linseed oil is also added. The candles made of it are beautifully white. This tree has been introduced into North America, is cultivated about Charleston and Savannah, and is almost naturalised in the maritime parts of Carolina. It presents a very beautiful and remarkable appearance at the approach of winter, when the leaves become bright red, and the pericarps falling off, leave the white seeds suspended by threads.—The name T. T. is sometimes given in North America to a species of CANDLEBERRY (q. v.).—The T. T., or BUTTER AND TALLOW TREE of Sierra Leone, is *Pentadesma butyracea*, of the natural order *Guttiferæ*, the fruit of which furnishes a solid oil.

TALLY (Fr. *tailler*, to cut), the name given to the notched sticks which, till a recent period, were used in England for keeping accounts in Exchequer, answering the double purpose of receipts and public records. They were well seasoned rods of hazel or willow, inscribed on one side with notches indicating the sum for which the tally was an acknowledgment, and on two opposite sides with the same sum in Roman characters, along with the name of the payer and the date of the transaction. Different kinds of notches, differing in breadth, stood for a penny, a shilling, a pound, £20, £100, and £1000. The tally was cleft through the middle by the deputy-chamberlain with knife and mallet, so that each piece contained one of the written sides, and a half of every notch; and the one half was retained by the payer as his receipt, while the other was preserved in Exchequer. At the union of England and Scotland, a store of hazel rods for tallies was sent to Edinburgh, but never made use of. Act 23 Geo. III. c. 82 abolished the use of tallies in Exchequer, and the old tallies were ordered to be destroyed by 4 and 5 Will. IV. c. 15. The destruction of the Houses of Parliament by fire in 1834 is supposed to have arisen from the overheating of the flues in which the discarded tallies were being burned.

TALLY SYSTEM is the name given to a mode of buying goods much in vogue among the wives of poor men, whereby they get goods, chiefly articles of dress and cheap finery, on credit, or on terms of payment by small weekly sums till the debt is paid. It, in point of law, gives rise to the following hardships or disadvantages whenever, as is usually the case, the wife, in the absence of, and without the knowledge of, the husband, enters into the contract, and purchases goods which are beyond her station. The husband, when sued in such a case on the contract, can set up a good defence. If he had given his wife sufficient clothes, either in specie or the means of buying them, he is not liable to pay any tradesman who, without his sanction, supplies the wife with more, especially if these are articles of finery. It is only in the case of the articles being strictly called necessaries, that he will be bound at all; and as regards women of the lower classes, a court or jury would construe the word 'necessaries' very strictly in favour of the husband. If the articles are extravagant, and beyond the station of the wife, the husband is then not liable to pay for the price, and no court will compel him to do so. The only ground on which he can be made liable will be, that the husband knew of the purchase, and directly or indirectly sanctioned it; as, for example, by seeing her wear the clothes, and not returning them, or giving immediate notice to the tallyman that he objected to the purchase. Nevertheless, it must be confessed that judges are not uniform in their decisions, and some too easily give effect to the contract, for want of strong evidence on the part of the husband of the earliest disavowal of it he could make. The tallyman generally makes it a stipulation that the bargain shall be kept secret for a certain length of time. Nevertheless, if, when it is discovered, the husband at once repudiates and returns the articles, it is the tallyman's own fault if he is then obliged to take them back after they have been partly used, and he cannot fix the husband with liability.

TALMA, FRANÇOIS JOSEPH, an eminent French tragedian, was the son of a dentist, and was born at Paris, 15th January 1763. He made his *début* as an actor in 1787, at the Comédie Française, where he played the part of Séide in *Mahomet*. He achieved considerable success, but apparently not enough to excite any very high anticipations of his future career, and for upwards of a year he figured only in secondary characters. The first thing that induced the public to notice him attentively was an innovation in the matter of costume when playing the part of Proculus in the tragedy of *Brutus*. Previously, actors had worn the garb of their own country, and even their own time; and Roman senators stalked about the stage dressed as Parisian 'swells' of the 18th century. The absurdity of this fashion forcibly struck T., who set himself to amend it, and in the part referred to appeared in the green-room clothed in a Roman toga, greatly to the astonishment of the company, one of whom (Louise Contat) exclaimed: 'Good God! look at Talma; how ridiculous he is! *Why he has quite the air of an ancient statue!*' The compliment was as exquisite and as just as it was unintentional. Henceforth, a rigorous accuracy in costume became a point with T.; but his first grand triumph in acting was won, 4th November, 1789, when he played Charles IX. in Chenier's piece of that name. During the Revolution, he was in the zenith of his popularity, and made peculiarly his own such characters as Abdelazis, in *Abdelazis et Zuléma;* Othello; Néron, in *Epicharis et Néron;* Pharan, in *Abufar;* and Egisthe, in *Agamemnon.* Exceedingly arrogant and choleric, he was often at strife, either with the public or with some of his fellow-actors. T. was a favourite with Napoleon and Louis XVIII. Some of his later characters were among his best, as Marigny, in *Les Templiers;* Leicester, in *Marie Stuart;* Sylla; Oreste in the *Clytemnestre* of Soumet; Leonidas; and Charles VI. He died 19th October 1826.

TA'LMUD (from Heb. *lamad*, to learn)—i. e., Study, by way of eminence—is the name of the fundamental code of the Jewish civil and canonical law, comprising the Mishna (q. v.) and the Gemara (q. v.), the former as the text, the latter as the commentary and complement. We have spoken under HALACHA and HAGGADA of the gradual development of this 'Oral,' or, chronologically speaking, Post-mosaic Code. We have also there mentioned the older collections upon which the Mishna was framed, and finally redacted in the form in which we now possess it. The oldest codification of Halachoth, or single ordinances, is due to the school of Hillel (q. v.). Simon ben Gamaliel the Patriarch

(166 A. D.) and his school carefully sifted the material thus brought together; and in the following generation, through Jehudah Hanassi (219 A. D.) and his disciples, the work was brought to its close in six portions (Sedarim), 63 treatises (Mesichtoth), and 524 chapters (Perakim), which contain the single Mishnas. A summary of its contents is given under MISHNA. But besides this authoritatively compiled code, there were a number of other law collections, partly anterior to it, and not fully embodied in it, partly arising out of it—as supplements, complements, by-laws, and the like—partly portions of the ancient Midrash (q. v.); partly either private text-books composed by the masters of the academies for their lectures or enlargements of the existing Mishna. All this additional legal material was collected, not rarely together with the dissensions which begot it, under the name of *Boraitoth*, by Chia and his school, in the succeeding generation. Not to be confounded with them, however, are the collections of *Toseftas* or *Great Mishnas*, which, commenced at the time of Jehudah Hanassi himself, and continued after his death by Chija and Hoshaja, embody much of what has been purposely left out in the concise Mishna; that only embraced the final dicta and decisions. Such 'additions' we possess now to 52 treatises, forming together 383 Perakim, or chapters. All these different sources of the 'Oral Law'—finally redacted before the end of the 3d c., though probably not committed to writing until 550 A. D.—belong to the period of from about 30 B. C. to about 250 A. D. This great mass of legal matter, although apparently calculated to provide for every case, if not for all times, was yet found insufficient. The dicta of later masters, the decisions of the courts, the discussions on the meaning and purport of special traditions, the attempts at reconciling apparent contradictions in the received material, the amplifications or modifications of certain injunctions rendered necessary by the shifting wants and conditions of the commonwealth—all these and a number of other circumstances made a further codification peremptory.

We must not omit to state here, that this Mishna (Mathnisin), although it contained nothing but what were indigenous laws and institutions, was yet not a little influenced—if the very fact of its redaction was not indeed caused—by the spirit of the times. At Berytus, at Alexandria, at Rome, the legal schools were then in their most vigorous stage of development, and everywhere system and method were being introduced into what till then had been a vast complex of traditional and popular institutions, decrees, and decisions. The Mishna, in all respects, fulfilled the conditions reasonably to be demanded from such a text-book as it was intended to form; it was clear, concise, complete, and systematic, and, moreover, composed in as classical a Hebrew as still could be written in those days of decadence of the 'sacred language.'

The further development of this Supplementary, Oral, or Second Law, in fact, rather an exegesis thereof, together with the discussions raised by apparent contradictions found in the individual enactments of the Mishnic doctors, is called Gemara Discussion, Complement, or, according to another explanation, Doctrine. Whatever the original meaning of the root (*gamar*), it certainly allows of all these significations. This Gamara contains, apart from the Halacha (q. v.), which is generally written in Aramaic, also a vast number of non-legal, chiefly Hebrew, fragments—homiletic matter, tales, gnomes, legends, and the like—called Haggada (q. v.).

There are two Talmuds, the one called the Talmud of the Occidentals, or the 'Jerusalem' (Palestine) Talmud, which was closed at Tiberias, and the other, the 'Babylonian' Talmud. The first of these now extends over 39 treatises of the Mishna only, although it once existed to the whole of the first five *Sedarim* or portions. Its final redaction—falsely attributed to R. Jahanan (died 279)—probably belongs to the end of the 4th c. A. D.; but the individual academies and masters through whom it received its completion cannot now be fixed with any degree of certainty. There is less discussion and more precision of expression in this than in the second or Babylonian Talmud, emphatically styled 'our Talmud,' which was not completed until the end of the 5th c., and which makes use of the former. As the real editor of the Babylonian Talmud, is to be considered Rabbi Ashe, president of the academy of Syra in Babylon (365—427 A. D.). Both the Mishna and the Palestine Gemara had, notwithstanding the brief period that had elapsed since their redaction, suffered greatly, partly by corruptions that had crept into their (unwritten) text through faulty traditions, partly through the new decisions arrived at independently in the different younger schools—of which there flourished many in different parts of the Dispersion—and which were at times contradictory to those arrived at under different circumstances in former academies. To put an end to these disputes, and the general confusion arising out of them, which threatened to end in sheer chaos, R. Ashe, aided by his disciple and friend Abina, or Rabina (abbr. from Rab Abina), commenced the cyclopean task of collecting anew the enormous mass of Halachistic material which by that time had grown up. The method he pursued was simple enough. His disciples met twice a year at Syra, in spring and in autumn. At the spring gathering, he gave out all the paragraphs of one treatise; and the disciples had the task to find out until the autumn meeting what opinions the different schools had pronounced on the special points thereof. He then investigated the whole critically, and put it into shape according to a certain order. This process took him, with the assistance of ten secretaries, no less than thirty years; and another thirty years were spent by him in the revision of the work, with which he proceeded in the same manner as he had done with the compilation itself. The final close of the work, however, is not due, as generally stated, to R. Jose, his successor at the academy (died 475), but to the school of the Saburaim at the end of the 5th century.

The Babylonian Talmud, as now extant, comprises the Gemara to almost the whole of the 2d, 3d, and 4th *Sedarim* (portions), further to the first treatise of the first, and to the first of the last order. The rest, if it ever existed, seems now lost. The whole work is about four times as large as the Jerusalem one, and its 36 treatises, with the commentaries generally added to them in our editions (Rashi and Tosafoth), fill 2947 folio leaves. The language of the Talmud is, as we said, Aramaic (Western and Eastern), or 'Chaldee,' closely approaching to Syriac. The minor idiomatic differences between the two, are easily accounted for by the different time and place; but the additional matter—quotations and fragments from older Midrash and Gemara collections, Haggada, &c.—is, as before stated, principally written in Hebrew.

The masters of the Mishna (Tanaim) and of the Gemara (Amoraim) were followed by the Saburaim (see above). The code of the Oral Law had come to a close with the second named; and not its development, but rather its proper study, elucidation, and carrying into practice, was the task of the generations of the learned that followed. Apart from this, the Aramaic language itself began to die

out as the popular language, and required a further study. The Saburaim no longer dared to contradict, but only opined on the meaning and practicability of certain enactments, and undertook the task of inculcating and popularising the teachings laid down by their sires: apart from bestowing proper care upon the purity of the text itself, and adding some indispensable glosses. Their activity was at its height in the 8th c., when Karaism (see JEWISH SECTS), which utterly denied the authority of the Talmud, sprang into existence. Respecting, however, this authority of the Talmud itself, there has never been anything approaching to a canonicity of the code, or of a reception of it as a binding law-book by the whole nation. The great consideration in which it was always held is owing partly to its intrinsic value, and to the fact of its becoming the basis of all further development of Jewish literature (it being undeniably the most trustworthy receptacle of the traditional Jewish law), and partly to a prosecution against the Jews in the Persian Empire at the time of Jesdegerd II., Firuz, and Kobad, who closed the schools and academies for a space of nearly 80 years, during which this book was the sole authoritative guide of public conscience, and remained endowed with its importance even when the schools were restored. The best commentaries of the Mishna are by Maimonides and Bartenora; of the Babylonian Talmud by Rashi (q. v.) and the *Tosafists* of France and Germany. An abstract of the Talmud for practical (legal) purposes by Maimonides (q. v.) is called Mishne Thorah. The Mishna was first printed at Naples, 1492; the Talmud of Jerusalem at Venice about 1523. The Babylonian Talmud was first published at Venice in 1520. It is generally printed in twelve folios, the text on the single pages being kept uniform with the previous editions, to facilitate the references. No translation of the Gemara has ever been carried further than a few single treatises. The complete Mishna, on the other hand, has been translated repeatedly into Latin, German, Spanish, &c., by Surenhus, Rabe, Jost, and others. We must refrain, in this place, from attempting a general characterisation of the Talmud, a work completely *sui generis*. It will assuredly some day, when properly investigated, prove one of the most important records of humanity. Nothing can give even an approximate idea of the immensity of material, historical, geographical, philological, poetical, that lies hidden in its mounds. A contribution to the records of fanaticism may also be found in the 'exoteric' history of the Talmud, which was, albeit utterly unknown save by a few garbled extracts, prohibited, confiscated, burned, and generally prosecuted and inveighed against by emperors, popes, theologians, and fanatics generally, from Justinian down almost to our own day, as perhaps no other book has ever been. In our own times, however, its value begins to be recognised by great scholars, not merely as the only source of the knowledge of Judaism, but as the chief source—next to the gospels—even for the history of the origin and early days of Christianity; a notion long ago hinted at rather than pronounced by eminent divines like Lightfoot and others. See also JEWS (*Jewish Literature*), MIDRASH, MISHNA, HALACHA, HAGGADA. See a remarkable paper on the *Talmud*, in the *Quarterly Review* for 1867.

TA'LPIDÆ. See MOLE.

TALUS, a term employed in Geology, to designate the sloping heap which accumulates at the base of a rock or precipice, from fragments broken off by the weather, or materials in any way carried over it. The term is also applied to the slope of a wall which diminishes in thickness as it rises.

TAMA'RA SPICE, a favourite mixture of condiments used by the Italians. It consists of powdered cinnamon, cloves, and coriander seeds in equal parts, and half the same quantity of aniseed and fennel-seed powdered.

TA'MARIN (*Midas*), a genus of South American monkeys, small and beautiful, with short muzzle, prominent forehead, long nails, which, except on the hinder thumbs, are formed like claws, the tail longer than the body, not prehensile, and covered with hair so as to resemble the tail of a squirrel. The SILKY T., or MARAKINA (*M. rosalia*), is the best known of the genus. It is of a golden yellow colour, with fine silky hair, of which it is exceedingly careful, to keep it free from stain. It is often brought to Europe, but is very tender, and seldom lives long. It is a very gentle and playful creature. The hair of the head and neck is elongated, so as to form a wig or mane; but this character appears far more strongly in the LITTLE LION MONKEY (*M. leonina*), which inhabits the eastern slope of the

Little Lion Monkey (*Midas leonina*).

Cordilleras, and of which, although it is a very small animal, not many inches long, the appearance is an amusing caricature of that of the lion.

TA'MARIND (*Tamarindus Indica*), a beautiful tree, of the natural order *Leguminosæ*, suborder *Cæsalpineæ*, a native of the East Indies, but now very generally cultivated in warm climates. Only one species is known (*T. Indica*), a spreading tree, 30 or 40 feet high, with alternate pinnate leaves which have from 12 to 15 pair of small leaflets, and fragrant flowers, with three petals, the pods brown and many-seeded, as thick as a man's finger, and about six inches long. The pods are filled with a pleasant, acidulous, sweet, reddish-black pulp. It is brought to Europe, mixed with seeds and fibres, in the form of a mass resembling jam, from the East and West Indies, and the Levant. Tamarinds are generally preserved by throwing hot syrup on the ripe pulp; but a better method is to put alternate layers of tamarinds and sugar in a stone jar, the colour and taste being thus more like those of the fresh pulp. The wood of the T. tree, and especially of its roots, is a cabinet wood of much beauty, but of extreme hardness, so that it is wrought with difficulty.—The pods of some other trees of genera allied to *Tamarindus* are filled with a similar pulp, which is used in the same way, as the T. Plum of India (*Dialium Indicum*), and the Brown and Velvet Tamarinds of Sierra Leone, species of *Codarium*.

On chemical analysis, tamarind pulp is found to contain citric, tartaric, and malic acids; potash, sugar, vegetable jelly, &c. As a salt of copper is a common adulteration, a piece of polished iron (a

knife, for example) should be plunged into the pulp, and left in it for an hour, when, if copper be present, it will be deposited on the iron. Tamarind pulp is refrigerant and gently laxative; and in combination with more active remedies, is often employed in the diseases of children. It is used in India as a cooling article of food, and a kind of sherbet is also formed from it; it is also an excellent addition to curries. Tamarind tea is made by infusing tamarinds in boiling water; when cold, it forms an agreeable and cooling drink in inflammatory or febrile disorders. Tamarind whey is prepared by boiling one ounce of tamarinds with a pint of new milk, and straining: this also is an excellent cooling drink in similar cases.

TA'MARISK (*Tamarix*), a genus of plants of the natural order *Tamaricaceæ*. This order contains rather more than forty known species, all natives of the warmer parts of Europe and Asia, and of Africa, generally growing in arid situations. Some of them are herbaceous, others are shrubs or small trees, with rod-like branches, scale-like leaves, and small flowers in close spikes or racemes. The calyx has four or five segments; the corolla four or five petals; the stamens are hypogynous, equal in number to the petals, or twice as many; the pistil has three styles; the fruit is a one-celled capsule, with numerous hairy seeds. The COMMON T. (*T. Gallica*) grows in sandy places in the countries near the Mediterranean, and has been naturalised in some places on the southern coasts of England. It sometimes attains a height of 30 feet. The twigs seem to possess tonic properties, and their medicinal virtues were once in high repute. The ashes of this and some other species of the genus contain much sulphate of soda.—The ORIENTAL T. (*T. orientalis*) is one of the few trees to be seen in the Arabian and African deserts, with the sands of which it seems to struggle more than any other tree or shrub. Its leafless appearance accords with the surrounding desolation. It is called *atlé* or *ethel*, and its wood is used both for fuel and for many economical purposes. —Galls are found on some species in India, and are valued both for medicinal use and for dyeing. *T. mannifera*, perhaps a variety of *T. Gallica*, yields the kind of Manna (q. v.) known as Mount Sinai manna.—The GERMAN T. (*Myricaria Germanica*) belongs to another genus of this order. It is a smaller shrub than the Common T., and abounds in many parts of Europe and Asia, although not found in Britain. It was formerly supposed to possess valuable medicinal properties, but is now little regarded.

Common Tamarisk (*Tamarix Gallica*).

TA'MBOUR (Fr. *tambour*, drum), a frame upon which muslin or other material is stretched for embroidering. The tambour frame originally was made round. Tambour-work was extensively employed for the decoration of large surfaces of muslin, &c., for curtains and similar purposes; but pattern-weaving has been brought to resemble it so closely, that it is being rapidly superseded.

TAMBOUR, in Fortification, is a small work, usually a timber stockade, about 6 feet high, and loopholed. Its object is to defend a gateway, the road into a village, or to afford flanking fire on a bridge, &c. The tambour on the covered-way is the traverse which closes an entrance from the glacis.

TAMBOURI'NE, a very ancient musical instrument of the drum species, much used by the Biscayan and Italian peasants at their festivities, and sometimes introduced into orchestral music where the subject of the piece is connected with a people who use it, as the Basques, gipsies, or peasants of the Abruzzi. It is composed of a piece of parchment, stretched on the top of a hoop furnished with little bells, and is sounded by the hand, fingers, or elbow. When sharply struck by the hand, the tambourine has not much effect, unless used in numbers. When sounded by gliding the fingers along the parchment, a roll results, in which the bells are chiefly heard; and by rubbing the parchment, without quitting it, with the whole weight of the thumb, the instrument gives out a wild, grotesque sound, which is sometimes of service in masquerade scenes.

TAMBO'V, a government in the south-east of Great Russia, bounded on the E. by the governments of Penza and Saratov. Area 25,542 sq. m.; pop. 1,974,584. The southern districts are hilly; the interior is a somewhat elevated plateau, with a gradual slope toward the north. Several lakes are found in the north of the government, and the principal streams are the Tsna, an affluent of the Moksha, and the Moksha, which is itself an affluent of the Oka. The climate of T., owing to its exposure to the biting north winds, against which there is no protection, is more severe than in neighbouring governments. The soil in the central and southern districts is a rich vegetable mould, and is very productive. In the north, clay predominates, and requires much manure. The chief agricultural products are rye, wheat, buckwheat, oats, hemp, and flax. The larger forests are found in the north, and pasture-lands extend for the most part along the banks of the rivers. Agriculture and cattle-breeding are the principal employments; and some of the breeds of oxen, sheep, and horses are excellent. Cloth, distilled liquors, tallow, and iron are the chief manufactures. The products of the government are exported largely by the Tsna and the Moksha to the Oka and Volga.

TAMBOV, capital of the government of the same name, on the Tsna, 750 miles south-east of St Petersburg. It was founded in 1636 under the Czar Michael Theodorovitch, and served as a fortress against Tartar invasion. It is regularly built, and, though the houses are mostly of wood, there are several important institutions, as the college, the military hospital, &c. T. is the seat of considerable manufacturing trade, there being in all 28 factories, in which cloth and sailcloth are extensively made. The chief articles of trade are leather, wool, tallow, and salt beef. Pop. 29,356.

TAME ANIMALS, in point of law, render their owners subject to certain liabilities. There is no restriction as to what wild animals may be tamed; and the person who tames one, and retains possession, becomes the owner of it. There is, however, in all such cases an obligation on the owner

to keep the animal with due care; and if it tends to be a nuisance to a neighbourhood, he would, in extreme cases, be liable to an indictment, or in most cases, to an action of damages. If the animal tamed is naturally ferocious, then it is incumbent on the owner to keep it secure, so as not to allow it an opportunity of doing mischief; and in case of accidental escape, it is seldom that a jury will be persuaded that the owner is not guilty of negligence, and liable for the damage done. There is a certain class of animals which may exist in a wild state, yet by long use, or a second nature, have become domesticated, such as dogs and cats, and are called *mansuetæ naturæ*, in contradistinction to ferocious animals, such as lions. With regard to animals *mansuetæ naturæ*, the rule is, that the owner is only liable for mischief done by such animals when he has been guilty of some negligence in keeping such animals; and in practice this amounted to saying, that, if the owner was ignorant that the animal had once before done similar mischief, he would not be liable, unless he had omitted to take some care to restrain that evil propensity. Thus, if a dog or cat, from some sudden whim, chose to attack some person, or other animal, not being incited to it by the owner, such owner is not at common law liable for the first offence; but in case of a second offence, he was generally held liable, at least whenever there was evidence of slight negligence superadded. Hence, if a dog worried sheep casually, the owner was held to be not liable, if it was the first offence. This state of the law was, however, found to work harshly, and a statute passed first for Ireland, then for Scotland, and lastly for England, the effect of which is to make the owner of a dog liable for damages caused by its worrying sheep, even though it is the first offence, and though the owner was not guilty of any negligence. These statutes passed in 1862, 1863, and 1865 respectively, and they establish an exception to the general rule, which still is in force, as to mischief done by dogs, other than worrying sheep—namely, that before the owner can be made liable, it must be proved that he knew of the dog or cat's mischievous propensity to do the act in question, and did not use due care in restraining it. This is the rule where, for example, a dog bites a person, or a bull gores a passenger. In short, negligence is the gist of the action, and more than mere ownership must be proved against the owner. Sometimes owners of lands plant spring-guns, traps, and similar implements, with a view to kill dogs, cats, and other vermin straying in such fields. The practice of placing spring-guns and man-traps, with a view to kill poachers, was found once to prevail, and created a great outcry about forty years ago; and the legality of the practice was questioned, but the judges in England held, that if the man injured was a trespasser, the owner of the land was not liable; consequently, a statute was passed to make it illegal in future to place such engines, except in, and close to, dwelling-houses. In Scotland, the judges held that the practice was illegal at common law, and no statute was necessary. But though man-traps put in fields are now illegal, traps which destroy dogs or cats are not so, with this qualification, however, that the traps must not be put near a highway, where the dog or cat might be lured aside when lawfully passing, as this would be taking too great an advantage of the instincts of the animal. As regards the stealing of tame animals, it was a technical defect in the common law of England that the offence of larceny could not be committed upon them; but by statutes, it is provided that in most cases the offence of stealing or destroying tame animals is punishable either by fine or by imprisonment, in much the same way as larceny is punishable.

TAMERLANE. See TIMÛR.

TAMIL′ (more properly spelled *Tamir′*, but erroneously written *Tamul*, and erroneously termed by the earlier Europeans 'the Malabar') is the name of the language earliest cultivated of all the idioms which the Rev. R. Caldwell designates as Dravidian—this term comprising, according to him, besides the Tamil, the Telugu; Canarase; Malayâlam, or Malayârma; Tul′u, or Tul′uva; Toda, or Tuda, or Tudava; Kôta; Gônd; and Khond, or Kund, or Ku. 'The Tamil language,' this learned author says in his *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, 'is spoken throughout the vast plain of the Carnatic, or country below the Ghauts, from Pulicat to Cape Comorin, and from the Ghauts, or central mountain-range of Southern India, to the Bay of Bengal. It is also spoken in the southern part of the Travancore country, on the western side of the Ghauts, from Cape Comorin to the neighbourhood of Trivandrum; and in the northern and north-western parts of Ceylon, where Tamil′ians commenced to form settlements prior even to the Christian era, and from whence they have gradually thrust out the Singhalese. All throughout Ceylon, the coolies in the coffee-plantations are Tamil′ians; the majority of the money-making classes even in Colombo are Tamil′ians; and ere long, the Tamil′ians will have excluded the Singhalese from almost every office of profit and trust in their own island. The majority of the domestic servants of Europeans, and of the camp-followers in every part of the presidency of Madras being Tamil′ people, Tamil′ is the prevailing language in all military cantonments in Southern India, whatever be the vernacular language of the district; hence, at Cananore, in the Malayâla country; at Bangalore, in the Canarese country; at Bellary, in the Telugu country; and at Secunderabad, where Hindustani may be considered as the vernacular, the language which most frequently meets the ear in the bazaar is the Tamil′. The majority of the *Klings*, or Hindus who are found in Pegu, Penang, Singapore, and other places in the further east, are Tamil′ians. . . . . Including Tamil′ians resident in military stations and distant colonies, and the Tamil′ian inhabitants of South Travancore and Northern Ceylon . . . . the people who speak the Tamil′ language may be estimated at *about ten millions*.' 'Tamil′ includes two dialects, the classical and the colloquial, or the ancient and the modern, called respectively the Shen-Tamil′ and the Kod′un-Tamil′.' The former is the language of poetry and of the ancient inscriptions; it contains fewer words borrowed from the Sanscrit than the colloquial Tamil′, and among these chiefly such as express abstract ideas of philosophy, science, religion, and technical terms of the more elegant arts; and, in general, it so considerably differs from the colloquial Tamil′ that it is almost unintelligible to the unlearned Tamil′ian. Of all the Indian languages, Tamil′ has the most imperfect alphabet. The latter consists of 12 vowels—viz., *a, â, i, î, u, û, e, ê, o, ô, âi*, and *au*—and of 18 consonants—viz., *k, ch, t′, t, p, R, ng, ñ, n′, n, m*, a final *n, y, r, l, v, r′, l′*. Compared to the Devanâgarî alphabet of Sanscrit, it is deficient therefore in the vowels *r′i, r′î*, and *lr′i*, though it possesses a short *e* and a short *o*, which the Devanâgarî has not; it has but one sound for *k, kh, g, gh*; for *ch, chh, j, jh*; for *t′, t′h, ′d, ′dh*; for *t, th, d, dh*; and for *p, ph, b, bh*. It is destitute, moreover, of the Sanscrit aspirate *h*, of the Sanscrit sibilants, *s, s′* and *sh*, and of Anuswa′ra and Visarga. Of combined consonants, which abound in the Devanâgarî

alphabet, it admits only the junction of the nasal and the mute, as *n-t*, *n'-t'*, &c.; doubled nasals, as *n-n*, *m-m*, &c.; doubled surds, as *k-k*, *ch-ch*, &c.; also *t'k*, *t'p*, *Rk*, *Rch*, *Rp*, *yy*, *ll*, *vv*, and *nR*; of triple consonants, only *r'nd* and *ynd*. If Sanscrit derivatives, therefore, are Tamil'ised, various devices are resorted to in order to separate Sanscrit groups of consonants. Thus, Sanscrit *pra* becomes Tamil' *pira*; Sanscrit *kr'ishn'a* becomes Tamil' *kirut't'ina-n* or *kit't'ina-n* (*t't* instead of *sh*).

The earliest history of the Tamil' country is still involved in obscurity. From evidence afforded by the language, Dr Caldwell has drawn a sketch which would tend to shew that the un-Aryanised Tamil'ians had 'kings,' who dwelt in 'fortified houses,' and ruled over small 'districts of country;' that they had 'minstrels,' who recited songs at festivals; but that they were without 'hereditary priests,' without 'idols,' and ideas of 'heaven, hell, soul, or sin;' yet that they acknowledged the existence of God, whom they styled *kô*, or king, and erected to his honour a temple which they called *kô-il*, or God's house. Their chief worship, however, seems to have consisted in bloody sacrifices which they offered to 'the devil.' Dr Caldwell further shews that they were acquainted with the ordinary metals, except tin and zinc, and with the planets known to the ancients, except Mercury and Saturn; that they had medicines, hamlets, towns, ships, and practised the necessary arts of life, such as cotton-weaving and dyeing, though none of the arts of the higher class, as painting, sculpture, &c.; that they knew no astronomy, and were ignorant of philosophy and grammar. The earliest civilisation of the Tamil'ians is traditionally attributed to the influence of successive colonies of Brahmans from Upper India; and the leader of the first colony is said to have been the Rishi (q. v.) or saint *Agastya*, a personage who plays an important part in Brahmanical legends. He is called the first king of the Pândîya kingdom, which was situated near the southern extremity of the peninsula; and by the majority of orthodox Hindus he is believed to be still alive, though invisible to ordinary eyes. His era is supposed to belong to the 6th c. B. C.; though, like all other ancient Hindu dates, this date, too, cannot be fixed with any degree of certainty. Whether the Vedic worship (see VEDA) was ever known in the Tamil' country, may be matter of doubt; the worship introduced by the Brahmans seems, on the contrary, to have been that based on the incarnations of Vishn'u (q. v.) and S'iva (q. v.), and therefore to belong to an advanced stage of Hinduism. Vaishn'avas, S'aivas, and S'âktas (see INDIA) are the now prevalent sects of the Tamil' country; for the Jainas (q. v.), who flourished in the Pândîya kingdom, probably from the 8th or 9th c. to the 12th or 13th after Christ, were finally expelled from it; and only a few adherents of this sect may now be met with there.

The oldest Tamil' works are, however, those written, or claimed to have been written, by the Jainas; and it is a remarkable fact, that at any period of Tamil' literature few Brahmans have contributed anything to it that may be deemed worthy of preservation. The finest composition which Tamil' possesses is the *KuRal'* of Tiruval'l'uvar, 'a work consisting of 1330 distichs or poetical aphorisms, on almost every subject connected with morals and political economy.' Dr Caldwell holds that it is not later than the 9th c. after Christ. A commentary on this work by Parimelar'agar is the most classical production which has been written in Tamil' by a Brahman. Besides the *KuRal'*, the following works are said to have received the sanction of the Madura College, which, according to tradition, founded by Vam's'a S'ekhara for the cultivation of the Tamil' language and literature, was then probably the most celebrated seat of learning in all Hindustan. Their names are: *Naladiyar*, *Nanmanikkadikai*, *Iniyavai Narppatu*, *Inna Narppatu*, *Kar Narppatu*, *Kallavali Narppatu*, *Tokai*, *Tirikadukam*, *Asara Kovai*, *Pala Moli*, *Siru Pansa Mulam*, *Mutu Moli Kanji*, and *Elati*. For a list of other and later works written in Tamil', both medieval and modern, embracing the topics of Religion—Protestant theology, Roman Catholic theology, Hinduism, and books published by Mohammedans—Jurisprudence, Philosophy, Science, Arts, Literature, Philology, Geography and History, Periodicals and Newspapers, see the very useful *Classified Catalogue of Tamil' printed Books, with Introductory Notices*, compiled by John Murdoch (Madras, 1865); and for learned purposes, the invaluable *Comparative Grammar of the Dravidian or South-Indian Family of Languages*, by Rev. R. Caldwell (Lond. 1856).

TA'MMERFORS, a town in the south of Finland, 250 miles (direct line) west-north-west of St Petersburg. It is situated on a rapid which connects two lakes, and affords motive-power to the extensive cotton-mill of Messrs Notbek & Co., in which 30,000 spindles and 550 looms are in constant operation, and 1566 persons are employed. Pop. 5538.

TA'MMUZ, a word which occurs once in the Bible—viz., Ezek. viii. 14: 'And, behold, there sat women weeping for Tammuz.' The derivation of the word is as problematic as is the meaning itself. The Vulgate (all the other versions give the word unchanged—thereby confessing the universal ignorance on the subject) has Adonis, and this has indeed been accepted as the most credible explanation of this strange name. It probably means the Phœnician god Adonis, whose chief temple and worship was at Byblus, but who at an early period had been introduced into Syria, Cyprus, and Greece, where he was connected with Aphrodite. His festivals were partly the expressions of joy, partly of mourning. In the latter, the women gave themselves up to the most unmitigated grief over the 'lost Adonis,' shaved off their hair, and sacrificed their chastity in his temples. The days of mourning were completed by a solemn burial of an image of the god. This period was followed by a succession of festive and joyful days, in honour of the resurrection of Adonis. The river Adonis (Nahr Ibrahim) (see PHŒNICIA), which once a year 'ran purple to the sea' from the Lebanon, was supposed to be tinged by the blood of the god; and a vessel sent off from Alexandria, and carried by the tide to Byblus, used to inform the mourners by letter that he had been found again. There is no doubt that the different phases of the year, or rather the disappearance and reappearance of the enlivening rays of the sun, and their influence upon all nature (see OSIRIS), were symbolised in these originally poetical, afterwards licentious and fanatical rites. The time of the year at which these feasts were celebrated, has given rise to much dispute. Most probably, they took place at the summer solstice, and the designation of a Hebrew month as Thamuz—which falls about our August—seems further to favour this opinion.

TAMMY, a thin worsted stuff, highly glazed. It is much used for ladies' boots, under the name of *Lasting*; it is also called *Durant*. It is also used, undyed, to form sieves for use in cooking, to strain sauces. Such sieves are called Tammies, or Tamis.

TAMP, TAMPING. See MINES and BLASTING.

TAMPAN, a Tick (q. v.) of South Africa,

remarkable for its very poisonous bite, found in Angola and the country southward from it, and described by Livingstone in his *Travels.* It attacks by preference the parts between the fingers or toes. It attains the size of a pea, and when it has satiated itself with blood, is of a dark-blue colour, and its skin so tough, that it cannot be burst by squeezing with the fingers. The first effect of the bite is a mingled sensation of pain and itching, which ascends the limb until it reaches the abdomen, and soon causes either violent vomiting and purging, or fever. The tingling sensation lasts for a week.

TAMPI'CO, or Santa Anna de Tamaulipas, a seaport of Mexico, in the state of Tamaulipas, on the Panuco, 5 miles from its mouth in the Gulf of Mexico. Its streets are broad and regular, and among other institutions it contains a custom-house. At the mouth of the river is a dangerous bar, and the harbour is unsafe. Hides, tallow, bones, and salted meat are exported to Great Britain and the United States. In 1864, the imports amounted to £668,404; the exports—greatly reduced within recent years by the state of anarchy and confusion into which the country has been plunged—to £235,473.

TA'MPION, the wooden plug placed in the mouth of a piece of ordnance to preserve it from dust and damp.—In Naval Gunnery, the tampion is the wooden bottom for a charge of grape-shot.

TAM-TAM, an Indian musical instrument, resembling the Tambourine (q. v.), but larger and more powerful, and oval instead of round. It has been occasionally introduced into orchestral bands.

TAMUS. See BRYONY.

TA'MWORTH, a parliamentary and municipal borough, partly in the county of Stafford, partly in that of Warwick, at the confluence of the Tame and Anker, 7 miles south-east of Lichfield. Of the ancient church, the transepts are Norman; the remains of the ancient castle, to which modern additions have been made, are in various styles. Brickmaking, brewing, dyeing, wool-stapling, and manufactures of tapes and small wares are carried on. There is a bronze statue to the late Sir Robert Peel, erected in 1852. Pop. (1881) of municipal borough, 4888; of parliamentary borough, 14,098.

TA'NAGER (*Tanagridæ*), a family of birds related to the Finches (*Fringillidæ*), having a conical beak,

Tanager (*Pyranga rubra*).

triangular at the base; the upper mandible notched towards the tip, and its ridge arched. The species are numerous, and the Linnæan genus has been divided into a number of genera, all of which possess the characters just given, and popularly receive the name Tanager. All of them are American, and most of them belong to warm regions; but some visit more northern parts of America as birds of passage. Many of the tanagers are birds of very beautiful plumage, and many have good powers of song. The ORGANIST T. (*T.* or *Euphonia musica*) is particularly famous for its rich full tones.

TANANARIVA'. See ANTANANARIVA.

TAN-BALLS. A useful way of utilising the spent bark of the tanner's yard has been adopted in many parts of England: it consists in pressing the bark into balls or lumps, which harden on drying, and serve for fuel.

TANCRED, a Sicilian prince, the son of Eudes, a Norman baron, and of Emma, the sister of Robert Guiscard (see GUISCARD), was one of the celebrated heroes of the first crusade, and was born after the middle of the 11th c. A.D. Some chroniclers profess to detail the events of his early life, describing him as the most accomplished youth of his time in athletic and military exercises, and of a wisdom far surpassing that of men of mature years, and as a partisan of his cousin Bohemond (q. v.) in the quarrel with their uncle, Roger (q. v.) of Sicily. But the first authentic information respecting him is that he raised a large body of men in Apulia and Calabria, and joined Bohemond, then on his way to the first crusade. The two cousins landed in Epirus, and first one and then the other made their submissions to the Greek emperor, Alexis. T.'s exploits on the way to Syria; his quarrel with Baldwin for the possession of Tarsus, and his subsequent chivalrous forbearance to, and rescue of, his rival; his wondrous valour before Antioch, where he killed no fewer than 700 infidels, transmitting the heads of 70 to the pope, and receiving a corresponding number of marks of silver in return; his vigorous repulse of the first sortie by the infidels from Jerusalem; his sad and lonely vigil on the Mount of Olives; and his gallantry at the storming of the sacred city, are all detailed by the numerous chroniclers of this epoch, in their usual style of extravagant laudation, but with a harmony which speaks favourably for their correct appreciation of his character. He was one of the claimants of the throne of Jerusalem, and was pacified by Godfrey (q. v.), the successful competitor, with the gift of some towns in Palestine, and the principality of Galilee or Tiberias. A brief quarrel with Baldwin, after Godfrey's death, petty combats with the infidels, and occasional wars with the other Christian princes who had settled in Syria and Palestine, occupied the remainder of his life, which was brought to a close at Antioch in 1112. Besides his own principality, he governed that of Antioch, belonging to his cousin Bohemond, from 1100. The fiery and energetic, but at the same time pious, sagacious, and forbearing chief whom the chroniclers present to us, has been considerably toned down by Tasso in his *Gerusalemme Liberata.*

TANGANYIKA, a lake of Eastern Central Africa, the northern end of which is 200 miles south-west of Victoria Nyanza. It lies between lat. 3° and 7° 45' S., long. of centre, 30° E.; surface, 1844 feet above the level of the sea; length, 320 miles; breadth, from 15 to 60 miles. In shape it resembles a leech, tapering towards the north. The explored portion, on the north-east, has elevated and populous shores. The water is fresh and deep. It was discovered by Captains Speke and Burton in 1858, when they arrived on its eastern shore, at Ujiji, about lat. 5° S. It has not been ascertained whether a supposed river flows into or out of its northern extremity.

TANGENT. See TRIGONOMETRY.

TA'NGHIN (*Tanghinia venenifera*, or *Cerbera Tanghin*), a tree of the natural order *Apocynaceæ*, a native of Madagascar. The fruit is a drupe, of which the kernel is so deadly a poison, that although not larger than an almond, one kernel is sufficient to destroy twenty people. It was used in Madagascar as an ordeal for the discovery of guilt or innocence, and with the general result of the death of those subjected to it. A little of the powdered kernel was placed on the tongue of the suspected person, and he was obliged to swallow it. Only those recovered whose stomachs quickly rejected the dose. The progress of Christianity and civilisation in Madagascar has led to a discontinuance of the use of this ordeal. A similar poison-ordeal is used in some parts of Africa. See ORDEAL and ERYTHROPHLÆUM.

TANGIE'R, a seaport of Morocco, on a small bay or inlet of the Straits of Gibraltar, 38 miles south-west of the town of that name. It is a small, ill-built town, situated on two hills; the houses—with the exception of the residences of foreign officials—being, as a rule, miserable edifices, and the streets being narrow and dirty. The town is surrounded by old walls, and protected by several forts. In 1863, 920 vessels, of 92,476 tons, and with cargoes the value of which amounted in all to £587,247, entered and cleared the port. T. was taken by the Portuguese in 1471, and ceded to the English in 1662, and held by them for 22 years. Pop. about 9500.

TANGLE, the common name of *Laminaria digitata* and *L. saccharina*, two species of sea-weed, natives of the British shores, growing on rocks in deep water. The stem is woody, the frond leathery, flat, and without a midrib. The woody stems are sometimes used for knife-handles, the blade being stuck in when the handle is soft, and held fast by its shrinking as it dries. The young stalks form an article of food, and are nutritious, owing apparently to the large quantity of gelatinous matter which they secrete. They are also used for feeding cattle. *L. potatorum*, a large species, supplies the aborigines of Australia with instruments, vessels, and food.

TANIS, the Tyrian name of the goddess Astarte (q. v.).

TA'NISTRY, an ancient Celtic custom of succession, which is generally described as devolving the right to inherit lands or honours on the oldest and worthiest of the blood. The tanist, or righdomna, was the heir-apparent of the monarchy, whom it was the practice to appoint during the lifetime of the sovereign; and there is no doubt that the nearest to the original stock was held to have a preferable claim, as contended by Bruce in his claim to the Scottish throne. The practice of electing a successor was also applied to the inheritance of land, and to succession to ecclesiastical offices.

TANJU'R, more commonly written TANJORE, an important town of India, in the presidency of Madras, 180 miles south-south-west of the city of that name, in the midst of an extensive plain, on one of the branches of the delta of the Kaveri. The town comprises two forts and several suburbs. The former are so connected that they may almost be regarded as one. The smaller of the two is a parallelogram in shape, and 600 yards in extreme length. It is joined on the north to the larger fort, which is circular in shape, and 1100 yards in greatest diameter. The walls of both are lofty and strong, and are surrounded by a ditch cut out of the solid stone. The principal edifices of T. are the Great Pagoda, esteemed the finest specimen of a pyramidal temple in Hindustan (see INDIAN ARCHITECTURE), and the palace of the rajah. Silks, muslins, and cottons are manufactured. Pop. about 90,000.—The province of Tanjûr, of which the town of the same name is capital, has an area of 3900 sq. m. and contains 1,676,100 inhabitants.

TANK-WORMS. The mud in Indian tanks has been found to abound in *Filariæ*, some of which closely resemble the guinea-worm infesting the human body. Although there is no positive evidence, there is extreme probability that these tank-worms are the origin of the guinea-worm. Dr. Carter, who has had much personal observation of the guinea-worm in India, 'argues, and apparently with good reason, *No tank-worm, no guinea-worm*. Persons who bathe in water in which the former is found may expect to have the latter.' Mr Bastian, who has written an excellent paper on the anatomy of the guinea-worm, states that there is an undoubted anatomical relation between it and the tank-worm. The real difficulty in the theory is that these tank-worms are widely diffused, while the guinea-worm is restricted in its localisation.

TANNAHILL, ROBERT, was born on the 3d June 1774, at Paisley, where his life was almost entirely passed in the humble occupation of a weaver. Very early he exhibited a taste for poetry, and out of his constant study of the works of Burns, Fergusson, and Ramsay, the ambition was developed in him of emulating these favourite authors. His poetry soon became known, and procured him a local celebrity, which, on the publication, in 1807, of a collection of his pieces (*Poems and Songs*; new and larger ed., with a memoir of the author, Glasgow, 1838), was ratified by a wider acceptance. But whilst his modest fame was extending itself, his life had an abrupt termination. He was found one morning (May 17, 1810) drowned in a canal near Paisley; and there seems almost no reason to doubt that his death was that of the suicide. A morbid melancholy which seems to have been inherent in his nature had gradually been growing upon him, and clouding his life with hopeless gloom. He died at the age of 36.

As a song-writer, T. continues to be remembered; and some few of his best pieces have established themselves as part of the musical repertory of the Scottish people. He has a genuine lyrical gift, much tenderness of sentiment, and a true eye and feeling for the simple effects of nature with which he was familiar. Of the force and passion of Burns, he has nothing; but in grace and sweetness, Burns himself has scarcely perhaps surpassed certain of his happier passages.

TANNHÄUSER, the subject of one of the most attractive German legends of the middle ages, is a knight who, in the course of his travels, comes to Venusberg (q. v.), and enters the cave-palace, to behold the wonders of the Lady Venus and her court. After having lived there for some time in every kind of delight, his conscience smites him. Invoking the Virgin Mary, he obtains leave of absence, and makes a pilgrimage to Rome, to Pope Urban, to seek, through confession and penance, remission of his sins, and escape from damnation. But the pope, who happens to have a wand in his hand, tells him that he can as little obtain God's mercy as that dry wand can become green again. Thereupon, T. departs in despair, and returns to the Lady Venus in the mountain. Three days afterwards, however, the wand begins to sprout and bear green leaves; and the pope immediately sends out messengers to every country, but in vain—T. can nowhere be found. Such is the story, as told in the popular ballad once common all over Germany, and even beyond it, and sung in the district of Entlibuch as late as the year 1830—the best version of which is in Uhland's *Alten hoch- und niederdeutschen*

Volksliedern (Stuttg. 1845). In the preface of the *Heldenbuch*, it is further added, that 'the faithful Eckhart'—a character in German heroic legends—sits before the mountain, and warns the people of its dangers. In this shape, the story may be traced as far back as the 14th c.; but the substance of the legend is much older, and goes back to the days of German paganism. Some traditions connect it with the Hoselberg or Hörselberg, near Eisenach, in which the Lady Holle or Holda (see BERCHTA) held her court, who, on her part again, seems to be identical with Freyja, the Scandinavian Venus. The peculiar mythological meaning of the saga, which has numerous points of contact with many other German traditions, has, however, never yet been thoroughly inquired into. Grimm sees in it a touching portrayal of the regret that lingered in the popular heart after the departing paganism, and of the sternness of the Christian priesthood in regard to it. Compare Kornmann, *Mons Veneris* (Fkf. 1614); Grässe, *Die Sage vom Ritter Tannhäuser* (Dres. and Leip. 1846). In later times, the saga has been put into poetical form, among others by Tieck, and made use of by R. Wagner in an opera. This idea of subterranean palaces in which the king or queen of dwarfs, pigmies, fairies, and so forth, held their court, seems to have been universal. Everywhere, stories are told of men being enticed to enter, and finding it difficult or altogether impossible ever again to obtain their liberty. See RHYMER, THOMAS. The visit of Ulysses to the isle of Calypso, and that of Circe, appear to be only modifications of the same idea.

About the middle of the 13th c., and contemporary with Pope Urban (Urban IV., 1261—1265), there lived in reality in Germany a Bavarian knight named Tannhäuser, who, as Neidhart relates, after returning from the wars, resided as Minnesinger (q. v.) at the court of the Austrian Duke Frederick II. the Quarrelsome. At the duke's death, and after having wasted his substance in dissipation, he resided partly with Duke Otto II. of Bavaria, and partly led a wandering life. T. has composed fine spirited ballads, which, however, shew the decay that had already set in in the Minnesinger's art. T.'s memory was held in high regard by the Meistersingers, who also preserved one of his measures; and it is quite possible that this T. may have been introduced into popular fiction, and have had his name worked into a myth, in which there is some resemblance to his actual fortunes; in which process, however, that old myth became transformed into the more modern saga. The poems of T. are published partly in the second part of the *Minnesinger* (published by Von der Hagen, Leip. 1838), and partly in the sixth vol. of Haupt's *Zeitschrift für deutsches Alterthum* (Leip. 1848).

TA'NNIC ACID, or TANNIN. Under these synonymous terms, chemists include a number of solid non-nitrogenous substances, consisting of carbon, hydrogen, and oxygen, some of which are crystalline, and others amorphous, and possessing no smell, but a well-marked astringent taste. They are soluble in water and alcohol, the solutions being acid, and yielding precipitates with most metallic oxides. A solution of gelatine is also precipitated by a solution of any of the tannic acids, and the gelatigenous tissue in raw hides is by an analogous process converted into leather. See GALLOTANNIC ACID. None of these acids are volatile; and when exposed to the action of heat, they decompose, and yield the so-called pyro-acids. The persalts of iron yield bluish-black or green precipitates with the tannic acids.

The members of this group are widely diffused throughout the vegetable kingdom. 'The bark and leaves of most forest trees, such as the oak, the elm, the willow, the horse-chestnut, and the pine—and of many fruit trees, such as the pear and plum, contain tannin in notable quantity. The wood and bark of many shrubs, such as the sumach and whortleberry, and the roots of the tormentilla and bistort, are also powerfully astringent, owing to the presence of one of the forms of tannin. Coffee and tea, as well as Paraguay tea, likewise contain a modification of this principle. All these bodies, except coffee, precipitate the persalts of iron of a bluish-black colour; or, if a free acid be present, the solution assumes a dark-green colour.' —Miller's *Organic Chemistry*, 2d ed. p. 400. The variety of tannin, or tannic acid, occurring in catechu and kino, produces a green precipitate with the persalts of iron; while that occurring in matricaria, rhatany, and the common nettle, produces a gray precipitate. The principal members of this group are—1. *Gallotannic acid*, or *Tannic acid*, $C_{27}H_{22}O_{17}$ (in the ordinary acceptation of the word), which is mainly obtained from the gall-nut, and has been described in a special article; 2. *Morutannic acid*, $C_{13}H_{10}O_6$, obtained from fustic (*Morus tinctoria*); 3. *Quinotannic acid*, $C_{42}H_{30}O_{35}$, obtained from cinchona bark; 4. *Quercitannic acid*, from oak bark; 5. *Mimotannic acid*, $C_{18}H_{18}O_{28}$, from catechu; and 6. *Kinotannic acid*, from kino; to which some chemists add a variety occurring in coffee and Paraguay tea, to which the term *Caffotannic acid* is given.

TANNING. See LEATHER.

TANSY (*Tanacetum*), a genus of plants of the natural order *Compositæ*, sub-order *Corymbiferæ*, allied to *Artemisia* (q. v.), and having hemispherical heads of flowers, with the florets all tubular, the receptacle naked, the pappus a slight membranous border. The species are pretty numerous, and are natives of the temperate parts of the Old World. COMMON T. (*T. vulgare*) is a native of Britain and of Continental Europe, growing in fields and by roadsides, river-banks, &c. It has long been generally cultivated in gardens. It is now naturalised,

Tansy (*Tanacetum vulgare*).

and pretty common, in many parts of North America. It is a perennial, from two to four feet high, with great abundance of deep-green, bipinnatifid, inciso-serrate leaves; the flowers in terminal corymbs, yellow, and rather small. The leaves and flowers have a strong aromatic smell and a bitter

taste. The young leaves are used for flavouring puddings, cakes, omelets, &c. The plant is also tonic and anthelmintic, and *Tansy tea* is an old popular medicine. Some curious old customs still linger in many parts of England connected with the use of *Tansy cakes* and *Tansy puddings* at Easter, which was originally intended to represent the use of bitter herbs at the Paschal feast. In some parishes of the counties of Devon and Dorset, the clerk carries round to every house a few white tansy cakes as an Easter offering after divine service on Good Friday, and receives a gratuity from each householder. In former times, both ecclesiastics and laics played at ball in the churches for tansy cake at Easter-tide. The highest dignitaries took part in this, and began the ball-playing, which went on during the antiphone, and was accompanied with dancing. After the ball-playing was over, all retired for refreshments; and a gammon of bacon was a standard dish, to signify abhorrence of the Jews. A tansy pudding was an essential part of the feast.—See Chambers's *Book of Days*.

TA'NTALUM (symb. Ta, equiv. 182) is a very rare metal, discovered in 1802 by Ekelberg in the Swedish minerals known as tantalite and yttrotantalite. It is so closely allied to columbium or niobium, that Wollaston regarded the two metals as identical, a view which was generally adopted till Rose disproved it. As it is of no practical importance, it is unnecessary to enter into any details regarding it.

TA'NTALUS, a character noted in Greek mythology for the punishment he suffered in the lower world. He is said to have been the son of Zeus by Pluto, and some accounts describe him as king of Argos or Corinth. Various reasons are assigned for his undergoing the severe punishment which he did, the most common being, that he divulged the divine counsels of Zeus, which the latter had communicated to him as secrets. In the lower world, he was afflicted with an insatiable thirst, and had to stand up to the chin in a lake, the waters of which receded whenever he tried to drink of them. Clusters of fruit hung over his head, which eluded his grasp whenever he endeavoured to reach them, his mind at the same time being kept in a state of constant terror lest a huge rock, suspended above his head, and ever threatening to fall, should crush him. T., or rather the punishment which he suffered, has supplied the English language with the very significant verb, 'tantalise.' T. was the father of Pelops, Broteas, and Niobe.

TANTALUS, a genus of birds of the family *Ardeidæ*, resembling storks in their feet and bill, except that the ridge of the bill is rounded, and its tip gradually curved downwards, and slightly notched on each side; a portion of the head, and sometimes of the neck, is bare. The AFRICAN T. (*T. ibis*) was long regarded as the Ibis (q. v.) of the ancient Egyptians, but it is rare in Egypt, and belongs chiefly to Senegal. It is much larger than the true ibis. The AMERICAN T., or WOOD IBIS (*T. loculator*), is as large as a stork, but more slender, white, with black quill and tail feathers, the naked skin of the head and neck black. It is found both in North and in South America. In the United States, it chiefly inhabits the swampy districts of the south.

TANTRA (from the Sanscrit *tan*, to believe, to have faith in; hence, literally, an instrument or means of faith) is a name of the sacred works of the worshippers of the female energy of the god S'iva. See S'ÂKTAS. A Tantra is said to comprise five subjects—the creation and destruction of the world, the worship of the gods, the attainment of all objects, magical rites for the acquirement of six superhuman faculties, and four modes of union with spirit by meditation. A variety of other subjects, however, are introduced into many of them, whilst some are limited to a single topic, as the mode of breathing in certain rites, the language of birds, beasts, &c. They always assume the form of a dialogue between S'iva and his wife, in one of her many forms, but mostly as *Umâ*, or *Pârvatî* (q. v.), in which the goddess questions the god as to the mode of performing various ceremonies, and the *mantras*, or prayers and incantations to be used in them. These he explains at length, and under solemn cautions that they involve a great mystery, on no account whatever to be divulged to the profane. The efficacy of these *mantras* is deemed to be all-powerful, and according to some Tantras, that of the faith in these revelations of S'iva so great, as to free a believer from the consequences of even the most atrocious sins. The followers of the Tantras profess to consider them as a fifth Veda (q. v.), and attribute to them equal antiquity and superior authority. Though such an antiquity, or even one approaching the age of the four Vedas, is entirely imaginary, the question of their date is nevertheless involved in obscurity. As Tantras are referred to in some of the *Purân'as* (q. v.), they must have preceded these; but as, on the one hand, the age of the Purân'as themselves is merely conjectural, and as there probably existed older Purân'as than those we possess now; and, on the other hand, as there might likewise have been older Tantras, from which the works now so called were compiled, the circumstance that Tantras are quoted by some Purân'as would not throw much light on the date of those now extant. It seems more significant, however, that the oldest known author of a glossary of classical words, Amarasinha (see *Lexicography*, under SANSCRIT LITERATURE), should have omitted from amongst the meanings he assigns to the word *tantra*, that of 'a sacred book;' whereas the later commentators on his work do not fail to supply this omission, which certainly would have been an extraordinary one had Tantras existed at the time of Amarasinha. If, then, this negative evidence has the value which it seems to have, the Tantras would, at all events, be later than the first centuries of the Christian era. The works of this class are very numerous, and it is to be regretted that Sanscrit philology, which has already investigated, more or less profoundly, nearly all the branches of Sanscrit literature, should hitherto have almost entirely neglected this particular branch of it. The principal Tantras are the *S'yâmârahasya*, *Rudrayâmala*, *Mantramahodadhi*, *S'âradâtilaka*, and *Kâlikâtantra*.—See H. H. Wilson, *A Sketch of the Religious Sects of the Hindus*, Works, vol. i., edited by Dr Rost (Lond. 1862).

TA'NTUM E'RGO, the hymn uniformly sung in the Roman Catholic Church at benediction with the Holy Sacrament. These are the first words of the penultimate strophe of the hymn *Pange Lingua*. The *Tantum Ergo* is the most popular of all the Eucharistic hymns of the Roman Catholic Church.

TANZIMAT, or TANSIMAT, the plural of the Arab word *tansim*, generally signifies 'regulations,' but in a special sense denotes the organic laws established by the Hatti-Sherif of Gulhane, in accordance with which the administration of the Turkish Empire is carried on. These organic laws, the first attempt at constitutional government in Turkey, were published by Sultan Abdul-Medjid in 1844, and treat of—1*st*, the political organisation of the empire, and the powers and jurisdiction of the chief officials and higher courts; 2*d*, administration

and finance; 3*d*, justice; 4*th*, military affairs. But the tanzimat was a dead letter, or nearly so, except in connection with the army; so that on 7th September 1854, the sultan found it necessary to publish a new ordinance, in which the complete carrying out of the tanzimat in all respects was commanded; and a commission was appointed to see that this was done.

TAORMI'NA (anc. *Tauromenium*), a town on the east coast of Sicily, situated on a narrow ledge or platform of rock, 900 feet above the sea, about 30 miles south-west of Messina. It consists mainly of a single street, more than a mile in length, is surrounded by a Saracenic wall, has numerous convents and churches, many picturesque palaces and mansions built in the middle ages, and numerous relics of antiquity, among which are very fine sepulchres, an aqueduct, tesselated pavements, remains of a 'Naumachia' and of a theatre, the last reckoned one of the most splendid ruins in Sicily, and commanding a view of almost unparalleled magnificence. T. has some trade in wine and hemp, and between 4000 and 5000 inhabitants.

Ancient *Tauromenium* was built after the destruction of Sicilian Naxos in 403 B.C., but the exact date is uncertain. It rapidly attained prosperity; but its history during the Greek and Roman period presents no striking features.

TAPA'JOS, an important river of Brazil, and an affluent of the Amazon, is formed by the confluence of the Arinos and the Juruena, both of which rise in the south of the province of Matto Grosso. After a northward course of upwards of 1100 miles in length, the T. falls into the Amazon, about 20 miles below the town of Santarem. In lat. about 7° 30′ S., it has a fall of 30 feet; but the interruptions to the navigation, which is said to reach to within a short distance of the source of the river, are few. A portage of only 18 miles separates the upper waters of the T. from those of the Paraguay.

TA'PESTRY (Fr. *tapisserie*), a kind of carpet-work for decorating walls and furniture. The art of working tapestry is extremely ancient, but we have little information about it until the time of the Saracens, who revived it, and brought it into notice. They, in all probability, only used tapestry as drapery or curtains for the courts of their houses; its use as a covering for walls seems to have been an invention of the Flemings previous to 1606, at which date it was introduced into France by Henry IV., who engaged Flemish artists to teach it. At that period, so generally was its origin attributed to the Saracens, that it was called *Sarrazinois*. The oldest piece in existence is that described under the name of the BAYEUX TAPESTRY (q. v.). At first, the Saracenic tapestries were only ornamented with flowers and geometric figures; but the Flemings aimed higher, and sought to enrich them with historic subjects of the highest order; and so important did this art become, that the most eminent masters in painting, from Raphael downwards, bestowed their greatest efforts upon cartoons to serve as copies for the tapestry-workers, of which the celebrated Raphael cartoons, formerly at Hampton Court, now in a gallery specially designed for them in the Kensington Museum, are illustrations (see CARTOON). After its first introduction into France by Henry IV. at the beginning of the 17th c., the art of making tapestry does not appear to have made much progress until the middle of that century, when a small establishment founded by the brothers Canaye on the premises formerly occupied by Jean Gobelin, a dyer of wool, was commenced, and was afterwards carried on by a Dutchman named Gluck and his assistants with such success, that it was suggested by Colbert, the minister of Louis XIV., that it should be taken under the king's patronage; in consequence of which the establishment was bought, and constituted a royal manufactory in 1667, under the management of M. Lebrun, who was the first director. A royal carpet-manufactory had been previously established in 1615; this was called La Savonnerie, from the previous use of the buildings for the manufacture of soap. The Savonnerie and the Gobelins were both carried on with great spirit by successive sovereigns, and were formed into one establishment in 1826, when the works of the Savonnerie were removed to the Gobelins, where this most interesting work is now carried to great perfection, and also at a minor establishment at Beauvais, in the department of Oise, where it is, however, worked in a different style and manner. At the Gobelins, a series of threads are arranged vertically in a frame like the warp of a loom, and the workman stands behind the frame, the pattern being placed behind him for reference. To produce the design, he has a number of wooden needles threaded with wool and silk of the colours required, and these are passed through the upright warp-threads, and brought back, so that each thread becomes covered with the necessary colour; and such is the extreme nicety with which this is done, and such the delicacy and multiplicity of the shades of colour employed, that but little difference can be detected between the tapestry picture and the painting from which it was copied. At Beauvais, the warp is placed horizontally, and the workman stands over it; this renders it necessary to cut off the ends on the upper surface, which is avoided in the other plan of working from behind. The Beauvais is, however, a style intermediate between tapestry and carpet-work, and the roughness of surface so produced has a good effect. Much fine tapestry was employed in former times in decorating the palaces and mansions of Great Britain, in many of which it is still seen in great beauty. The modern works of the Gobelins are distributed as presents by the government of France; they are not produced in great numbers, and are of great money value. The number of artists employed is about 120.

TA'PEWORM is a word popularly used in a vague sense to designate any worm of the group *Cestoidea* (see CESTOID WORMS). According to Dr Cobbold, upwards of 250 distinct forms of cestoid worms have been described, of which probably somewhat less than 200 may be regarded as really good species. These he divides into the three families of (1) *Tæniadæ*, or true tapeworms; (2) *Bothriocephalidæ*, and (3) *Tetrarhynchidæ*. For the natural history of the tapeworms generally, we must refer to the article CESTOID WORMS. We will here only remind the reader of the following points necessary for the due understanding of this article, and that every T. passes through several distinct phases during its life-history. 'In the ordinary colonial or tapeworm condition,' says Dr Cobbold, 'it has been termed the *strobila* (Van Beneden). The separate joints of which the strobila is composed are denominated *proglottides*, or zooids. The anterior segment forms the *head*, and remains barren, those of the neck and front part of the body being sexually immature during the process of strobile-formation. The mature proglottides at the caudal end are capable of realising an independent existence, and the eggs which they contain develop the six-hooked embryos, or *proscolices* (Van Beneden), in their interior. These latter become metamorphosed into *scolices* or nurses, representing the well-known cysticercal state, which, in its sterile or aborted condition, forms the common *hydatis*.'—*Entozoa*.

p. 105. During the greater part of their existence, the tapeworms are parasitic animals, the mature proglottides and eggs being free only during a comparatively short interval. They are mostly restricted in their distribution to the vertebrate animals, comparatively few of the invertebrates (excepting the cuttle-fish) appearing to harbour them in their adult condition, although the T. larvæ, nurses, or *scolices* probably abound in various invertebrate groups. In the human body, no less than ten species of T. occur, viz., eight *true tapeworms*, and two species of *Bothriocephalus;* and as four distinct species have been found in the Barbary ape, it is obvious that errors of diet, due to civilisation, are not the cause of these parasites. Amongst the animals with which we are most familiar, the species are plentiful in the common dog (and in true carnivora generally), in rats, and mice. The typical ruminants are almost constantly infested both by mature and immature forms; while the larger pachyderms, and solidungulates (the horse, ass, &c.), harbour only a few adult forms; but only larvæ appear to be known in swine. These worms appear to be as abundant in granivorous birds as in Carnivorous hawks, owls, &c. In the water-birds generally, the adult worms are very abundant, their larvæ existing in the food of such birds, in fishes, molluscs, &c. In reptiles, these worms are extremely rare, although other parasitic worms abound; while in fishes they are very abundant both in the adult and larval forms.

The *Tæniadæ*, or *true tapeworms*, may be distinguished from the other families of the order *Cestoidea* (cestoids or tapeworms in the popular sense) 'by the possession of a small distinct head, furnished with four simple oval or round suctorial discs (suckers), and commonly also with a more or less strongly pronounced rostellum (proboscis) placed at the summit in the median line. This prominence, when largely developed, becomes retractile, and when not in use, is lodged within a flask-shaped cavity, lined by a sheath, and supplied with special muscles; it is also very frequently armed with a single or double crown of horny chitinous hooks, there being occasionally as many as five or six separate circular rows of these organs. Attention to the number, relative size, and disposition of the hooks is often sufficient to determine the particular species. In nearly all cases, the reproductive orifices are situated at or near the margins of the joints which are bisexual.'—Cobbold, *op. cit.*, p. 109. The eight true tapeworms occurring in man are—(1) *Tænia solium*, Linnæus; (2) *T. mediocanellata*, Küchenmeister; (3) *T. acanthotrias*, Weinland; (4) *T. flavopuncta*, Weinland; (5) *T. nana*, Von Siebold; (6) *T. elliptica*, Batsch; (7) *T. marginata*, Batsch; (8) *T. echinococcus*, Von Siebold.

The *common tapeworm*, *Tænia solium*, derives its Linnæan title from the idea that it is always a solitary worm. Although this is commonly, it is not by any means always the case: Küchenmeister has several times found two or three together, and cases are recorded in which 30 and even 40 worms have been expelled from one patient. The full-grown T. (strobila) has been known from the earliest times, and is described by Hippocrates, Aristotle, and Pliny; but its organisation and mode of development have only been properly understood during the last few years. The segments of which it is composed vary in size, and number from 800 to 1000, the earlier immature ones being extremely narrow, and the sexually mature joints commencing at about the 450th segment. From 10 to 35 feet may be regarded as representing its ordinary length; its breadth at about the widest part being one-third of an inch. The head, which is seldom seen in the tapeworms exhibited in our museums, although the evacuation of the head with the rest of the worm is not very rare, is very small and

globular (about the size of a pin's head), with black pigment ingrained in it. On examining it with a low magnifying power, it displays four circular sucking discs, in front of which is a conical proboscis, armed with a double crown of hooks, from twenty-two to twenty-eight in each circular row. The head is succeeded by a very narrow neck, nearly half an inch in length, which is continued into the anterior or sexually immature part of the body, in which traces of segmentation first appear in the form of fine transverse lines, which are gradually replaced by visible joints. These joints or segments represent the body, and each mature segment contains both male and female organs of generation; and in addition to these structures, the entire series of joints is traversed by a set of vascular canals constituting the so-called aquiferous system, which consists of two main channels, one passing down on either side of the worm, and both being connected by transverse vessels, which occur singly at one end of every joint. It is only in the alimentary canal of man or some other animal that a T. of any kind can attain to sexual maturity; and in all of these the eggs are fecundated before being discharged. The expulsion of the eggs may take place in any of the following ways: First, the mature segments separate from each other, and passing out of the body, either with the ordinary evacuation of the bowels or independently, become decomposed, and set free the enclosed eggs. The single joints thus discharged undergo violent contraction after being expelled, which led to their being formerly mistaken for a distinct species of worm, to which the title *Vermes cucurbitini* was applied, from their resemblance to a pumpkin seed. There is a figure in Aitken's *Medicine*, 3d ed. vol. i. p. 815, shewing the joints

of a *Tænia mediocanellata* (which will be presently described) of the natural size, in various stages of contraction; and on examining the recently discharged excrement of a constipated dog, the same phenomenon may be very frequently observed. Secondly, the eggs may be discharged through the genital pore by pressure from any cause. It is only thus that we can account for the occasional (but very rare) co-existence of a *Cysticercus cellulosæ* (the embryo of the worm) and an adult T. in the intestinal canal of the human subject—an association which constitutes one of the most serious dangers which the matured worm can inflict upon its host, and one of the strongest indications for its removal. Thirdly and lastly, the mature joints sometimes appear to undergo disintegration within the intestine, and to liberate the eggs; but the conditions under which this disintegration occurs are unknown. In reference to the ultimate fate of the embryos *in ovo*, that are liberated in the intestinal canal, Dr Cobbold has informed the author of this article in a private communication, that, in his opinion, they do not migrate in the living host, except when by regurgitation they occasionally get into the stomach, when, after their shells have been dissolved by the gastric juice, the young organisms commence their wanderings. The mature segments are usually expelled from the human bowel at the rate of six or eight a day. Their vitality is prolonged by moisture, which favours the distribution of the liberated eggs over grass and other vegetables, or in water, which may be used as food or drink by animals. For a full description of the eggs, we must refer to Dr Cobbold's work. It is sufficient here to remark, that, in their mature condition, they 'present a globular figure, and are easily recognised by their remarkably thick shell, which surrounds the six-hooked embryo. They present an average diameter of $\frac{1}{851}$th of an inch, the shell itself measuring about $\frac{1}{4000}$th of an inch in thickness. After a while, by accident, as it were, a pig coming in the way of these embryos, or of the proglottides, is liable to swallow them along with matters taken in as food. The embryos, immediately on their being transferred to the digestive canal of the pig, escape from the egg-shells, and bore their way through the living

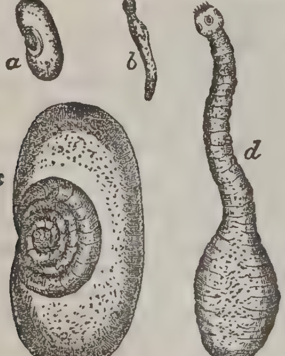

Fig. 3.

tissues of the animal, and having lodged themselves in the fatty parts of the flesh, they there rest to await their further transformations or destiny. The animal thus infected becomes measled, its flesh constituting the so-called measly pork. In this situation, the embryos drop their hooks, and become transformed into the *Cysticercus cellulosæ*. A portion of this measled meat being eaten by ourselves, either in a raw or imperfectly cooked condition, transfers the cysticercus to our own alimentary canal, in which locality the cysticercus attaches itself to the wall of the human intestine, and having secured a good anchorage, begins to grow at the lower or caudal extremity, producing numerous joints or buds form the strobila or tapeworm colony.'—Cobbol *Entozoa*, p. 221. In its fully mature stage, the *meas* presents the appearance of an elliptical hydatid, varying in size from that of a pea to that of a small kidney-bean, the average diameter being one-third of an inch. On dissecting or breaking up a measle, it will be seen that the great vesicular portion constitutes the bladder-like caudal extremity of the cysticercus, while the head, neck, and body can be drawn out so as to exhibit a vermiform character.

In the article GENERATIONS, ALTERNATION OF, it was stated that the group of phenomena included in that term would be further illustrated in the history of the tapeworm. From what has been already shewn, it appears that 'we have a simple alternation of generation in which the immediate product of the proglottis (or sexually matured zooid individual) is a six-hooked brood; by metamorphosis, the latter becomes transformed into the cysticercus, having a head with four suckers, and a double crown of hooks; and by gemmation, the latter gives rise to a whole colony (strobila) of individuals, the greater part of which are destined to become sexually mature—zooid individuals or proglottides. It will be observed, therefore, that the product of a single ovum is, in the first instance, a single non-sexual embryo; in the second phase, it becomes a non-sexual cysticercus (these two phases together constituting the protozooid); in the third change it gives off, by budding, numerous gemmules, most of them destined to be sexually mature individuals (or deuterozooids), in this way resembling their original parents. The relation and nature of these developmental changes may be further simplified by placing the various life phases in a tabulated form as follows:

(*a.*) Egg in all stages. } Protozooid
(*b.*) Six-hooked embryo = proscolex. }
